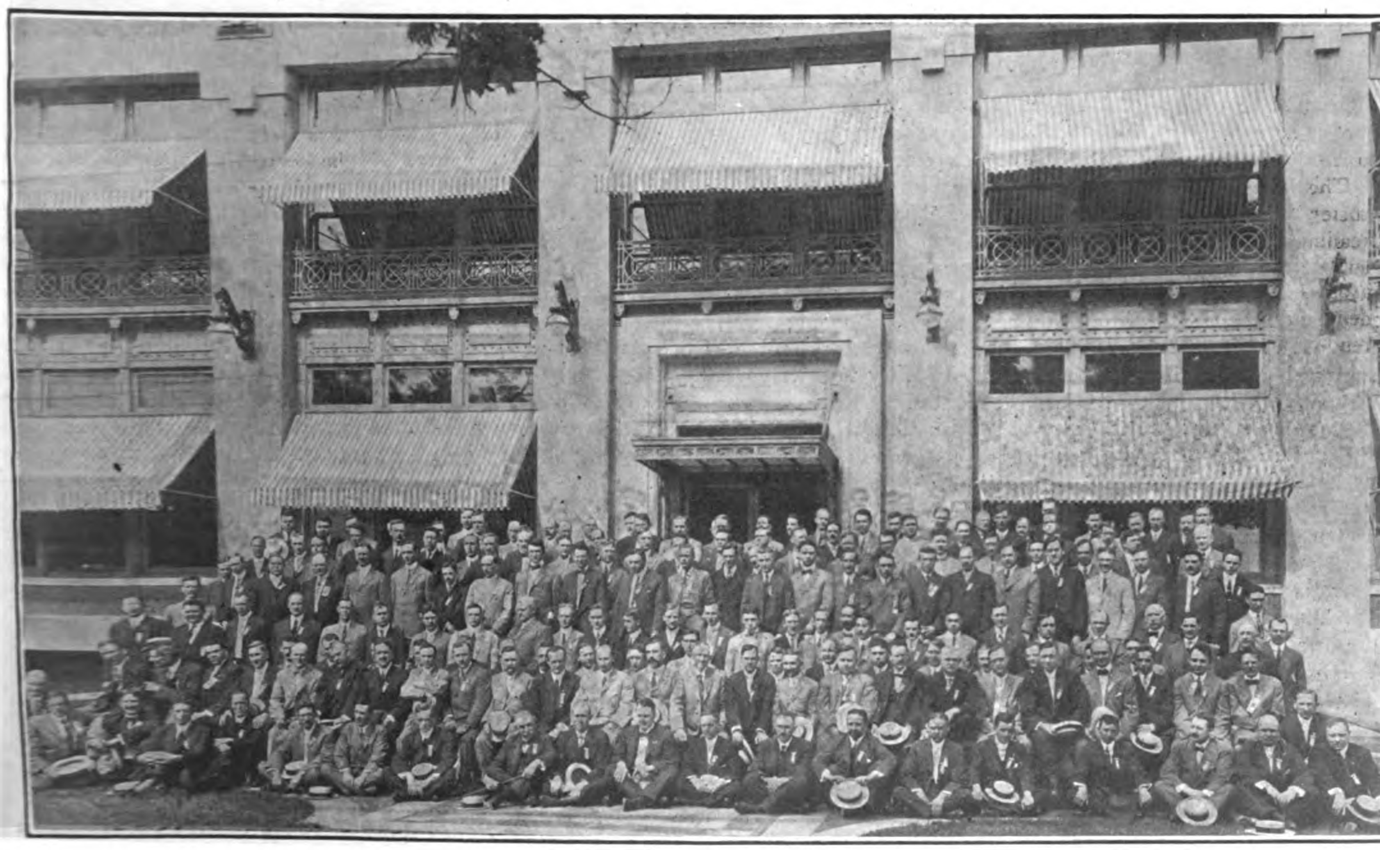
THE AUTOMOBILE

Standardization Is S.A.E. Slogan

Shipboard Convention of the Organization Most Successful in Its History—Four Hundred in Attendance—President Donaldson Outlines the Future Work—Several Valuable Papers Read and Discussed



S. A. E. delegates assembled in front of the Ford office building, Detroit, previous to an inspection of the plant

DETROIT, MICH., June 29—The regular midsummer meeting of the Society of Automobile Engineers ended one of the most useful sessions in its career when the steamboat City of Detroit landed at the dock at 9 o'clock this evening, after a two-day cruise to Mackinac Island and return, during which time the regular sessions of the society were held on ship. Never before in the history of automobile associations in America has there been such a unique meeting, namely, discussing automobile topics on board a ship on the high seas. Happily the one-half day's experience two years ago on shipboard with its cooling breeze and quietness suggested the possibilities of an entire convention on water rather than land, and when the hustling Detroit entertainment committee was assured of the meeting being held in the city, it did not take long to suggest the chartering of a ship for the society and their wives, sisters and daughters.

On Thursday morning, when the convention was called to order by President Donaldson in Convention Hall in Hotel Pontchartrain, it was found that a record breaking attendance was to be on hand and that with the ladies the number attend-

Convention hall in the Hotel Pontchartrain, Detroit, where the open meeting of the society was held

ing would be over the 400 mark. Undoubtedly the thought of combining a holiday with a business trip appealed very strongly to many in the society, and hosts of new faces were present.

The three-day session was one of the best in the life of the society from the viewpoint of work done. The work consisted of reading and discussing professional papers presented by members of the society; presenting of various reports by the standards committees, and acting on them; the reading of the president's address, and general routine business, including society reports on membership, finance, etc. The treasurer's report showed a balance of over $3,000 in the treasury in spite of the many heavy expenses of the last six months.

President Donaldson in his presidential address outlined the varied activities of the society during his period of tenureship, beginning with last January. He drew attention to the growth in membership, 209 members having been enrolled since the first of the year, this representing an increase of 60 per cent. over a similar period a year ago. He drew attention to the new headquarters in the Rubber building on Broadway, New York, near Columbus Circle, where open reading rooms are provided for the use of the members when in the metropolis. Since his installation in office the society has begun the publication of *The Bulletin,* a monthly organ, in which the official announcements are printed, as well as professional papers read before the society or its sub-sections in Detroit, Indianapolis, New York, etc. A feature of *The Bulletin* is the employment bureau, in which appear notices of vacant positions as well as notices of those in search of positions. The issuance of handbook data sheets continues from time to time as conditions demand. The society has secured the co-operation of the Automobile Club of America, which has placed its laboratory at the disposal of the society, and from which much valuable data is expected to come. The society during the past six months has been working hand in hand with the National Association of Automobile Manufacturers in the matter of standardizing truck features. The two complement each other, the National Association limiting its activities to merchandising the truck, covering warranties, loads and speeds, whereas the S. A. E. is working along technical lines with the hope of standardizing wheel sizes, tire sizes, and investigating generally the truck field. President Donaldson closed by drawing attention to the collection of historical data by the society and also touching at length on the work of the standardization committee of the society, which is thoroughly reviewed in this issue.

Undoubtedly the biggest factor in the convention was the lucid and emphatic exposition of the works of the standards committee of 100 and the various sub-committees. During the past six months there have been many caustic criticisms circulated on the work of the various standards committees, some engineers imagining that the society was going too far in the work and that some of the new standards set up were going to prove an injury to the industry. Chairman Henry Souther read an exhaustive paper on the subject, in which he clearly defined what is meant by standards, showed exactly what each sub-committee has been doing and pointed out tersely that the standardizing work is not the ideas of a few men, but of the entire industry. There are not any star-chamber proceedings in the matter; it is general discussion with the collection of data from all manufacturers. This matter is treated in detail in the opening pages of this issue.

Montagu on Standardization

AT the morning session, Lord Montagu, a British pioneer in motoring, who has been traveling in this country for several weeks, was present and addressed the society on the matter of standardization. He said in part:

"I esteem it a great honor to say a few words as I represent to a certain extent English automobilism. I listened to your president's address with great interest, as I saw in it reasonable standardization the same as is being aimed at today in England. But as in England, so here, you will have some difficulty if you try to raise standardization too high. There are several difficulties that will arise if you try to go too far in this work. In the first place your trade is very international, as can be seen on the main roads of England and France, where you see American-built cars in great numbers, and in considering standardization and replacement of parts you must take into consideration the standardization of the industry as it is carried on in England and France.

"Second: When people talk standardization they forget that all

invention must come as a spur of dissatisfaction. Some engineer has become dissatisfied with some part of the car and sets about to correct it; and in this great automobile movement it would be a disastrous error to place a limit on inventive genius, or, in a word, to say how the coat should be cut or how the hair should be trimmed, as it is only in certain directions that standardization must be carried on.

"Standardization has many advantages to the car maker, and the car buyer; but do not press it too far if you want to continue healthy rivalry and research work. Standardization pressed too far is bad.

"In England and France we are all endeavoring to standardize where possible. To be specific, we might have two, three or four sizes of wheels, but standardization work would simplify the work of wheel and tire makers. You can standardize on nuts, bolts, rivets, tubes, steering wheels, but if you go into carbureters and gearsets, both are today in their infancy, and you would make a mistake if you limited the activities of the engineers in any way in relation to these parts.

"Frequently outsiders see more than engineers in a problem of this nature; taking a survey of this great world-wide revolution of transportation—the automobile—you are talking on something that cannot come for a number of years.

"Take a parallel in locomotive engineering: Not until the last few years in England and France did they have any standardization, while here I see a difference, as a locomotive for hauling freight from Buffalo to Cleveland must be entirely different from one needed to haul from Kansas City to California over the mountains. The different loads and road conditions call for differences in locomotives.

"On behalf of the English engineers, we desire to co-operate in this great work, and we are glad to welcome you and your cars in our country, as it spurs our makers to higher efforts and we appreciate your cars on our shores."

List of the Papers Presented

NEW records were established at the different sessions by the discussion that followed the reading of professional papers and the presenting of reports. A year ago it was difficult to get members into discussion at former meetings, but during the present one the discussion was so great that the program was not half completed, and the reading of many papers was postponed to the midwinter meeting, which will be held in New York in January. The papers presented were:

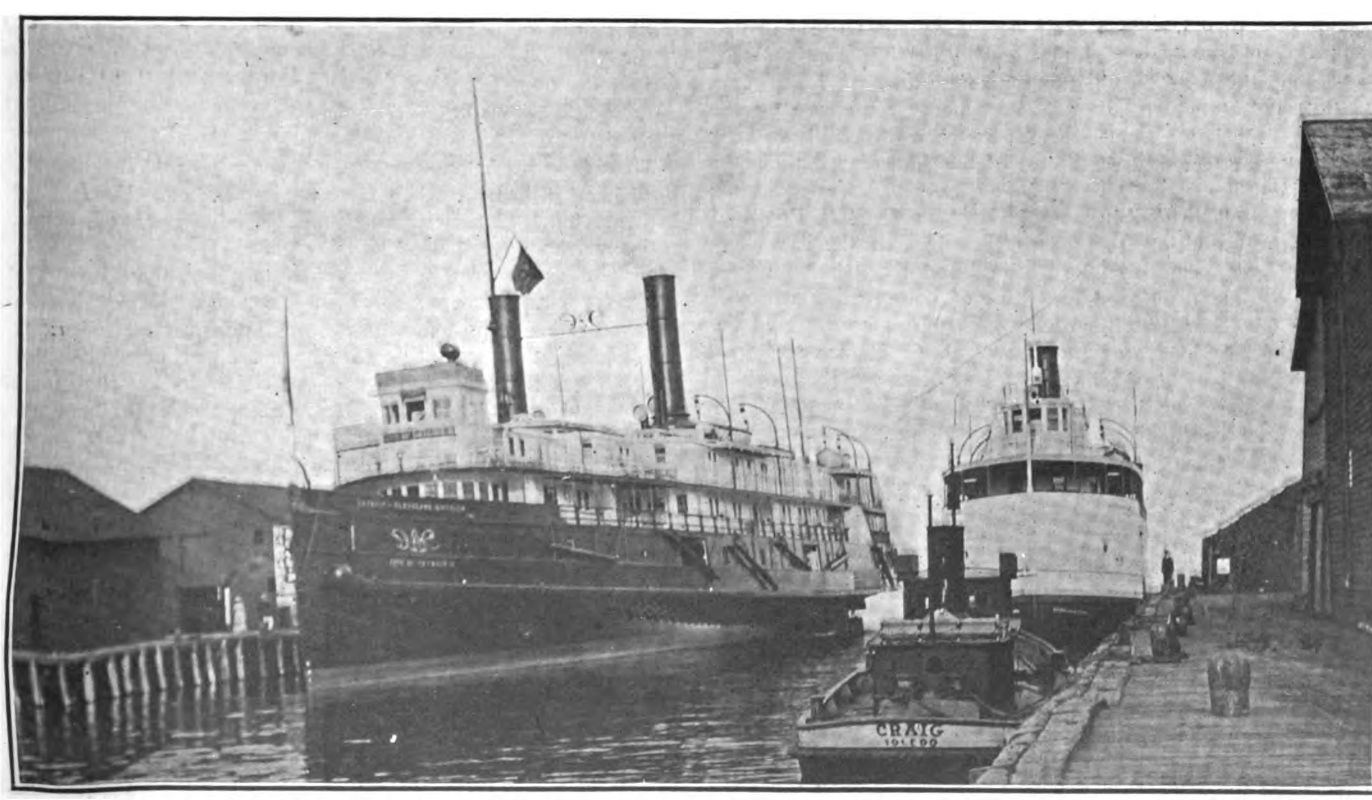
"Motor Sizes and Drive Ratios for Commercial Vehicles," by Eugene P. Batzell; "A Comprehensive Motor Test," by Herbert Chase; "Standardization and Co-operation in Motor Testing," by Herbert L. Connell, and "Worm Gears," by Frank Burgess.

Among the papers that were laid over until the midwinter session were: "The Effect of Relation of Bore and Stroke in Automobile Engines," by John Wilkinson; "Stability of Automobile Propeller Shafts," by J. M. Thomas; "Methods of Brake Capacity Determination," by S. I. Fekte, and "Leaf Springs," by L. J. Lane. Some of these articles will be considered next week.

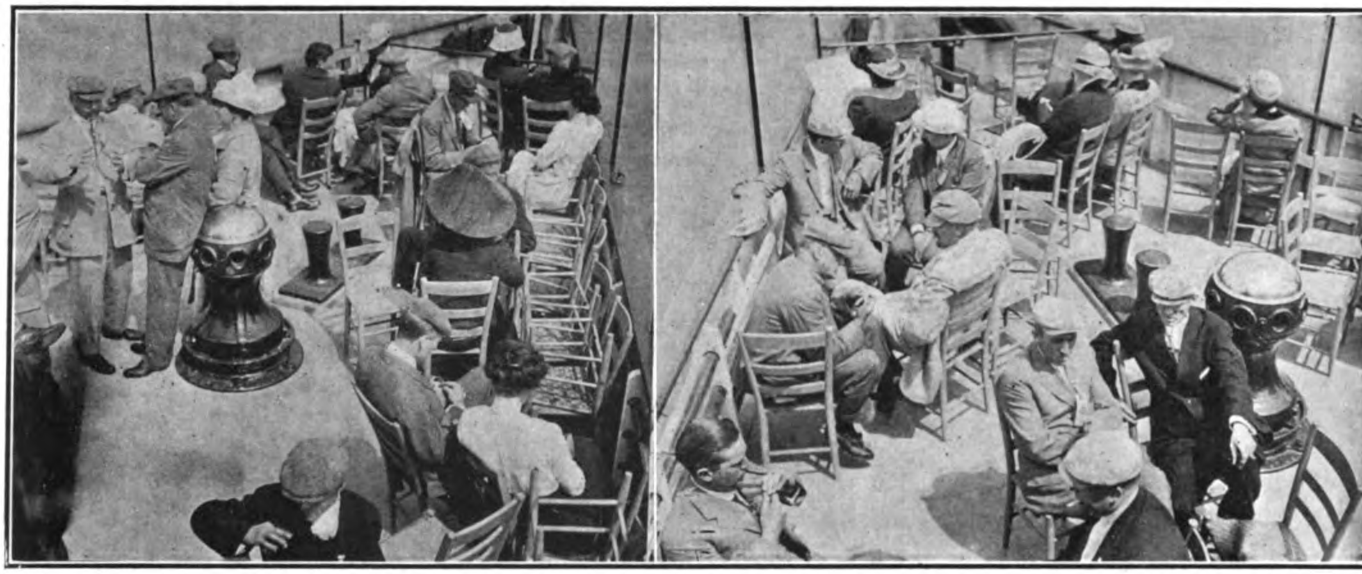
The presentation of reports of the various standard committees is always an important factor in regular sessions, but time did not permit to have all of the reports presented, several of these having to go over to January. Of paramount importance in the standard report field was the accepting by the society of the fourth report on carbureter fittings. This report has had a stormy career. It pertains to standardizing the size of flanges on carbureters for attachment to intake manifolds, so that the same intake manifold can be used for different makes of carbureters. At present it is generally necessary to make a new manifold when a carbureter is changed. The report also covers the matter of uniformity in connection for the gasoline pipe to the carbureter, and also the water connections with the carbureter jackets. After brief discussion the report was adopted.

The report on broaches was read by C. W. Spicer, and discussion postponed to a later session, but lack of time prevented a return to the matter, which will come up again at the midwinter session.

W. P. Kennedy, chairman of the committee on truck standards and also on wheel dimensions and fastenings for tire division, offered an oral report, stating that his committees had not any new recommendations to make, as there are minor details to settle in the present matter of standardized wheel sizes. The committee is making haste slowly, being sure of its ground in truck work before advancing. The committee wrote to wheel makers for trucks, asking them if they considered the work the



The good ship City of Detroit II which carried the engineers safely over the unsalted seas



The bow was a favorite gathering place for the engineers and the ladies. On the left Albert Champion is seen talking with his hands

committee was aiming to standardize as practical; if it required modifications; if it had been an advantage to them, and if it had caused any complications in their work. The correspondence asked if the new standards were resulting in a saving of time and money, and also what percentage of their product was being manufactured according to S. A. E. standards. The replies showed that 90 per cent. of the makers are working to the S. A. E. standards and all new work is being laid out according to such.

In reporting on the truck-standard division, Chairman Kennedy said that the committee was collecting data on truck specifications from all sources. The class papers had published many data sheets on trucks at show time, but there is need for much more. It is necessary to have complete and accurate information before certain steps can be taken toward standardization of parts, as has been accomplished in the touring car field. Several makers have objected to furnishing all of the data on the ground that they imagined their details of construction would be given country-wide circulation and so get into the hands of their competitors. The chairman assured them that any data obtained would be treated with the utmost confidence by the committee, much the same as stock-car specifications have been handled by the technical committee of the American Automobile Association.

E. T. Birdsall, in the absence of Chairman Cecil P. Poole, of the data-sheet division, told of the activities of the committee in collection of data for the society, and the tabulation and filing of it. He mentioned the work of co-operating with the United States Standard Bureau by the Detroit section and the benefits that would accrue therefrom. J. C. Heinze spoke on the advisability of establishing a society testing laboratory in Detroit, for the general use of the members. He suggested Detroit in preference to New York because of the large number of motor companies in the city, and also the proximity of Cleveland and Indianapolis. The matter was by motion referred to the council of the society for action.

Visit to Ford Company's Plant

The society accepted as recommended practice the Ediswan socket for electric automobile lights. Chairman Churchward stated before the general meeting of the standard committee that a full report could not be made as the sizes of sockets fixed upon by the division would sooner or later have to be made larger to meet the demand for stronger lights. Mr. Churchward stated that the 16-candlepower, 6-volt lamp, as suggested by members of the committee, will give two and one-half times the light of a three-quarter-inch acetylene-gas burner. He therefore believes the now generally used 16-candlepower lamp to be sufficiently large, and that as soon as larger lamps are used there will be legislation against them on account of their blinding other drivers.

President Donaldson

Ex-President Souther

Thursday afternoon was spent in an official visit to the Ford plant in Detroit, where open house was held. Henry Ford had previously intimated to Chairman Coffin of the entertainment committee that all locks had been thrown away for the afternoon and everything was wide open but the safe. The engineers spent over 2 hours in the plant. Much interest centered in the almost endless rows of automatic machines that continuously turn out parts for the Ford machines. Next of interest was the great number of multiple-spindle drills, those in some cases drilling holes into the four sides of a motor casting simultaneously. The assembly plant had its stores of interest in the quick dropping of the motor in position by three men; positioning the dash by a single man; mounting the front axle unit; a few minutes later attaching the rear axle unit, and finally bringing the body on and running the car away not long afterward. Many large additions are being made in providing for the extra output of next season.

The Indianapolis section of the S.A.E had a surprise in store for General Manager Coker F. Clarkson when through spokesman Wall it presented the general manager with an automobile as an indication of the appreciation the section bears for him. As the car had not been selected a tin toy one was presented. Mr. Clarkson was in complete ignorance of the plan to present him with an automobile, but it had been formed several months ago by the members.

President Donaldson's Address to the S.A.E. Convention

IN welcoming the members of the S. A. E. on the occasion of the semi-annual meeting of the society, your president is able to report that the affairs and activities of the Society are in a very satisfactory condition. The growth in influence of the society is reflected in the steady increase in membership, which now exceeds 1,300, a gain of about 60 per cent. over the total membership at the time of the 1911 midsummer meeting.

As you are aware, the Membership Committee has taken hold of the work vigorously and, with the active co-operation of the members, the results have been very gratifying. The work of the committee and the supervision of the council in passing upon the membership applications have been conducted in accordance with the provisions of the S. A. E. constitution.

Since the last meeting of the society in January, the headquarters in New York have been removed from 1451 Broadway, at Forty-first street, to the new twenty-story building, 1786 Broadway, corner of Fifty-eighth street, in the center of the metropolitan automobile district. A serious effort had been made to secure suitable quarters in the Engineering Societies Building, on Thirty-ninth street, but there was no unoccupied space that could be adapted to the uses of our society.

The present quarters are close to all means of transportation on Manhattan Island and provide a practical home for the society on an economical basis. The members' room on the twelfth floor, about 30 feet square, commands a magnificent view of Central Park, Columbus Circle, upper Broadway and the Hudson River. This room has been comfortably furnished for the exclusive use of the members and contains files of the automobile publications, writing desks, stationery, telephone, etc. The management urges all members to make frequent use of the quarters, especially those who live outside of New York and who have need of office facilities during their stay in the city. Secretary Coker F. Clarkson is prepared to give a hearty welcome to all visiting members.

Band of engineering redskins who entertained visitors

During the past three months the regular monthly publication styled the *S. A. E. Bulletin* has been undertaken and will be continued regularly hereafter. This provides a convenient means for periodical communication to the members of information about the activities of the society. It is in convenient, readable form, so that it can be preserved for constant reference and already has been found to be an effective substitute for the mimeographic sheets which are now used only when it is necessary to send out important notices between the dates of publication of the *S. A. E. Bulletin.*

A feature of the *S. A. E. Bulletin* is the listing of "Men Available" and "Positions Available" for the information of the members. This is the outward sign of an employment bureau maintained by the society for the service of which no fees are charged. The bureau has been very successful in filling vacancies for employers and finding positions for members suited to their capabilities.

Standards Development Has Been Great

In no other direction has the society so effectively contributed to engineering progress and the good of the automobile industry as in the development of the so-called standards. Of all the activities of the S. A. E., the standards work has been the most discussed—the most praised and the most abused. The society is fortunate in having for chairman of the Standards Committee a member who combines brawn with brain—although up to the present time his combats have been confined to intellectual encounter. An old proverb says that "The proof of the pudding is the chewing of the string," and so while the mastication of the string has occupied the exclusive attention of some, others have already digested the standardization plums and appear to be well fed and happy.

Talking it over between times—although all the conversation was not devoted to technical matters

Looking down upon Mackinac landing and harbor from the old fort on the heights

The angles of approach are a delightfully Euclidean study. Some even assert that the term "standard" is a misnomer, which assertion recalls to mind the Shakespearean reference to a rose. What is a standard? Astronomers tell us that some of the celestial bodies get askew when the notion seizes them so that even such fixed and irrevocable things as stars become unstandardized.

Coming down to earth, we have the case of monetary standards which are not really standard—witness the proposal to coin one-half-cent and three-cent pieces in America, and the abandonment of the guinea, the three-penny and four-penny pieces in England. And so with the standards of weights and measures—witness the sustained effort in England to substitute metric for imperial measures.

Recommended Practice Still Standard

Others suggest the abandonment of standards, foreseeing the impossibility of getting nation-wide acceptance. For such there is encouragement in the history of the metric system. About forty years after its adoption by France, the government was obliged to pass laws providing severe penalties for the use of any other system of weights and measures. The S. A. E. standards have had a more speedy acceptance, even if they have been only "accepted" by the society and not "adopted," a fine distinction that gives comfort to many able minds.

As a result of familiarity already gained in standards work, and having in mind the long continued and highly successful standards experience of the Master Car Builders' Association, the council of this society has decided that in future the conclusions reached by standards committees will be designated "Recommended Practice." When such practice is confirmed by general usage, the term "standard" may be applied. To suggest standards applicable in perpetuity is to assume a lack of information and capability on the part of those who will take up the work of construction and research when we are only a memory.

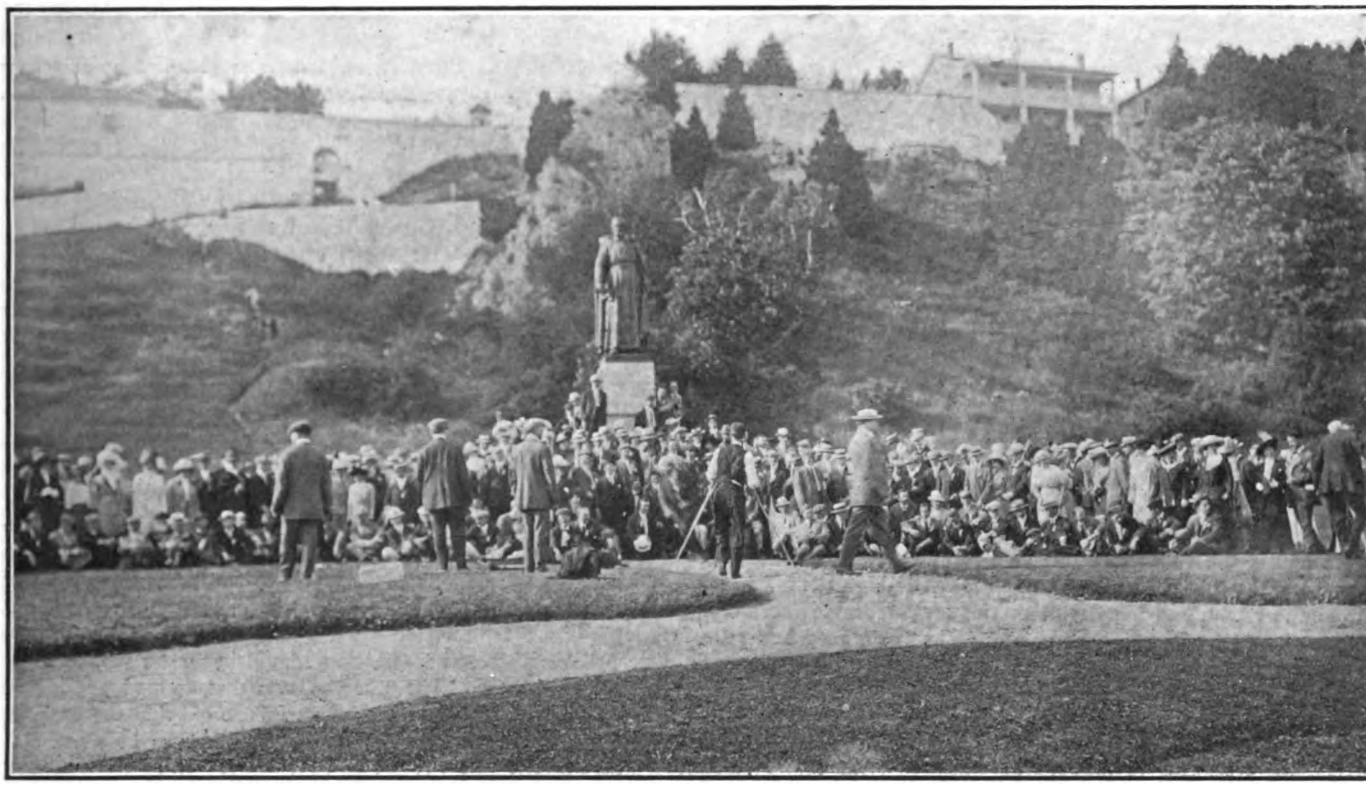
It will be the pleasure of the members to listen to a complete exposition of the scope and purpose of the Standards Committee's work by Chairman Henry Souther at the first professional session of this meeting.

The important work of revising and adding to the S. A. E. handbook has been entrusted to a new professional committee styled the Handbook and Data Sheet Committee. This committee has been selected with a view to the special experience of its members in such work and has now in its possession a large amount of engineering data which will be critically examined and edited for publication. As the work of this committee is one of the most important undertakings of the society—of direct benefit to a large majority of the members—the active co-operation of every member is invited. Contributions of data, whether in tabular or graphic form, or as memoranda, will be thankfully received by the committee. The data sheets already issued are of great value to automobile engineers and are really an indispensable part of the designers' and drafting room equipment.

Every member of this society recognizes that there are many obscure problems connected with the design and construction of motor vehicles that are still unsolved. The habit of mind which is best fitted to cope with problems of production is not the most efficient when applied to the consideration of abstractions. Much good work has been done in the service of motor car manufacturers, but there is always present, even unconsciously, the limiting effect of a salable product, which indeed is the ultimate purpose of the so-called experimental department of the automobile factory. It will, therefore, be of much interest to the members of the industry to know that the society is now in correspondence with the United States Bureau of Standards, in Washington, for the purpose of reaching a basis of agreement whereby the bureau can conduct scientific investigations of problems in carburetion, ignition and the like. It is unnecessary to lay an emphasis upon the value to the industry of determinations reached by the U. S. Bureau of Standards which is pre-eminently the scientific authority in its field in America.

Co-operation upon somewhat similar lines has also been promised by the laboratory of the Automobile Club of America, and the laboratory of the University of Michigan, both of which are well equipped in personnel and material to assure the most valuable results.

Another gratifying development of the standards work of the society is the approval of the S. A. E. motor truck wheel standards by the National Association of Automobile Manu-



The entire party assembled around Marquette's monument on the slope in front of Fort Mackinac

facturers. Also, at a recent conference between members of the S. A. E. Truck Standards Committee and the N. A. A. M. Commercial Vehicle Committee, an agreement was reached whereby the work of the two committees will be co-ordinated, the N. A. A. M. committee confining its investigations and recommendations to standards of a commercial character, and the S. A. E. committee to those of a more technical character, relating particularly to chassis construction. At this conference the cordial relations existing between the two great organizations in the automobile industry—the one commercial in character and the other technical—were strengthened and a united effort for the good of the industry agreed upon.

Your president recommends that a serious effort be made by the society to accumulate historical engineering data for preservation in our library. There are, doubtless, many drawings and photographs of early models now available which will have a constantly increasing historical value and which, owing to their obsolete character and the usual limitations of storage space in a manufacturer's office may be destroyed. It ought to be one of the functions of this society to collect and preserve such material and the co-operation of all members is invited.

In conclusion, your president believes that the society can view with satisfaction the technical work it has already accomplished and use this as an incentive to further and greater effort. As the representative of the technical branch of one of the greatest engineering industries in the United States it has a broad field for usefulness and achievement. And keeping step with its engineering progress the society can fulfill a high purpose in bringing into intimate association the technical men of the industry upon whom its very foundations now repose.

Reports on Standardization Committee Work

DETROIT, MICH., June 29—A standard is that which best endures the test of time; that which changes when demand necessitates, but otherwise stands towering aloft amid the maelstrom, an enduring beacon by which the masses shape their course.

Standardization is the last word in mental satisfaction: The mind craves completeness; it will endure the imperfect, the makeshift, the temporary, all of which become stepping stones to the eventual, only until it can go further towards the goal.

In mechanics standards are accepted practices in design. A score of automobile makers decide on a uniform size of magneto base, they vote their approval, and that size becomes a standard. It may be a standard for a year, for 5 years, or, perchance, for a century—it remains standard practice until those interested declare that it no longer possesses that completeness that conditions demand; then it may be altered into a new standard.

The automobile industry in America has done more to develop standardization in the last 2 years than any other existing industry. Here has been an infant industry, everybody rushing into it and everybody doing everything in a different way. Pedantic engineers refused to imitate established practices and went off at tangents; dark clouds arose. Everything became at sixes and sevens. Makers became laws unto themselves; engineering and manufacturing anarchy was invited.

One automobile engineer would make a water tubing 1-64 inch larger than another simply to be whimsical and different; another insisted upon a special spark-plug size; a third had 100 different sizes of lockwashers in his automobile, when 10 would have been better; to a fourth it was a different size of carbureter flange; a fifth demanded a wheel felloe 1-32 inch wider than his rival; and from Alpha to Omega multitudinous sizes and multitudinous shapes produced confusion and cost of manufacture that worked destruction to treasury reports wherever such prolific extravagances of engineering hallucinations were permitted.

At the crucial moment a solution presented itself. The Society of Automobile Engineers recognized the gravity of the situation, saw the needless cost to the manufacturer of such a promiscuous medley of shapes and sizes, saw the drain on the pocketbook of the owner for hard-to-obtain replacements, and, surveying the troubled waters, appointed an arbiter.

Frank Burgess faces camera

C. E. Duryea disagrees

It was a committee on standardization, 100 men selected from the automobile industry, men representing the manufacturer, men representing the consumer, and men representing both the producer and the consumer. This committee of 100 selected a leader, an engineer who had lived with the industry from its inception, Henry Souther. Once a head was selected, it organized for the fray, dividing into committees and sub-committees until the entire field was covered. Then began the campaign. Before standardization could come, present methods must be known. Huge data sheets were provided, sheets on which makers could give all of their sizes for parts, permissible variances in sizes, etc. These reached every factory from the least to the greatest. Some were filled out, some were not. Not until they got these sheets did many makers realize the hopeless situation they had unconsciously drifted into. The data collected were segregated and tabulated, and for the first time the gross irregularity of manufacture and design became apparent. The tabulations were distributed widespread over the industry, and so discussions and conferences eliminated hosts of constructions.

A new dawn was breaking. The light of standardization was breaking across the firmament. Instead of the hundred sizes, makers by vote agreed to accept two or three; the rest went into discard. Soon makers of tubing found it possible to fill orders from stock by return delivery, instead of having to put a special order through the mill, at big expense and long loss of time. Soon the car owner found standard parts creeping into his machine, parts that could be purchased in Galveston or Portland just as well as at the factory. Soon standardization became a boon to car owners as well as to manufacturers.

But there are conservatives and anarchists in every movement, and the standardization conservatives and anarchists soon exhibited themselves. Some engineers imagined that soon their positions would be eliminated, standardization would eliminate them. They imagined the end of their usefulness at hand. It looked to them that all was standardized, even inventive genius. Then opened a guerrilla warfare. There was some fighting in the open, but many preferred the bush tactics.

Souther on Standardization

Once more came a satisfying solution. It came only this week, and the war zone was the Mecca of the industry—Detroit. Chairman Souther, of the committee of 100, led the attack. From start to finish he reviewed the work of standardization by the Society of Automobile Engineers, showed the thousands of dollars it had saved the makers, showed the thousands of dollars it had saved the car dealers and showed the thousands of dollars it had saved the car owners in outlay and in time.

The occasion selected was the annual midsummer session of the society held on board ship between Detroit and Mackinac Island and return on Thursday, Friday and Saturday of this week. Nearly 200 members mustered for the attack, and when led into the fray the advocates of standardization presented so irresistible a battle line that the attacking force was routed.

Chairman Souther opened the engagement in mid-sea, the bosom of Lake Huron being the zone and the aft main cabin on board steamship City of Detroit II the immediate scene of activities. The opening shot was fired at 10 o'clock Friday morning, from which time for over 2 hours he outlined the work from its inception up to the present moment; and where conviction was then wanting, it was secured by a score or more of reinforcements who for a year or more have been making dollars for their factories by utilizing the advantages of standardization.

President Souther presented the work as follows:

The subject of standards and the work of the standards committee of the society seem to be so misunderstood to those not in close touch with the work that a paper of some length, which shall take up the matter in detail, seems desirable. There is a great variety of viewpoints taken by those who comment and criticise.

It is safe to say that all approve of some standardizing work and freely admit that some standards are possible. There is the class which believes that a standard, in order to be worth anything at all, must not be adopted or recommended until everything is known about the subject. In contrast, there is the class which seems to believe almost anything can be standardized and which would go to very great extremes in the matter. There is apparently a sharp division of opinion between these two groups. One believes that standardization should begin early in the history of an industry. The other believes that no standard is possible in an industry until such industry is so old that the probable changes in the proposed standard are few and far between.

Standardization Where Possible

The opinion that standardization should start early in the history of an industry has many arguments back of it. Perhaps the best one is that there are no partial standards that must be undone. The opposite view is that sufficient knowledge does not exist in a young industry to enable a standard to be adopted that will possess any enduring value. It is argued that frequent changes will be necessary and therefore no standard is possible.

In this last phase of the situation, the policy of the Society of Automobile Engineers seems to solve the question. It is believed by the council and those in charge of the society's work that standardization must be started as soon as possible. With this in view, committees having to do with the most recent things in the art are settling upon a few points that all can agree upon at the moment. Then there are a number of other items or points in construction or detail that are questionable as standards. Portions of the sub-committee considering the subject may believe that certain details ought to be standard and other portions of the committee may believe they should not. These

SOME STANDARDISMS

The adoption of a standard is not compulsory; it is voluntary.

Standards should be accepted as readily as possible and kept up-to-date by following the art closely and making such changes as time deems necessary.

To some men the word standardization means the same as the red flag to a bull.

Standardization is not intended to usurp the engineer's position but to facilitate his work.

A standard should represent the collective knowledge of all concerned, rather than the narrow viewpoint of one man or a small group of men.

Affirmative action and approval on the part of the S. A. E. as a whole carries with it the recommendation of the matter as standard.

Standardizing is not hampering inventive genius; it is helping it.

Sufficient knowledge does not exist in a young industry to enable a standard to be adopted that possesses an enduring value.

The records show that all standards have been changed; some of them very seldom and others frequently.

disputed points are fully discussed and the discussions put into the records of the society, so that all members may know what is being considered at the time.

Then there is a third class of information that it is clear to all cannot be used as a standard or as part of a standard. Nevertheless, much of it is excellent material from an engineering standpoint and may even some day come to the quality necessary to form a standard. Such material is put on record and forms part of the engineering knowledge of the society.

The springs division of the standards committee is at this time confronted in a marked degree by the foregoing conditions. There is apparently little that can be even suggested to the society as the basis for a standard; and yet a large amount of engineering data is being gathered by this sub-committee and placed before the members of the society for their information.

The life of a standard is the cause of much discussion. Some believe that if a standard is not everlasting it should not be designated standard, others that a standard is subject to change at any time. Those of the first school would probably adopt but very few standards, for the simple reason that in this age and industry evolution is so rapid that there would never be a time when it would appear that changes were not possible. Consequently, it is the belief of your standards committee that standards should be accepted as rapidly as possible and should be kept up to date by following the art closely and making such changes as may be necessary from time to time.

To me it seems that portions of a construction may be standardized at a given time and that other details must wait further developments. It is most desirable to have the few agreed points standardized rather than do nothing at all.

Makers Demand Standardization

Perhaps the word standard interferes with the understanding of this subject. For instance, a standard pound or kilogram remains the same forever; also the standard foot or meter. There can be no such thing as this in any industry that progresses. It would seem, therefore, that the word standard should be understood as applying not only to those objects which are never to be changed, but also to those that are standard for the time being.

Your committee realizes perfectly well that too many standards, or ill-considered standards, are worse than none at all, and that it must not go too fast. But it also realizes that there are certain things that must be standardized to save untold confusion. It is in receipt of occasional demands from members and from corporations that certain things be standardized. Just at present there is the sharpest possible demand from a large producer of truck axles that the society shall standardize the tread of trucks and a few other items related to the axle. The statement is made by this corporation that if some standard is not forthcoming at a very early date it will create its own.

The whole question of standardization is interesting to the engineering world. It is viewed with the most favor by those who have gone deepest into the subject.

A view of a standard apparently taken by some contemplates the fact that a standard once adopted by the Society of Automobile Engineers must be used by all its members or else they shall forfeit their rights to membership or citizenship or something else not expressed. This is certainly not the case. A standard, in order to be accepted, must have so much merit that engineers or producers or executives will see good reason for its acceptance. Good engineering design may be the reason why it is worthy of universal adoption; easy manufacture may be another reason why it should be adopted and become standard practice; and low cost is a reason why the business organization would say to the others involved that it must be adopted. As a matter of fact all three of these qualities will usually be found in any good standard. The adoption of a standard is not compulsory; it is voluntary.

There are many details that should not be standardized and many that cannot. For example, to set forth a detail standard design for an I-beam front axle or a front axle of any design or shape would be manifestly impossible. The shape and weight of an axle for any given car depend upon so many details connected with that particular car that it might be absolutely wrong for all others. Similarly, a set of transmission gears suitable for one car could never become the standard for all. A set of springs suitable for a given type of car is rarely right for any other; therefore, it is out of the question to attempt to standardize springs as a whole or sets of springs as a whole. A standard engine design would be equally absurd and ridiculous. Such a standard would presuppose absolute perfection in every detail.

Carl G. Fisher and William G. Wall D. F. Graham

SOME STANDARDISMS

It is out of the question to standardize springs as a whole or sets of springs as a whole.

Some think that because bearing dimensions are standardized that the materials are; nothing of the kind is possible.

All agree that there are altogether too many sizes of broaches and that standardizing should progress.

There is not any attempt to standardize carbureters, but simply carbureter flanges and gasoline and water connections.

It is a grave question as to how much of an automobile frame is susceptible of standardization.

When the lock washer standardization was started there were 700 different sizes and shapes of lock washers, and now after standardization there are twenty-eight.

Before standardization started there were over 1600 different sizes of tubing; now with standardization of sizes there are 161.

A construction or design that is good becomes standard rapidly.

After a period of probation, extending over an indefinite length of time, recommended practise may be promoted to a standard.

Discriminating Is Essential

There are many more details of a car that should not be standardized. To draw the line in a practical way between that which is fit material for standardization and that which is not is the work of your standards committee and of the whole society. A standard should certainly represent the collective knowledge of all concerned, rather than the narrow viewpoint of some one man or small group of men. Various interests must be involved. There are always at least two—the producer and the consumer. There may be several; for example, the producer of the raw material, the manufacturer who shapes it and, finally, the consumer of the finished article. There is usually the sales interest between the other interests.

The standards committee as a whole consists of 100 members. The membership is made up of men possessing every variety of

J. G. Perrin wore his smile

Howard Coffin looking for the right door

Kennedy is a trifle skeptical

knowledge in the automobile art; at least such is the intention. The standards committee as a whole is too large to consider originally each and every possible standard as a committee of the whole, and for this reason it has been divided into sub-committees or divisions, consisting of a relatively small number of men, all of whom are interested in and qualified on the particular topic being considered. These divisions are made up as far as possible, and where necessary, of consumers and producers of the object or part under consideration. The chairman of the division, as a rule, suggests certain standards or possible standards. These suggestions are considered at meetings and through correspondence. The consumer expresses his objections to any proposed standard and the producer also states his. Providing they do not get together unanimously, there can be no fully effective standard.

Once a report is made by one of these divisions or sub-committees it is submitted to the standards committee as a whole. The subject matter is put before them in writing and also in open meeting. If the standards committee as a whole approves of the work of the division committee, then the matter goes to the council of the society, carrying the standards committee's recommendation for acceptance. The council decides whether or not it shall be put before the whole society in open meeting for discussion. If so, a printed report is prepared and laid before the whole membership of the society, so that all may be familiar with the substance of the proposed standard. Discussion is invited in every possible manner and adverse criticism usually causes the report to be returned to its division for reconsideration or alteration.

Standards Are Not Unalterable

Affirmative action and approval on the part of the society as a whole, by those present, carries with it the recommendation of the matter as standard. It is then put on record in the Transactions of the society and placed before the membership, for ready reference, in data sheet form in the handbook. This, as already stated, does not mean that the standard can never be changed. The sub-committee are not discharged, but continue their work whenever there is a need for any further change or advance. Every change must receive the same careful scrutiny of sub-committee, full committee, council and society before being recommended.

It seems advisable to summarize the work of the various divisions of the standards committee at this time. Some progress has been made and some standards have been accepted, but there are many more in process of consideration.

As stated, these sub-committees or divisions do not go out of existence because their work has apparently been completed. They are continued in case any new developments in their line arise. There is no better illustration of this than the Aluminum and Copper Alloys Division. Bearing in mind that this division is considering and recommending aluminum and copper alloys, it is made up of four producers and five consumers. In meetings and by correspondence the questions pertaining to this line of work were thoroughly discussed and the conclusion reached that the alloys which they have recommended are suitable ones for the purposes intended. The producing element of the division agrees that it is able to furnish, commercially, alloys containing no more impurities than permitted by the *Society of Automobile Engineers'* specifications. The consuming element has testified, by its acquiescence to these recommendations, that it is satisfied these alloys can be purchased at a right price and that they can be manufactured into the articles for which they are intended without undue cost.

Standardization Helps Buyers

This is very valuable information for the members of the *Society of Automobile Engineers*, whether the results be called a standard or not. It means that a purchasing agent buying for any of the engineers present will be safe in calling for bids for alloys of aluminum or copper in accordance with the specifications as printed. The purchasing department is perfectly sure that it will not be laughed at by the producer because in its ignorance of the technicalities involved it is asking for something that is impossible. It is certain that no fancy price can be justly asked for alloys in accordance with the compositions specified. The production manager knows that he is not going to have any undue difficulty in machining these alloys, because they are made in accordance with the consensus of opinion of those who are experts in the matter. In other words, they are tried alloys, alloys that have been found to be reliable, strong, easy-machining and reasonable in price. The work of this division is finished for the present, but its members are still waiting for any developments in the art.

The ball and roller bearing division has made several reports and has recommended several standards, some of which have been accepted. The work is by no means complete. There are many difficult problems before the division; problems that are delicate and that require careful, conservative scrutiny before any action can be recommended. This division has been able to decide and recommend a nomenclature for bearings of the annular ball type. Any one desiring to order a bearing of a certain size knows in detail just what he will get. The matter is much simplified in this respect.

The diameter of the bore, diameter of exterior, and axial length of the bearing are clearly defined. Any designer or any draftsman is able to incorporate in his design and drawings definite details with the assurance that what he has pictured may be purchased without extra cost. Many hundreds of measurements are being taken by consumers of ball bearings, to learn what is reasonable and to ascertain what tolerances are permissible and yet will not interfere with the interchangeability of the co-operating parts used by the consumer.

The producer of the ball bearing is equally interested. He wants as great a tolerance as is permissible in order that his manufacturing costs and his rejections, because of inaccuracies, may not be too great.

These two interests are coming together and it is fairly well established at this time that they can agree and that the tolerance under which it will be commercially possible for the producer to work is not too great for the manufacturing accuracy of the consumer. It should be borne in mind that no attempt is being made by producers or consumers to recommend how large a bearing an engineer shall use for any given purpose. That is engineering knowledge; and engineering knowledge cannot be standardized in that sense. One engineer may consider that a factor of safety of ten is necessary under his peculiar conditions. Another may consider that a factor of safety of two is safe under his conditions. Both are equally anxious to know just what a given bearing is like as to shape and dimensions.

To Help Broach Manufacturer

The broaches division is endeavoring to simplify the situation in such a manner that any purchaser may have hope of finding in stock at a reasonable price the broaches necessary for his work. As it is to-day, the broach manufacturer does not dare to carry a stock supply, as does, for example, the manufacturer of twist drills. He has learned by experience that the designer of broached holes will probably call for some peculiarity of detail that will demand a special broach. If a designer has laid down a hole showing corners cut off considerably, the broach must be made accordingly or the gears, for example, will not fit the shaft.

The number of splines and the shape of the splines are being considered; whether three, six or some other number is desirable. It is developing that this is a matter of engineering knowledge, and it may be that this division will decide not to recommend any particular number of splines, but will recommend some definite proportion of depth or width for the spline. All of this can only be possible by entire agreement among all those interested in the subject.

The carbureter fittings division has not completed its work. The definite object of the division is to minimize complication in connection with carbureter fittings. It is a fact well known to automobile engineers, repairmen, and to every one else who has anything to do with carbureters that there are nearly as many designs of carbureter flanges as there are carbureters, and that to substitute one carbureter for another, on any given engine, means some special machine work or fitting. This complication must be done away with; complication means trouble and expense.

This division is not attempting to design or standardize carbureters. It is attempting to standardize carbureter flanges, and gasoline and water connections, so that all these connections may be readily obtained and readily interchanged.

Carbureter Standards Endure

A draftsman may safely incorporate in the design of an engine such flanges and connections as the standards or recommended practice will show. He will be taking no chances and there will be no experiments involved. And the designer need not fear that his engine will be defective because of inferior carbureter connections. Such standards as these ought to endure for many years or until there is a radical departure from our present system of carburetion.

The work undertaken by the frame sections division is a very difficult one. It is a grave question as to how much about an automobile frame is susceptible of standardization. It was learned that there was a good opportunity for standardizing work; that there was an immense number of shapes differing one from another only very slightly. For example, there were some 700 different curves at the front and rear ends of frames, many of them very much alike. This necessitated a tremendous number of dies and all the attendant expense. Nevertheless, the division has found that the degree of curve depends upon several other items in the design of the automobile; the distance above the ground, the desired flexibility of the springs, including their length and curvature, the method of attaching to axles, method of attaching to the frame, and numerous other details. It has not yet been found possible to arrive at any acceptable standards in these respects, although they would seem very desirable on the face of it.

From year to year the shape of the body changes and necessitates a change in the shape of the frame side bars, perhaps even the weight, thickness and width of the side bars. New methods of construction are discovered, such as spot welding and various other means of joining members. More daring engineering is

Howard Marmon ready to object — R. H. Rosenberg incredulous — E. T. Birdsall waits for a reply undertaken and the cross members are incorporated with the side members. All of these details mean change of shape and design. This is one of the best illustrations of the fact that the engineer and his knowledge cannot be standardized. Year after year the engineer must devote his time and energy to the design of a frame which will suit his own particular job, and the draftsman must be carefully guided in every detail in order that the proper frame may be produced. This is not one of the cases where the draftsman can be sent to a data book for standard detail.

The gear tooth shapes division has made no recommendations as yet. It has before it a study of pure engineering, particularly relating to the shape of gear teeth. The automobile engineer knows perhaps better than any other engineer the great importance of exactness as to the shape of the teeth of gears, spur, bevel and spiral. Noise must be eliminated from an automobile, and poor gears are productive of most disagreeable noises.

The work of the iron and steel division is a continuation of that undertaken by the mechanical representatives of the companies that formed the Association of Licensed Automobile Manufacturers. Seven years ago the subject of materials suitable for automobile construction came up for discussion. Their own experience and practices were discussed, and metallurgists and representatives of the steel companies were heard. These men came before the meetings and gave to the members up-to-date information as to the progress of the steelmaking art, and upon this foundation and its yearly development the iron and steel division has built its reports.

Standard Steel Specifications

Specifications for all steels likely to be used by the automobile manufacturer are now before the membership, having been accepted by the society. Engineers may now turn to these specifications and learn what is commercially available and what is safe and reasonable to be incorporated in automobiles. Purchasing agents may safely take these specifications and order materials accordingly. They may feel assured that the materials are not difficult to get and should not carry a fancy price.

It must be borne in mind that these specifications have been closely scrutinized by producers who have been furnishing steel to the automobile industry since its beginning. Equally close scrutiny has been given them by the purchasers who have been buying similar steels for a long time. Both parties have agreed that they are willing to do business with each other on the basis of these specifications, which is very valuable information for our members.

Apart from these specifications, the division has also thought it wise to recommend the printing of certain information as to the proper treatment and handling of the steels specified. What may be expected under certain conditions of treatment and handling has been pointed out.

The reason for the existence of the lock washers division is a very practical one. The lock washer manufacturers found themselves in a very trying position. Every design that came into their office for quotation proved to be a little bit different from any other design previously received. One manufacturer stated that at the time this division was proposed there were some 700 sizes and shapes of lock washers on his books and that, from his standpoint, the situation was absurd. At the same time he did not dare suggest the use of stock lock washers to any of the engineers calling for particular shapes or sizes, for fear of offending the engineer and for fear the engineer had some very good reason for demanding certain very specific details or shapes. There are now 28 sizes of standard S. A. E. lock washers, 16 of the heavy type and 12 of the light type, and these will satisfy all the demands of the automobile industry with the exception of a few special cases.

The benefit of the work of this division permits of no discussion. The engineer, the draftsman, the purchasing agent and the manufacturer are all relieved of much detail work. The engineer instructs his draftsmen to use S. A. E. standard lock washers as far as possible; the draftsman looks in his handbook or in the society transactions and finds the design of the washer and incorporates it in his drawing; the purchasing agent orders a certain number of S. A. E. standard lock washers for a given bolt or screw; the lock washer manufacturer buys his steel of suitable shape from the rolling mill to produce standard washers, and when the order reaches him is able to furnish the standard article promptly.

The nomenclature division is one that is endeavoring to simplify the nomenclature applying to the various parts of an automobile. There is no end of confusion between engineering department and production department, between producers and others, and, in fact, throughout the industry as the result of lack of calling the same things by a uniform name.

The work of the seamless steel tubes division is also the completion of the solution of a problem undertaken by the Association of Licensed Automobile Manufacturers. There is no question about the extreme value of the work of the division and its predecessor. The number of tubing sizes has been reduced enormously—from over 1,600 down to the present number, 161. There is no reason why a designer or draftsman cannot work out any design incorporating one of the S. A. E. standard sizes. This is being done almost universally, and the sheet showing the stock sizes may be found in nearly all the drafting rooms of the industry.

There was a time when the tubing manufacturers received orders for tubing differing in wall thickness or diameter only by thousandths and they were obliged to draw special sizes for these special orders. That day has gone by and it is fair to say that the work of this division is nearly finished.

The sheet metals division has made considerable progress in its work, which has been that of collecting into one document or set of documents data never theretofore appearing together and distributed in any general way. There is a sharp demand from purchasers of sheet metal for more information from this division. It appears that purchasers supposedly well informed as to the purchasing of sheet metals are sometimes confronted with a new demand or a new use. A purchaser knows in a way what he wants, but suddenly finds that he does not know how to ask for it to get just what is desired. The customs and trade names and practices of the men in the sheet metal industry are obscure and confusing. They do not seem to use uniform practices in their industry.

The task before the springs division is an exceedingly difficult one. It will never be possible to standardize a full set of springs, for very obvious reasons. Every engineer has his own idea of flexibility and as to the many details of the length, shape and number of leaves in a spring. Nevertheless, it seems to be possible to standardize certain features of spring construction.

Much of the work of the division is sure to take the form of notes on good spring practice. As stated earlier in this paper, the division has done considerable work in connection with nomenclature, the width of springs, the sizes and proportions of center bolts, nibs, rebound clips, threads, specifications for ordering leaf springs, etc.

Truck Committee Collecting Data

The truck standards division will attempt to recommend standards for a new industry as fast as it can arrive at definite conclusions. At any rate, it is accumulating all the data possible relating to trucks, and these data will be immediately available and result in sufficient knowledge to enable us to recommend any reasonable standards that may be called for.

How much can be standardized and how rapidly the work can be done remains to be seen. The division is on duty with the purpose of advancing as rapidly as seems safe. It would seem that if axle builders can attempt to standardize their output at this time, the engineers who will purchase and use the axles ought certainly to have a hand in the effort. The axle manufacturers express their willingness at this time to modify their designs in deference to the ideas of the engineers. But if the matter is delayed too long they will not be so willing, and the inevitable result will be friction between consumers and producers.

The work of the wheel dimensions and fastenings for tires division has been startling in its success. The situation was apparently an impossible one when the division took up its labors. There were a dozen or more makes of tires and styles of tires, and for every nominal size there was a different actual size. The differences were small but important in the mind of each of the manufacturers of the tires. The conditions existing in the truck factories were intolerable. It was common for a truck manufacturer to have from five to fifteen trucks standing ready for delivery with the exception of wheels and tires. Special wheels had to be ordered and the order depended absolutely upon the tire specification. There was no possibility of stocking with either the wood wheels or the tires.

Demands reached the division from all sides—particularly from the manufacturers of trucks—asking that something be done. The work has been done and the result is already perceptible. The tire people are satisfied, the wood wheel people are satisfied, and the manufacturers and producers of trucks particularly are satisfied. Certain small details are still under consideration, but so many of the important details have been handled successfully that the former now seem small and insignificant to all concerned.

The spark plug shell is a standard which also came from the A. L. A. M. The miscellaneous division was called upon to specify a tolerance for the thread, so that the plugs would be interchangeable in threaded holes. This demand came from the consumer of the spark plugs, and definite knowledge and a definite practice must be established. The division felt that the thread should measure zero plus and .003 inch minus. As soon as this was tried, it was found that a standard method of measuring would have to be decided upon.

All of this sounds like small work—too much a matter of detail—but, as a matter of fact, once these details are taken proper care of, an amount of friction out of proportion to the size of the detail will disappear. The spark plug manufacturers are just as keen for this accurate knowledge as the users of the plugs. Some body of men must establish a standard practice, and there is no better body of men to do it than the miscellaneous division of the standards committee.

Some years ago a demand for a fine screw thread was felt. A committee of the A. L. A. M. answered this demand and established a standard. The screw companies took it up with some reservation. Consequently, the producers of screws and the consumers of screws did not get together fully at the time in question. The differences were slight and have since been reconciled, and the standard as it is now accepted by the society is one that has been adopted by both producer and consumer without reservation.

To Standardize Gearshift Gates

Standardization of gear shift gates was proposed to the miscellaneous division insistently by several designers. The division did not believe it possible to standardize any such detail, but after full discussion the matter was handled by a recommendation of the division as to preferred practice. Sketches indicate the several possible choices and the preferred practice may be followed by all who want to get as near as possible to standard construction. Should this preferred practice prove, by general and constant use, to be a decided advantage, it is not unlikely that it might become standard in fact if not by recommendation of the division. A construction or design that is good becomes standard rapidly.

Magneto Dimensions—Here is a subject that has been an annual target for criticism. Motor builders and car builders cannot understand why the magneto people cannot get together and make their instruments in such a way that they may be interchanged easily on an engine or in any car. The miscellaneous division has brought about the acceptance of two extensive tables of dimensions of magnetos, one for 4 and one for 6-cylinder engines, which tables differ as to two items only. At present a designer is able to so arrange his motor as to accommodate the largest magneto found in the tabulated information given. By so doing it is possible to locate all the smaller instruments in the same space. There is no difference except as to taper of shaft, in the case of the 4 and the 6-cylinder instruments, and a slight difference in the distance from the center of the two front base-plate holes to the large end of the taper shaft. The latter difference is but a millimeter, and may be reconciled by elongating the hole.

General discussion on the merits of standardization followed:

Charles E. Duryea, C. E. Duryea Company, said: I have nothing to say but appreciation of the work the standards committees have been doing. I have seen but one word that I wish to criticize in the entire report and that is "tread." We should use gauge to designate the distance between the right-hand wheel and the left-hand wheel, as used in railroad practise. The word tread really refers to the width of the individual wheel or tire.

H. W. Alden, Timken-Detroit Axle Company—Two years ago at the midsummer session of the society in Detroit there was criticism on the undue activity of the S. A. E. in its standardization work, which criticism was felt keenly by the council and the old members of the society. We brought matters to a head and had a vote. In the last six months the standardization work has called forth much criticism, some good and some caustic. I think that right now we should get the general view of the members of the society on the work, whether they are in favor of or against the work.

Coffin Points Out Some Difficulties

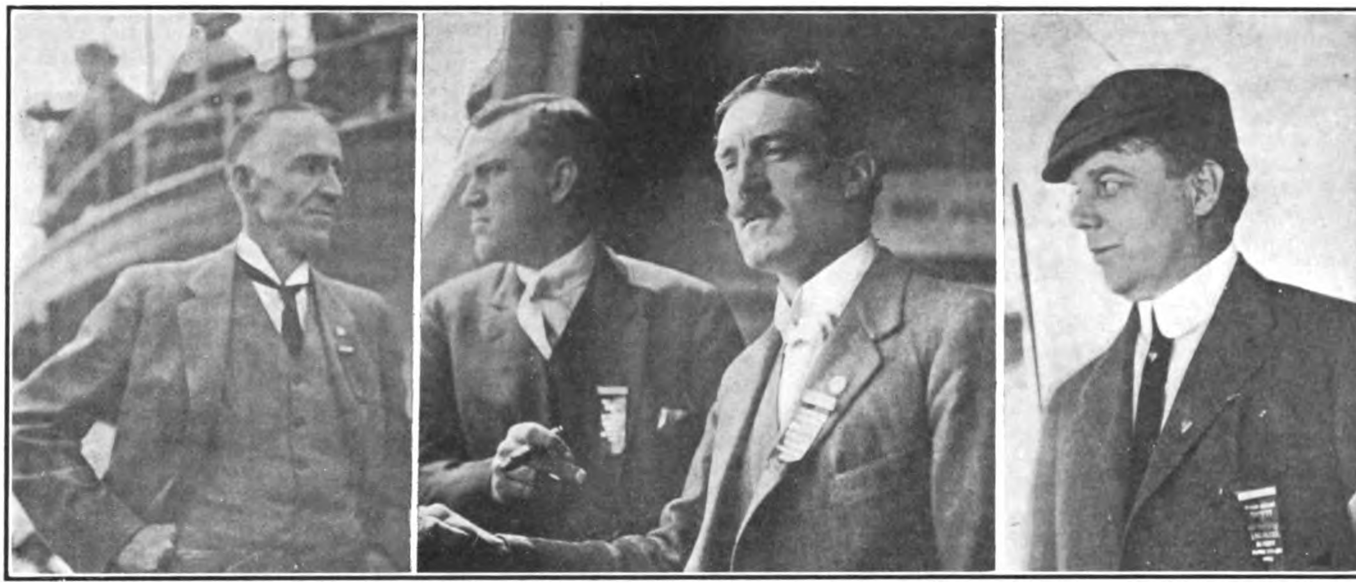
Howard Marmon, Nordyke & Marmon—I have nothing of moment to add. The thought has been broadcast in many minds that the standardization work of the society has been designed to usurp the work of the factory engineer whereas it has solely been intended to facilitate it.

L. J. Flint, Grip-Nut Company—I should like to know what has been done in the matter of bolts and nuts. The Society of Mechanical Engineers has never been able to decide the question of standard weight of bolts and nuts, and I think it would be well if the miscellaneous sub-committee of the standard committee would take this matter up; it would greatly facilitate much work to have these weights standardized.

Clarence E. Whitney, Whitney Manufacturing Company—I am in full appreciation of all the work that the standards committee has done. The company I represent has already saved many dollars by working toward the standardized sizes set by the society.

Howard Coffin, Hudson Motor Car Company—I would like to add one thought: In all activities we must have conservatives and anarchists. We will have suggestions sent in for standardization work which are absolutely foolish, as an example, the standardization of threads for hub caps has been suggested and it was immediately decided that such was too much a matter of detail and the subject was dismissed. The real energies of the standards committee will be exercised along sane lines and for the general good. Often the various standard sub-committee will send out letters containing foolish suggestions for standardization work. The committee knows them to be foolish, but it feels called upon to leave the disposition of them to the entire committee.

H. W. A. Brewer, London, Eng.—One of the points which has interested me most is the business way in which the affairs of your society are conducted. For many years our engineering associations in England have been attempting to standardize work, but to date I have not received any information as to what they are actually accomplishing. I have shown the data sheets issued by your society to English engineers and they are absolutely surprised at the amazing progress you have made here. I think that for a go-ahead nation and a society of such that you mix up dimensions a little; for example, I



F. H. Floyd defiant H. L. Pope annoyed E. W. A. Brewer perplexed Clarence E. Whiting amused

note on some of your sheets some of the dimensions are given in decimals expressed in thousandths of an inch and in another place you express dimensions in sixty-fourths of an inch. This is bad. Further, in going through your standard reports there are certain search-light paragraphs which it would be well to print on small cards for general distribution to the industry. For example:

"Standardization is the last word in a practice.

"Standardization has no regard to materials used but only to shapes and sizes."

I am particularly interested in the standardization of fittings for carbureter attachments and connections. We in England import many American cars and our motorists are very particular in the matter of cost of gasoline and also tire cost. We often want to change carbureters, and as it now is, it costs as much to install the new carbureter as the carbureter costs. This is due to the new manifolds and new gasoline and water-pipe attachments needed. In addition the car owner loses a week's use of his car while the work is being done.

David Fergusson, Pierce-Arrow Motor Company—There is absolutely not any criticism to make on the work of standardization as outlined by Chairman Souther. There is a little criticism on certain points that certain sub-committees of the standards committee may take up with the object of standardizing. One thing of this nature is the absurdity of trying to standardize truck speed. Placing a maximum speed of 8.5 miles on a 5-ton truck is absurd, as the Pierce truck is made for 13 miles per hour. I think that there are many lines in which a speed of 8.5 miles per hour will not pay. In the matter of tire sizes and wheel dimensions the committee has done good work, but there seems to be something wrong in the way the work has been carried out. On our truck we have adopted the Goodrich tire and we have to put a metal band over the wheel in order to accommodate the tire, which is not an S.A.E. standard tire size.

President Donaldson informed Mr. Fergusson that the truck speeds referred to were not S.A.E. recommendations, but merely the desires of makers as taken by a straw vote, and, further, that the National Association of Automobile Manufacturers had adopted a schedule of truck speeds which were lower than these mentioned.

Kennedy Discusses Truck Work

W. P. Kennedy, New York—Regarding standard sizes of truck wheels and tires, I want to corroborate President Donaldson as to proper truck speeds, as the truck committee has not made any recommendations on this question. The committee on wheel dimensions and tire fastenings for trucks has nothing to do on tire sizes. Our work was to standardize wheels and our recommendations ended with a definite idea on felloe bands as recommended by wheel makers. Before our recommendations wheel makers had to carry in stock months before they got their orders vast quantities of materials amounting to many thousands of dollars, but with the standardizing of sizes this money was put into other uses. Today nearly all of the tire makers for commercial motor vehicles are working to S. A. E. standards.

D. F. Graham, Bower Roller Bearing Company—Regarding the bearing division of the standards work much can be said. The work of this committee has benefited the makers of bearings and also the makers of cars in that it is very much easier for the bearing makers to get together in regard to tolerances allowed as to just how much the bearing shall vary from the standard one way or the other. The amount of variance permissible in housings for containing bearings has certainly been simplified.

J. G. Perrin, Lozier Motor Company—We are all impressed with the possibilities and impossibilities of standardization. The change of name from Standard to Recommended Practice will aid in the movement and broaden the scope of the work. I think a great deal of good has been accomplished. In many fields the standardization work has quickened competition. An example: A popular maker of magneto or carbureter uses many unstandard sizes and so it is almost impossible for the maker to attach another make because of these sizes, but when all parts are made to standard sizes it will not be much of a task to substitute any make for any other make of part.

Wall Ventures a Suggestion

William G. Wall, National Motor Vehicle Company—We use many standard parts. I have always been a believer in the standardization work of the S.A.E. I have one suggestion, namely, in the matter of standardized yokes and rod ends. This work was taken over bodily from the Association of Licensed Automobile Manufacturers and these standards were set four or five years ago. Our ideas of wearing surfaces have changed since then and it may be these should be changed.

Regarding Mr. Wall's communication concerning yokes and rod ends, President Donaldson explained that the society had taken over the work of the A.L.A.M. and that the A.L.A.M. had issued one set of standards years ago which were revised before being handed over to the S.A.E. and that since taking them over, the standards committee has revised them twice.

C. T. Meyers, General Motors Company.—I have had to do only with truck construction and in nearly every case we have adopted or arranged to adopt S.A.E. standards and in all new designs we are laying down we are working to S.A.E. standards. It is very important in truck manufacture to use standard parts as spare parts must be carried in stock in the branch houses and agencies all over the country.

H. L. Pope Manufacturing Company—The work of the standardization committee should be highly complimented. In our legal courts we fight for years on matters in litigation and often previous decisions are reversed and so we should not be surprised at sharp contests in this work. If I have troubles with working any standard part into a car I generally find two or three ways out of the difficulty, and where any engineer cannot follow the work he can write to the committee.

C. R. Watson, Cadillac Motor Car Company—My views of the questions of standardization are different from many others. I work for a concern that gets vast benefits from standardization work. The internal standardization work of a car building concern is important, where all parts of the motor must fit perfectly, the piston, the cylinder, etc. In such a car there is a benefit to every owner. How does the world-wide garage man receive such standardization? He wants to carry the smallest stock of spare parts possible and when a car comes in for repairs he wants to make the quickest possible repair. He wants to do that work without needless expert repairmen. If the parts are all of standard size this can be done, if not he needs expert help, which costs much, the car owner paying the bill.

Steinmetz Favors Standardization

J. A. Steinmetz, Janney, Steinmetz & Company—We make seamless steel gasoline tanks and standardization aids very much. We make standard diameter tanks and a change of 1-16 inch in diameter from these standards costs the automobile maker perhaps $1,500 to $2,000 a year. We require dies for our work and the more dies the more cost. Within the last two years we have changed 50 car makers over to standard sizes and saved each over $3,000 per year. We have also come to use the standard iron pipe size of tank fillers and caps, caps for you which you can purchase at a small price all over the country instead of using the high-priced heavy brass caps of non-standard size and which are so difficult to secure.

L. S. Bowers, Schwarz Wheel Company—I speak as a wheel maker. We are vitally concerned in the development of these standards. Before the adoption of standard wheel dimensions for trucks it was impossible to make up any stock for customers as nothing could be done until the customer's specifications were in. Since the adoption of the wheel standards we can make up felloes long in advance and can also carry truck wheel bands and so are in a position to give quick delivery. The standards mean economy to maker and owner. It was my understanding the tire makers would all come to making standard sized truck tires and we should all get after them.

Chairman F. E Moscovics, of a special advisory committee on magneto standardization, read the report of a meeting held in Indianapolis May 31, 1912, in which 95 per cent. of the magneto manufacturing interests were represented. The report showed that the magneto makers agreed that standardizing the following named magneto parts should be taken up and considered by the standardization committee: Shafts; base height; location of studs, or holes, in relation to the key point on shaft; overall dimensions; length of advance lever and the standardization of holes in the advance mechanism, and the relation of keyway setting in armature shaft to the moment of break in the breaker mechanism.

Recommendations of the Committee

The committee recommended adoption of a standard taper shaft for four and six-cylinder magnetos. The length of the taper was put at .5905 inch; the large diameter of the shaft at .5905 inch; the angle of taper 5 degrees and 45 minutes, and the small diameter of the shaft .472 inch. To be furnished with No. 3 Woodruff key.

Further recommendations of the committee were: First—The adoption of a thread for the end of the magneto shaft of 3.8, 16 threads U.S.F., the length of the thread to be .5905 inch. Second—That in the base height the distance from the center of the armature shaft to the base be 1.771 inch or 45 millimeters. Third—That for two-magnet machines there be used from the center of the first bolt hole to the large end of the taper a dimension of 2.086 inches. Fourth—That the size of the hole on a two-magnet machine be 3-8, 16 threads U.S.F. Fifth—That owing to the declining business in three-magnet machines no cognizance be taken of standardizing those parts and that manufacturers requiring those instruments for special purposes or on exceptionally large motors can very handily obtain the information by writing to the different magneto manufacturers. Sixth—That engineers allow a sheer clearance of 8 inches from base height to top of magneto space, a width of 5 inches and an overall length of 10 inches. Seventh—That magneto advance-levers have a radius of 2 1-8 inches from the center of the armature shaft and that this hole be drilled to take a tapping hole for 1-4, 28 x pitch thread. Eighth—That the committee recommend that the keyway of the armature shaft should bear a definite relation to the moment of break in the breaker box, when the breaker box is in the full retard position.

Legal News of the Week

Michigan Supreme Court Reverses Finding of Lower Tribunal in Case Involving Handling an Agency

Wants a Receiver for Motor Starting Company—Court Upholds Gordon Trademark

DETROIT, MICH., July 1—Reversing the Wayne County Circuit Court, the Supreme Court recently held that the verdict rendered below in favor of William G. Isbell, former representative of the Anderson Electric Car Company, for $23,000 for damages by reason of the cancellation of the agency is null and void.

An original contract between the litigants called for the maintenance of a suitable garage for handling automobiles, together with such appurtenances as are usually required in such a business. An auxiliary agreement made soon after the original contract provided for allowing Isbell to place gasoline cars in the garage, as well as those of the electric type, until such time as the business in the latter should have developed to a point where the caring for them offered a sufficient business to warrant their care exclusively.

The Anderson Company later notified Isbell that he was not caring for the business properly; did not advertise sufficiently; did not provide proper labor for caring for the business, and was not carrying any of the cars in stock. The result was the cancellation of the agreement.

Isbell brought suit and was awarded $23,000 damages in the lower court. The appeal to the higher tribunal, however, brought a reversal.

Marking Out the Scope of Agency

That an action by a principal for money had and received is appropriate to recover profits from an agent who, contrary to his agreement to sell certain goods of the plaintiff company exclusively, broke his agreement and sold a similar line of goods in competition with that of his principal, was held recently in the case of Robert Reis & Company against John E. Volck by the Appellate Division of the New York Supreme Court.

While no patent rights were involved in this dispute, the general rule laid down by the court proves interesting and important to the automobile trade.

In lay terms the court holds that where an agent contracts to sell a certain line of goods exclusively and violates his agreement, becoming a competitor of his principal, a suit by the principal will lie to recover the profits made by the agent through the unfair competition inaugurated by him.

Ask Receiver for Starter Company

INDIANAPOLIS, IND., June 29—Suit has been brought in the superior court at Indianapolis by the Indianapolis Light and Heat Company asking that a receiver be appointed for the Motor Starting Company. The suit was brought on an account of $116 for electric current, and it is charged the concern, which has been manufacturing a motor-starting device, is insolvent. Lew W. Cooper, formerly president of the board of public safety, is president of the company.

Cut-Out Law in Effect July 16

July 16 is the date upon which the new muffler cut-out ordinance goes into effect in New York. The investigation of the subject of cut-outs and their relation to lost power, upon which the metropolitan lawmakers relied for some of the data presented before that body, was undertaken by the Touring Club of America and showed that the cut-out added only a small fraction to the power of the motor, while the noise resulting from running without the muffler proved sufficiently annoying to a large number of citizens to raise a prejudice in their minds as to automobiling in general.

The movement culminated in the following ordinance, which was duly endorsed by the aldermen:

Section 1. Every motor vehicle propelled by an internal combustion engine, when such vehicle is on any street, road, avenue, alley, park, parkway or public place within the city limits shall, when such engine is running, be equipped with a muffler or silencer, through which all of the exhaust gases from the engine will escape into the atmosphere.

Section 2. It shall be unlawful for the operator or driver of any motor vehicle to use any cut-out, fitting or other apparatus, or a device which will allow the exhaust gases to escape into the atmosphere without passing through a suitable muffler or silencer as described in Section 1.

Section 3. Any person violating the provision of this ordinance may, upon the conviction thereof by any city magistrate, be fined a sum not exceeding $10, and in default of payment of such fine may be committed to prison by such city magistrate until the same be paid, but such imprisonment shall not exceed 10 days.

Gordon Trademark Is Upheld

CHICAGO, ILL., July 1—Suit of the Vehicle Apron & Hood Company against the American Tire & Rubber Company, based upon alleged unfair competition of the defendant company in substituting other tire covers when the Gordon tire cover of the complainant was named by purchasers, has been decided in favor of the complainant.

Judge Kohlsaat of the United States District Court has signed a decree perpetually enjoining the defendant from such practices and from the use of the trademark name, Gordon, in connection with any other than such tire covers. The defendant is ordered to pay the costs of action.

Makes Car "Borrowing" a Felony

The assistant United States attorney says the Government is planning to co-operate with the police and court in stamping out if possible the practice, now almost of daily occurrence, of taking motor cars and, after using them for joy rides, abandoning them. A special law to cover cases in which the grand larceny charge would not hold, where motor cars are taken without right, will be asked of Congress. A bill framed with the co-operation of the United States attorney's office will be presented to Congress at an early date.

Enjoins Individuals, but Not Union

BUFFALO N. Y., July 2—Judge Hazel in United States District Court has fined Charles Stemp, Andy Smith and William Hopkins, $100 each for violating a federal injunction restraining them from interfering with the strike breakers in the plant of the Aluminum Castings Company, Elmwood Avenue, which concern makes aluminum castings for automobiles. Judge Hazel denied the motion of the Aluminum Castings Company to make permanent the injunction against the molders' union, but the injunction against the individual striking molders, however, is continued. The penalized men are being held until the fines have been paid.

Defends Quebec's License Law

MONTREAL, June 25—"The province is licensing chauffeurs and not engineers," said Wallace Dawson, collector of provincial revenue, who has charge of the issuing of licenses, when questioned regarding the comments on the government's method of examination made by a local association of chauffeurs. "The province requires that a man be competent to conduct a machine, and not to manufacture. The question as to hair, eyes, etc., serves a twofold purpose—in case of an accident to identify the chauffeur and to prevent a transfer of licenses. Every chauffeur must carry his license with him, and the description must tally with the person who holds the same. Have you served in a penitentiary? is a query as to whether the applicant has been convicted under traffic law in any country. The query as to occupation is to establish whether or not the applicant is to act in capacity of operator or chauffeur.

"The mechanical end is taken care of," said Mr. Dawson, "in that an applicant must have three witnesses over 25 years old who swear under oath that they are personally acquainted with him; how long they have known him; that they believe his statements as to knowledge of the machine to be true; that the applicant is not in any way, physically or mentally, incapable of handling a motor vehicle, and that they believe him to be competent, and the applicant is required to state under oath the power of vehicle previously operated and the number of miles run."

Western Transferred to Rutenber

CHICAGO, July 2—The incorporation of the Rutenber Motor Company for $1,350,000 in Delaware last week was the forerunner of an important change in the Western Motor Company, of Marion, Ind., which long has manufactured Rutenber motors, in that it marks the transfer of the business of the Western Motor Company to the newly organized Rutenber Motor Company and the infusion of new financial blood in the shape of George W. Bowen, of Auburn, N. Y., president of the Bowen Manufacturing Company, of that city, maker of grease cups and other oiling devices.

Confirmation of this fact was secured today from J. W. Stephenson, general manager of the Western Motor Company at Marion. While the deal has not been finally completed, it is as good as made, Mr. Stephenson says, and Mr. Bowen will be heavily interested from a financial standpoint. The name of the company will be changed to the Rutenber Motor Company and Mr. Stephenson will remain as general manager and a large stockholder. With the new capital interested it is planned to double and probably triple the capacity of the engine plant at Marion.

Innocent Driver Fined for Fake Tag

ALBANY, N. Y., July 2—Because he used a license plate on the rear of his automobile which had not been issued by the Secretary of State, Charles A. Wetmore, representative of a local automobile agency, was arrested Saturday on complaint of Gustave Semmig, inspector in the automobile bureau of Secretary Lazansky's office. It is claimed that the license plate on Wetmore's car was of cardboard, and that the size and also the color of the figures was similar to that of the official license plates. Wetmore pleaded that he knew nothing of the plate being a fake, as he had simply driven the car from the garage on a test trip, and although Justice Brady accepted the explanation, he fined the violator $5 as a matter of principle.

Atlas Engine in Receiver's Hands

INDIANAPOLIS, IND., July 2—Fred C. Gardner has been appointed receiver for the Atlas Engine Works, American manufacturing licensee under the patents of Charles Y. Knight covering the Knight sleeve valve automobile motor. This action was precipitated by the filing of suit against the Atlas company involving the payment of a claim for $2,387. Judge Weir, of the Superior Court, entertained an application for a receiver made by F. H. Wheeler and George M. Schebler. Bond in the sum of $50,000 was filed and the business will be continued.

Officers of the Atlas company have announced that the cause of difficulty lies in the fact that the largest customer of the company has suspended payment temporarily, owing the company about $100,000. At the same time, according to the announcement, a request has been made by this customer to suspend indefinitely all deliveries under the contracts existing between the Atlas company and the customer.

Covers Moving Cars Only

Milwaukee's Universal Light Law Applies To Cars Which Are in Actual Operation

New York State Examiner Would Confine Licenses to Those Only Who Show Ability

MILWAUKEE, WIS., July 1—The universal light ordinance proposed for the city by the Milwaukee Automobile Club, and recommended for adoption by the committee on judiciary, has been amended to apply only to moving vehicles, as there is at present an ordinance in Milwaukee which provides that any vehicle left standing on a street or in an alley must be marked by at least one light visible in both directions. The club endeavored to have its ordinance passed, and the old ordinance abolished, to avoid superfluity and make the ordinances relating to the subject more compact. However, there was danger of losing both ordinances, so the club decided to let well enough alone and have two ordinances to cover the ground which one good statute would cover. The M. A. C., acting with the Wisconsin State A. A., will endeavor to push a universal light law through the next session of the Wisconsin Legislature, convening in January, 1913.

Body Company Suspends Operations

FLINT, MICH., July 1—Following an order made in the United States Court in Bay City, the Flint Body Company has closed its doors. Action in the court was taken by creditors of the concern. An inventory will be taken and the future of the company decided. Robert H. Cook, who was vice-president and secretary of the company, has been chosen by the creditors as receiver. The company was incorporated January 1, 1909, and capitalized at $50,000. William E. Stewart, president and treasurer of the company, was principal stockholder.

No License Unless Competent

ROCHESTER, N. Y., July 2—That every man or woman who drives an automobile in New York State eventually will have to pass a road examination and show a certificate to the effect that the bearer is competent to operate a machine, is the belief of R. H. Strickland, Rochester, state examiner of chauffeurs, who is examining applications for licenses in various cities. He declares that automobiles are being driven by incompetent people without the slightest regard for existing laws concerning the running of these machines. Mr. Strickland, whose headquarters is in Buffalo, declares new owners ought to be required to give demonstrations of their competency in driving automobiles before being provided with a license.

Grossman to Appeal Decision

Formal order has been issued by Judge Hand of the United States District Court, allowing Emil Grossman, nominal defendant in the recent suit of J. H. Sager, involving patent rights on automobile bumper manufacture, to perfect an appeal from the decision of Judge Hough which sustained the Sager patent.

The opinion of Judge Hough was couched in doubtful terms, but the decree granted provided for a permanent injunction and it is from that order that the Grossman party takes appeal. The case in due course will be presented before the United States Circuit Court of Appeals. The actual defendant in the case is the United States Bumper Company of Chicago.

Willys Acquires Garford

Overland Company Purchases Common Stock of Elyria Concern, Which Will Be Operated at Full Capacity

General Vehicle Company Contracts to Build Daimler Trucks in This Country

TOLEDO, O., June 28—Announcement has been made that President John N. Willys, of the Willys-Overland Company, today consummated a deal by which he purchased the common stock of the Garford Automobile Company, of Elyria, O. There is $2,000,000 worth of the stock and the product will be handled through the Toledo sales department of the Willys-Overland Company. The Garford plant in Elyria is capable of employing 3,000 men and the concern makes a high-class six-cylinder passenger car and 2, 3, 4, 5 and 6-ton automobile trucks. With this plant the Willys-Overland Company will make all classes of cars from a low-priced $900 car to the high-priced touring car and automobile trucks. The Elyria plant will in the future be operated at its full capacity. Mr. Willys now controls not only the Overland business in Toledo, but the Gramm Motor Truck Company at Lima, O., the Auto-Parts Company, at Elyria, N. Y., and the Garford Company. They will all become part of the proposed $15,000,000 corporation which will be organized as soon as the secretary of state authorizes the increase in capital stock, application for which will be filed within a few days.

Enormous improvements are planned for the local plant of the Willys-Overland Company, and of the Kinsey Manufacturing Company, both of which concerns will be doubled in capacity. It is expected to turn out 40,000 cars from the local factory during 1913. According to a statement made by a member of the Overland Company, orders for from 2,000 to 3,000 cars have been turned down within the past 6 weeks because of inability to turn them out.

Crude Rubber Market Is Firm

A firmer tone was apparent in the crude rubber markets of the world during the past week. Trade in New York has been of small proportions and most of it was for prompt delivery. A slight hardening of prices was felt and the current level is on a basis of $1.12 1-2 for up-river fine. At the London fortnightly auction, which is scheduled for the first and third Tuesdays of each month, the offerings include 580 tons of plantations.

Barnes Resigns from M. & A. M.

Claire L. Barnes, third vice-president and member of the board of directors of the Motor and Accessory Manufacturers, has resigned owing to a series of shifts in the membership in the association. William H. Crosby of Buffalo was chosen to fill out the unexpired term of Mr. Barnes as director until January 1, 1914.

The following concerns were elected to membership in the organization: Hood Rubber Company, Boston, Mass.; The Lefever Arms Company, transmissions and jackshafts, Syracuse, N. Y., and The American Hardware Corporation, Corbin Screw Corporation, speedometers, New Britain, Conn.

G. V. to Make Daimler Trucks

James M. Carples, general manager of the Daimler Import Company, has made the following announcement:

"Contracts have been signed between the Daimler Manufacturing Company, the General Vehicle Company and the Daimler Motoren Gesellschaft, Germany, for the future manufacture in America by the General Vehicle Company of all the types of commercial vehicles made by our factories in Germany.

"Representatives of the General Vehicle Company have been abroad for the last three months negotiating and carefully looking into this matter.

"As far as the Daimler Import Company is concerned, we shall continue to import both the Mercedes pleasure and commercial vehicles the same as before. Our manufacturing rights for the pleasure vehicle in America have not yet been definitely concluded but negotiations are well under way and I believe that upon the arrival next month of our directors I shall be able to inform you that this has been accomplished and that the Mercedes pleasure car will hereafter be manufactured in America by a syndicate as well known and as well equipped for this purpose as the General Vehicle Company is to make a success of the Mercedes commercial vehicle."

Combine Business with Pleasure

Instead of holding regular meetings in July and August, the National Association of Automobile Manufacturers will combine the two meetings and hold the joint session at Christmas Cove, Me., the summer home of Samuel A. Miles, general manager of the organization. The meeting is scheduled for July 30.

Overland Stocks on 'Change

Application has been made by the Willys-Overland Company to list its stock issues on the New York Stock Exchange and it is understood that such action will be taken. The tradable total includes at least $15,000,000 of securities under the recently authorized increase in capitalization.

Market Changes of the Week

The rise in steel, which began last week, continued, so that now most of the leading makers charge the prices given in the tabulation below. Beams and channels, following the trend of other products, advanced $1 a ton. The activity in steel which has been witnessed by the past few months, continued during the week. Copper presented a restrained situation, so far as dealings in the metal were concerned, while copper securities were subject to considerable changes in the stock market. The air of speculation which has surrounded this commodity, has not as yet been dispersed. Tin and lead experienced a week of moderate activity with insignificant changes.

Gasoline advanced to 20 cents a gallon in 200-gallon lots, which gives a total rise of 6 cents for this fuel since the beginning of the year. At the same time Pennsylvania and Kansas crude remained unchanged. The range of prices follows:

Material	Wed.	Thurs.	Fri.	Sat.	Mon.	Week's Change
Antimony, per lb.	.07	.07	.07	.07	.07	....
Beams and Channels, 100 lb.	1.41½	1.41½	1.41½	1.41½	1.41½	....

Big Increase in Exports

As Compared With May, 1911, Value of Automobiles and Parts Shipped Abroad Almost Doubled

Slight Increase in Imports—Ascribe Slump in Millinery Trade to Automobiles

WASHINGTON, D. C., July 1—The value of automobiles and parts exported from tne United States during May, 1912, was almost double that exported during May, 1911. Canada, as usual, bought almost half of the exports sent abroad by this country, the total for May, 1912, having been $1,352,856. This was an increase of $245,751 over the corresponding month of last year. The exports to the United Kingdom, it is noted, were more than double those of May, 1911.

Probably the most remarkable increase of all, though, was in the exports to British Oceania, which were but $109,813 in May of last year, and jumped to $412,565 in May of this year. Asia and Oceania also showed a big increase, the exports growing from $61,765 in May last year to $149,309 in May this year.

The most interesting figures, however, are in comparison of the totals for the 11 months ending May, 1910, 1911 and 1912 respectively. These show that the 1912 figures are approximately two and one-half times those of 1910, and more than $9,000,000 in excess of those of 1911. The proportion of increase of 1912 over 1911 is about twice that of 1911 over 1910.

The imports for the same period covered by the report of exports show a slight increase as between May, 1911, and May, 1912. The imports from France and Italy show an increase, by comparison, but those from the other countries show a falling off. The tables follow:

COMPARATIVE EXPORTS OF AUTOMOBILES AND PARTS FOR MAY, 1911 AND 1912

	1911		1912	
	Number	Value	Number	Value
Automobiles, and parts of—Automobiles	1,466	$1,513,547	3,009	$2,963,818

Automobile Securities Quotations

In the list of automobile securities the stock changes for the past week did not develop anything startling. The waiting attitude noted during the week previous was if anything more pronounced than ever. This condition kept the investment issues extremely solid but naturally developed a slight drop in the speculative shares, with, however, a few exceptions where a 1-2 point rise was noted. The asking price in the gilt-edged issues still shows no tendency in falling off, indicating a substantial condition in these shares and an encouraging condition of the industry. The following table shows the comparison of this year's prices with those of 1911 at the corresponding time:

	1911		1912

Big Addition to Morrow Plant

ELMIRA, N. Y., July 2—A mammoth addition to the already large plant of the Morrow Manufacturing Company, South Main and Scott streets, was opened today with the employment of 300 additional skilled mechanics. This company manufactures transmissions and small parts for Overland automobiles for the Willys-Overland Companies at Indianapolis and Toledo, O. Before the new addition was opened for business the concern turned out an average of 130 transmissions daily, and with the additional workmen and the annex to the large factory it is proposed to manufacture at least 200 transmissions every day solely for Overland cars. At least 70,000 pieces for automobiles are made daily, totaling 16,998 pounds of finished material. The work is mostly done with automatic screw machinery and each separate piece must be carefully inspected before shipment is made. Besides spending $1,000 weekly for materials as lumber, hardware, etc., for use in the plant, the weekly payroll of this concern totals $10,000 without including foremen, office men or officials.

Company to Make Martin Tractor

INDIANAPOLIS, IND., July 2—The Martin Tractor Company has been organized and incorporated with an authorized capital stock of $50,000 to manufacture the Martin Tractor in this city. The incorporators include: Charles H. Martin, Hugh R. Richards, F. B. Davenport, Edward D. Moon and George D. Thornton.

Automobile Hurts Millinery Trade

LOUISVILLE, KY., June 29—The modern motor car, with its attendant veil, donned by women autoists, because of damage the wind does to hats, is responsible for the falling off of trade in the millinery line, according to A. O. Niedlander, of Indianapolis, president of the Millinery Traveling Men's Association. The statement was incorporated in the annual report of the president of the association, which was read at the opening session of the convention at the Hotel Henry Watterson this week.

Detroit's Building Boom

Many Companies Putting Up New Structure and Additions to Present Ones —Tire Exports Increase

Horace DeLisser With Ajax Rubber Company—Carter Corporation Plant Sold

DETROIT, MICH., July 1—After a comparative lull in factory expansion locally, building operations seem to have been resumed this summer on a comparatively large scale. The largest addition of which formal announcement has yet been made, is that of the Chalmers Motor Company, which has authorized and will immediately begin construction of a new factory building, adjoining its present plant. The building will be four stories in height, conforming in materials and general design to the buildings already in use by the company. The length will be 191 and the width 71 feet. In the neighborhood of 55,000 square feet of floor space will be added to the plant. Arrangement is also being made by the Chalmers Company to still further increase its facilities by the erection of another building, also four stories high, and 400 by 60 feet. This will be practically a duplicate of the two main buildings of the present plant, each of which conforms to this size. The Chalmers Company has more than 30 acres of room and has ample chance for expansion.

Building operations will, it is understood, soon be begun by the Cadillac Company, which has been severely cramped for room during the past two seasons and is at present using an immense tent near its plant. No definite announcement has yet been forthcoming, however.

The Briggs-Detroiter Company has authorized a large addition to its plant north of Detroit, on the line of the Grand Trunk & Michigan Central, Bay City division. This company is one of the most prosperous of the smaller local factories and has been absolutely unable to fill its orders during the season, which is its first. The new addition will almost double the capacity of the plant.

Building operations are also in progress at the Studebaker, Ford and Packard plants. This, however, is a normal condition, as the occasions have been rare in the history of these three companies when expansion of some sort was not in progress.

Another firm which is adding materially to its facilities is the Poss Motor Truck Company. This is by means of a change of base, however. Up to date the Poss has been manufacturing in the old Anhut plant on Abbott street. The company has now purchased the plant formerly known as Brush Runabout No. 2, at Euclid avenue and the Grank Trunk tracks, in the northern part of the city. Considerably more room is thus placed at the command of the company, which is understood to be very well backed financially and has been manufacturing on an increased scale of late.

La France Aerial Truck Tested

ELMIRA, N. Y., July 2—Fire Chief E. H. Price of the Flint, Mich., fire department, accompanied by B. Brumph, C. R. Matt, L. D. Lane, George Norwood, Charles Willis, and Thomas R. Johnson, of Chicago, district sales manager of the American-LaFrance Fire Engine Company of this city, witnessed here last Friday a demonstration of the first motorized aerial fire truck made by the local concern. This truck was made for Elizabeth, N. J., fire department and has attracted widespread attention. Flint, Mich., wants one, and the test given the truck proved highly successful. The aerial truck has a wheelbase of 340 inches and the driving apparatus is applied to every wheel of the machine. The gasoline motor is connected with a generator which in turn generates power which is applied through flexible cables to each wheel, which is steerable. This enables the apparatus to carry a huge extension ladder raised by its own power.

The Elmira motorized fire department, including an American-LaFrance Company's motor driven service cart and combination service truck, motor driven, with an extension, spring raised ladder, gave an exhibition run last week, when the Knights Templar convened here, which was highly satisfactory. An alarm of fire was turned in and the motor apparatus responded speedily.

Los Angeles Christens New Car

LOS ANGELES, June 29—"I christen thee 'Perfex' and welcome thee and thy builders into the fold of the many industrial institutions that now grace our fair southland." With these words, H. B. Gurley, assistant secretary of the Los Angeles Chamber of Commerce, broke a bottle of Owens River water over the radiator of the newest automobile to make its advent into Southern California.

The new car is built in Los Angeles and therefore the welcoming ceremonies. The machine was designed and built by James Fouch in his new plant in Los Angeles. Several wealthy Easterners are interested in the Perfex Company, among them Paul Brown, a broker and member of the New York Stock Exchange.

Tire Exports Increase $500,000

WASHINGTON, D. C., June 29—The exports of motor car tires in May last were valued at $272,346, as against a value of $310,346 in June a year ago. However, during the 11 months' period ended May the exports increased in value from $1,838,482 in 1911 to $2,335,920 in 1912.

The imports of India rubber in May last amounted to 9,802,830 pounds, valued at $8,918,506, as against 6,399,946 pounds, valued at $6,340,948 imported in May a year ago. The imports for the 11 months' period increased from 65,723,492 pounds, valued at $70,736,522 in 1911 to 103,395,020 pounds, valued at $87,570,396 in 1912.

De Lisser Goes Back to Tires

Announcement was made Friday that Horace De Lisser has resigned as vice-president of the United States Motor Company, to take up the chairmanship of the board of directors of the Ajax-Grieb Rubber Company, makers of Ajax tires. Mr. De Lisser had been with the United States Motor Company since its organization, leaving the tire business to join with Benjamin Briscoe in that enterprise.

The Ajax company now plans the establishment of a tire factory abroad which will produce tires for Europe and parts of the world not easily served from the factory at Trenton, N. J.

Mr. De Lisser will leave for Europe on the Kaiser Wilhelm der Grosse, on July 30, to be gone six or eight weeks.

Carter Corporation Plant Sold

WASHINGTON, D. C., June 29—The plant of the Carter Motor Car Corporation, at Hyattsville, Md., was sold at auction this week and was bid in for $12,000 by P. M. Galvin, acting for the Independence Motor Company. It is understood this action was taken to protect the stockholders of the defunct corporation. It is planned to organize a new directorate of the Independence Company and resume operations.

June's Big Motor Incorporations

Automobile incorporations formed during June and having a capitalization of $1,000,000 or more are as follows: Delaware—Amplex Motor Car Company, $1,000,000; Rutenber Motor Company, $1,350,000. Maine: Edwards Motor Car Company, $2,000,000. Total, $4,350,000.

Among the manufacturers of automobiles and accessories and sales organizations connected with the trade the following incorporations of $100,000 or more have been filed during the month: New York: Brooks Motor Car Company, $100,000; Knickerbocker Commercial Vehicle Company, $300,000; Robert Stock Auto Spring Tire Company, $300,000; Resilient Punctureless Tire Company, $100,000, and the Weitch Motor Manufacturing Company, $200,000. New Jersey: National Automobile Sales Company, $300,000; Newark Auto Truck Manufacturing Company, $500,000. Massachusetts: V-C Motor Truck Company, $100,000, and Westfield Motor Truck Company, $100,000. Illinois: Cotta Gear Manufacturing Company, $100,000. Ohio: Ideal Commercial Car Company, $200,000. Indiana: Nelson Motors Company, $200,000. West Virginia: Pitt Motor Truck Company, $200,000. Making a total of $2,700,000, or a grand total for the month of $7,050,000.

Denniston Plant Sold for $9,050

BUFFALO, N. Y., July 2—The hearing in the Denniston Company bankruptcy proceedings held here last week resulted in the sale of the company's property to Dr. Edward J. Meyer, 1312 Main Street, for $9,050. The bankruptcy petition indicates that liabilities amounted to $85,745.94, of which $60,385.38 were unsecured. Its assets were $99,636.27, stock being $5,089.43, machinery, $19,219.42, and open accounts $13,727.17. A final hearing in the company's affairs has been set for Wednesday, July 10.

Citizens Want Gift Plant Returned

SHELBYVILLE, IND., July 1—An effort to take back the land and factory occupied by the Clark Motor Car Company has been started by the Citizens' Industrial Association, which about 2 years ago turned the land and plant over to the company. The association has brought suit to foreclose a mortgage and for liquidated damages, asking $26,000 on the ground that the company has not complied with an agreement to employ 150 persons for a period of 5 years, beginning 90 days after the company began operations. Involuntary bankruptcy proceedings were brought against the company some time ago and the plant was recently reopened after having been closed since February. The involuntary bankruptcy proceedings were settled.

Cole Selling Organization Complete

INDIANAPOLIS, IND., July 1—The Cole Motor Car Company starts today to handle its own sales. According to previous announcement, the Henderson Motor Sales Company, which has handled the marketing of the Cole and allied lines, was absorbed by the manufacturing company. The move is progressive, indicating that the time has now been reached when the factory management believe the line is sufficiently developed to allow it to combine the sales with the manufacturing departments.

Kissel Starts on Its 1913 Cars

HARTFORD, WIS., July 1—The Kissel Motor Car Company has started on its 1913 production after a shut-down of 10 days, during which period inventory was taken, the big plant overhauled and new equipment placed. Work will be started during the next month on a new factory building to supplement two large structures erected during the spring of the year. The average number of employees during the 1911-12 season was in excess of 1,100 and with new buildings and facilities, the pay roll for next season will exceed 1,500. Announcement of the new models will be made within a few weeks. It is stated that no radical changes from the existing Kissel practice will be made in the 1913 cars.

Republic's Capital Boost

Will Increase Stock from $6,000,000 to $10,000,000—Speedwell Planning a New Six-Cylinder Car

Corbin Screw Corporation to Make Speedometers—Lion Company Will Accept Adrian's Offer

YOUNGSTOWN, O., June 30—The directors of Republic Rubber Company on Thursday authorized the calling of a stockholders' meeting to be held early in August for the purpose of increasing the authorized capital of the company from $4,000,000 to $10,000,000. The capital will consist, after the increase, of $6,000,000 common and $4,000,000 preferred stock.

No definite announcement has been made as to amount of the additional capital to be issued this year. It is understood, however, that the steady growth of the company's business will require new capital before another season.

The directors have also authorized the construction of a large modern reclaiming plant, which with the completion of the five-story building now under construction will give considerably greater capacity.

It has been reported that there will be a common stock dividend of some size after the increase of capital has been provided for; but when interviewed President Thomas L. Robinson said no action had been taken in regard to the stock dividend.

Speedwell Planning New Six

Numerous changes and improvements will mark the 1913 line of Speedwell pleasure cars. While no detailed announcement has been made by the Speedwell Motor Car Company, it is pretty definitely understood that the models will include both fours and sixes and that the wheelbase will be materially lengthened.

The working force at the plant is to be increased, according to official word from the factory.

Corbin Enters Speedometer Field

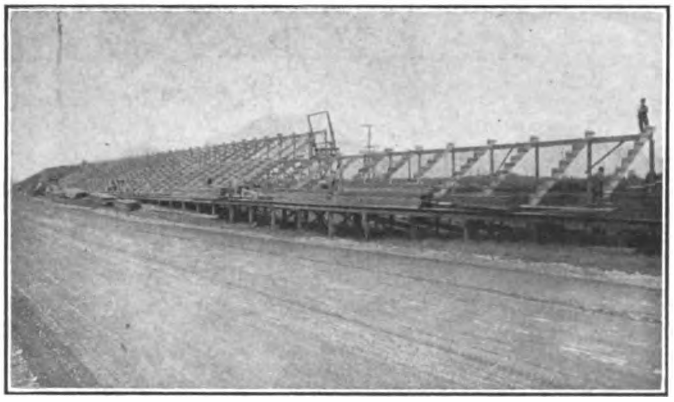
NEW BRITAIN, CONN., July 1—The Corbin Screw Corporation, division of the American Hardware Company of New Britain, Conn., announces that it will manufacture and market the Corbin-Brown Speedometer. The device has heretofore been known as the Brown Speedometer, but under the new name will embody a number of improvements. The Corbin-Brown Speedometer is the invention of Col. W. C. Brown of New York.

Estep Resigns from Packard

DETROIT, MICH., July 1—E. Ralph Estep, advertising manager of the Packard Motor Car Company, has resigned his position and is no longer connected with that company. Mr. Estep has had charge of the Packard advertising, except for two brief intervals, since the early years of the company. He is widely known as an editor and speaker. Mr. Estep's future plans are not announced. As yet there has been no successor appointed at the Packard plant.

Lion Company to Resume at Adrian

ADRIAN, MICH., July 1—Directors of the Lion Motor Car Company, which recently lost its plant here by fire, have decided at a meeting, held in Detroit, to accept the offer of this city of a complete factory building and will equip it as a motor car plant immediately. This plan will enable the Lion people to fulfil their contracts for orders of parts and supplies, already purchased for their 1913 line.



Grand stand at start and finish of Tacoma 5-mile course

Straightaway on Tacoma course before it was ironed out

Ready for Tacoma Races

Seventeen Entries for Two Big Events at 200 and 250 Miles Over 5-Mile Course

Corners Are Well Banked, and Prospects Are Excellent for Fast Time

TACOMA, WASH., June 28—Less than 2 months ago work was commenced on the 5-mile circuit just outside this city upon which the Montamara road races will be run next week. Something like $6,000 has been expended and a marvel has been wrought considering the small amount of time and money that have been available for the purpose. The course is in fine shape today practically throughout its entire length and several of the drivers who will take part in the races have made exceedingly fast time over parts of it.

Part of the course has been laid out over ordinary country highways but quite a material part of the circuit had to be constructed from the grass-roots down. Of course the existing roads that have been included in the course have been revolutionized and the result is to be seen in the broad, safe speedway that has been brought into being by the energy of the road builders.

Right up to the post call the engineers will continue to improve the course. The last of the oiling will be done on Monday but work will continue on the surface until Thursday night. Packers and steam-rollers will not be withdrawn, save for the time allowed for practice work, until sundown on Thursday.

It will take a year before such a course can reach its perfection, but there are many among the automobile enthusiasts here who predict that an average speed of over 70 miles an hour will be attained for the whole of the free-for-all contest. Tetzlaff has said that on the straightaways it is not unlikely that a maximum of 110 miles an hour will be reached by some of the cars.

The course is about 2 miles shorter than the Los Angeles Santa Monica circuit and the straightaways are correspondingly shorter. The turns have all been banked so that there is not one on the course which can not be taken with a fairly wide throttle. It is predicted that 60 miles an hour around any of them will be possible without untoward results.

Work on the grand stands is progressing to completion and accommodations for a vast army of spectators will be provided. The location of the course is just south of the city and can be reached by street car or via the Northern Pacific, which will inaugurate a special service from the center of the town to the grand stand on the race days.

The street car schedule has been extended 1 hour earlier than usual and frequent service will be provided after 5 o'clock in the morning.

Martial law will prevail on the course during both days of racing and the local companies of the National Guard will be on duty to prevent spectators from getting in the way of the racers and to maintain a careful patrol of the whole circuit.

The latest indications are that there will be about twenty entries in the races.

The field now lines up as follows for the two big road races of 200 and 250 miles each, run respectively on Friday and Saturday: 3 Fiats, 1 Benz, 3 Nationals, 2 Coles, 2 Stutz, 2 Mercers, 2 Simplex, 1 Pope, 1 Knox.

Two of the Fiats are 120 horsepower; the third is 70 horsepower; the Benz is 110 horsepower; the Stutz are 50 horsepower, and the others range from 30 to 90 horsepower.

There are still a number of soft and rough spots on the course that are centering the attention of the road makers and so far any supreme speed has not been essayed over it in its entirety. On the straightaways all the contestants have opened wide and several of them have made the whole round in fast time. However, the best mark set in practive to date is a little less than 4:56, which is slightly more than 60 miles an hour on the longest stretch of the circuit. Numerous rounds have been made in 5 minutes and thereabouts.

The fastest spurt indulged in by any of the entries was 1 mile in 41 seconds by the Cooper Stutz.

One reason why rounds have not been made at the 70-mile-an-hour rate is that there is a rough spot across the course 3-4 mile from the end of the best straightaway, necessitating much care and low speed. On this spot a steam-roller and a gang of tampers have been busy for 2 days past and during the practice today the drivers began to shoot their cars across at full speed. Just beyond the last turn before reaching the main stands there are two more bad spots which will be rolled out and resurfaced tomorrow.

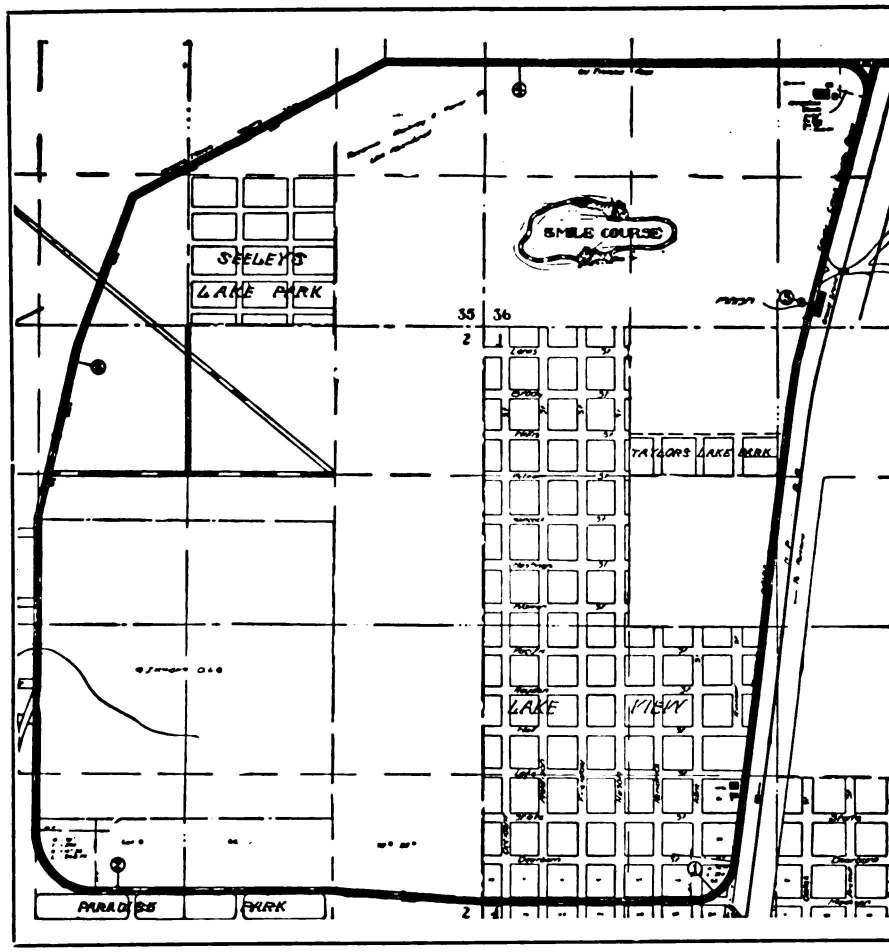
Broad banked turn, near Lakeview, before completion

The three chief corners on the course have turns constructed on a radius of 1,000 feet, which ought to be sufficiently gentle and safe to make the race comparatively free from mishaps. They have been banked according to the most approved formula, and if there should be any spills the management predicts that they will not occur on the turns.

The pits are located above the finishing line and within easy view of all but one of the stands. The seating capacity of the grandstands is well above 20,000, and the parking spaces are sufficiently commodious to take care of 2,500 automobiles.

The prizes offered to the winners are satisfactorily large. In the big free-for-all the money purse amounts to $5,000 and the total amount of prize money hung up is $10,000. These purses with the challenge trophies that they carry make the prize list formidable.

Special arrangements have been made at all the local hotels to take care of the crowds and low excursion rates to this city have been granted by the railroads. While the population within a radius of 50 miles is not up to metropolitan standards and ideas, the territory included is rich from every material viewpoint and its residents are prosperous. In one of the small valleys near Olympia, which is devoted to fruit culture, it is claimed that there are more automobiles owned per capita of population than in any similar sized locality in the world.



Map of the Montamara 5-mile course, near Tacoma, Wash.

Small Crowds at Washington's 2-Day Meet

WASHINGTON, D. C., June 29—Designed to afford some amusement for the big crowds attending the Democratic Convention in Baltimore this week, a 2 days' race meet began on the mile dirt track at Laurel yesterday. The convention was too attractive, however, and less than three hundred people attended the first day. Burman won back the Remy brassard in his Blitzen Benz, covering 3 miles in 3:20. He had little competition, as only Elmer MacDonald, in the Benz 110, and I. C. Barber, a local driver, in a Warren-Detroit, opposed him. They finished in the order namer. Burman won the 21-mile race in 27:32, with Raimey's Ohio 99 second and French's Lozier third. The summaries:

Non-stock, 161 to 230 cubic inches, 5 miles

No.	Car	Driver	Time
1.	Warren-Detroit	I. C. Barber	6:15
2.	Reo	Frank Stewart	

Non-stock, 231 to 300 cubic inches, 5 miles

1.	Ohio	John Raimey	5:37
2.	Kline	C. C. Fairman	
3.	Mercer	Frank Blair	

First heat for Remy Brassard, 3 miles

1.	Blitzen Benz	R. Burman	3:20
2.	Benz 110	E. MacDonald	
3.	Warren-Detroit	I. C. Barber	

Non-stock, 600 cubic inches and less, 5 miles

1.	Cutting	R. Burman	5:22
2.	Kline	J. W. Minker	
3.	Lozier	H. W. French	

Exhibition Mile

Blitzen-Benz	R. Burman	:58 3-4

Non-stock, 600 cubic inches and less, 25 miles

1.	Cutting	R. Burman	27:32
2.	Ohio	J. Raimey	
3.	Lozier	H. W. French	

Free-for-all, 5 miles

1.	Benz	E. MacDonald	4:12 1-2
2.	Kline	C. C. Fairman	
3.	Lozier	H. W. French	

The second day's racing brought out the same fields as the day before. The crowd was very small and the promoters will lose a great deal of money on the venture. The results:

5-mile race

Car	Driver	Time
Mercer	Frank Blair	6:04
Warren	I. C. Barber	
Reo	F. Stewart	

Second heat for Remy Brassard, 3 miles

Benz	E. MacDonald	5:11 1-4
Benz	R. Burman	

Third heat for Remy Brassard, 3 miles

Benz	R. Burman	3:06 1-2
Benz	E. MacDonald	

5-mile race

Cutting	R. Burman	5:34
Ohio	J. Raimey	
Warren	I. C. Barber	

5-mile race

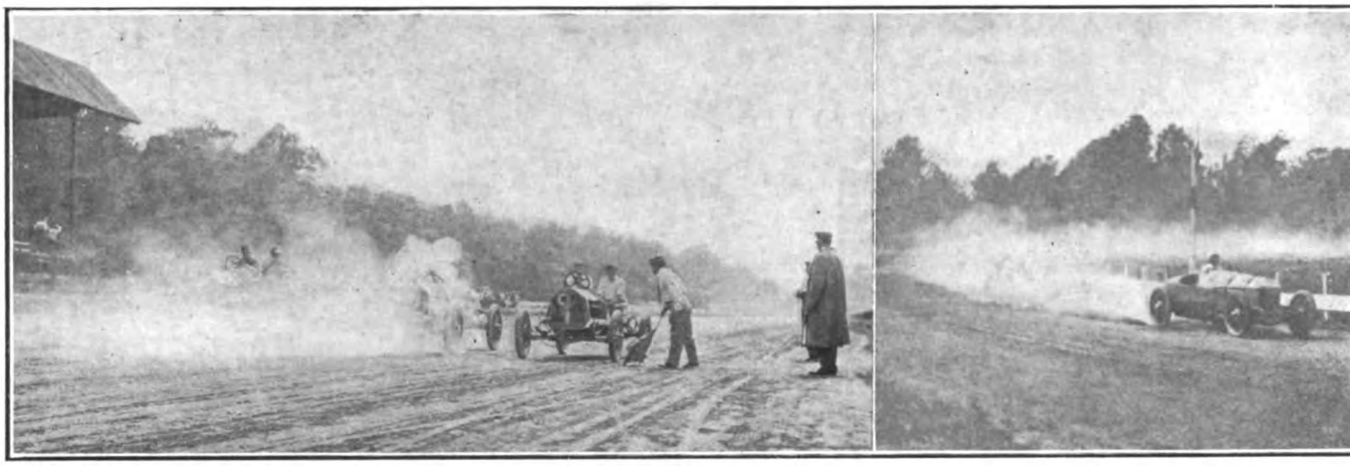
Ohio	J. Raimey	5:55
Warren	I. C. Barber	
Mercer	Frank Blair	

Free-for-all handicap, 5 miles

Benz	E. McDonald (Scratch)	6:05 1-2
Warren	I. C. Barber	
National	C. Campbell	

Australian pursuit race

Benz	R. Burman (8 1-2 miles)	8:19 1-4
National	C. Campbell	



Start of Event 1, won by Buick. Menker in Klinekar passing Blocksom in Stutz in 10-mile race

Klinekar Stars at Belmont

Wins Free-for-All and 10-Mile Events —Morton's Mercer Overturned; Nobody Hurt

Three Unsuccessful Attempts to Lower Burman's Mile Track Record of 54.26

PHILADELPHIA, June 29—All things considered, the initial race meet of the Belmont Motor Club held this afternoon at the Belmont Driving Park, Narberth, was an ambitious attempt, and the disappointingly small crowd that attended was amply repaid for any discomfort due to the sweltering heat of the hottest day so far this summer by the exciting finishes in several of the events. To further add to the excitement an accident occurred which at first was thought to have had a serious termination. The accident occurred during the running of the sixth event, a 50-mile free-for-all race with an entry list of ten, only four of which, however, faced the starter. These were a Stutz, driven by S. R. Blocksom; a Mercer, driven by W. D. Morton; a Fiat, piloted by William Frietag, and a Klinekar, John Menker, driver. Early in the contest the Fiat was forced to drop out, and the three survivors put up the prettiest contest of the day. On the seventeenth lap the Mercer entry crashed into the fence on the far side of the track, throwing both driver and mechanician out. The spectators crowded on the track and threatened further danger, as the Stutz and the Klinekar were still tearing around the oval. The race was immediately stopped. The Mercer car was put out of commission but neither W. D. Morton nor his mechanician was seriously injured. The contest was resumed between the Stutz and Klinekar on the eighteenth lap, at which point the former car held a commanding lead. A succession of tire troubles toward the conclusion of the race, however, caused the Stutz to lose much valuable time, which the Klinekar was not slow to take advantage of, and when two flat tires, one in the forty-seventh and the other in the forty-ninth lap occurred, the Klinekar breezed in a winner by a comfortable margin. The latter car was not without its tire troubles either, but they occurred less frequently.

In the 1-mile exhibition for the track record, although three attempts were made, Burman's 54.26 seconds still stands, the nearest approach to it being made by John Menken in a Klinekar, who negotiated the mile in 58 seconds flat, which, by the way, was the fastest lap of the afternoon.

The program was marred somewhat by the withdrawal of several of the entries, so that with one exception the fields were small. By the application of liberal quantities of calcium chloride, assisted by an autocar sprinkling wagon that made trips around the track during intermissions between events, the raising of dust was reduced to a minimum.

Event No. 7, a 10-mile handicap race, furnished plenty of thrills, William Frietag in his Fiat, starting from scratch, wearing down his six opponents one by one, winning in 10 minutes 50 seconds, the Empire car, driven by R. D. Smith, Jr., finishing second.

Event No. 3, 10 miles, was featured by the establishment of a record for cars of 301 to 450 cubic inches piston displacement. the Klinekar driven by John Menker covering the ten laps in 9 minutes 55 seconds, although the record will not be official owing to there being no timing device to record it, as required by the A. A. A. The summaries:

Non-stock; 5 miles; 161 to 230 cubic inches

No.	Car	Driver	Time
9	Buick	Eddie Bauer	6:02 2/5
18	Cartercar	H. Baker	6:03 4/5
12	Empire	R. D. Smith	....

Non-stock; 5 miles; 231 to 300 cubic inches

No.	Car	Driver	Time
14	Bergdoll	E. Homan	6:00 4/5
3	Mercer	W. D. Morton	....
4	Mercer	Harvey Ringler	....
1	Klinekar	C. C. Farman	....
7	Schacht	Jas. M. Gray	....

Non-stock; 10 miles; 301 to 450 cubic inches

No.	Car	Driver	Time
2	Klinekar	John Menker	9:55
28	Stutz	S. R. Blocksom	5;56 4/5
17	G. J. G.	Al Millichap	....

1-mile exhibition to lower track record of 54.26 seconds

Car	Driver	Time
Fiat	William Frietag	1:01
Klinekar	John Menker	:58
Chadwick	Willie Haupt	1:02

Free-for-all; 50 miles

No.	Car	Driver	Time
1	Klinekar	John Menker	53:39
28	Stutz	S. R. Blocksom	....

10-mile handicap

No.	Car	Driver	Time
12	Empire	Wm. Frietag	10:50
15	Fiat	R. D. Smith, Jr.	....
7	Schacht	Jas. M. Gray	....

Handicap for non-winners of previous events; 5 miles

No.	Car	Driver	Time
12	Empire	R. D. Smith, Jr.	5:39
7	Schacht	Jas. M. Gray	....
4	Mercer	Harvey Ringler	....

Hoosiers to Honor Speedway Builders

INDIANAPOLIS, IND., July 1—The business interests of the city will pay a pleasing tribute to Carl G. Fisher, A. C. Newby, F. H. Wheeler and James A. Allison, owners of the Indianapolis Motor Speedway, when they give a dinner at the German House to-morrow evening. The dinner is to be in recognition of the services of the owners of the speedway to their home city and will be one of the first honors of the kind ever paid to an Indianapolis citizen.

There will be about 100 guests, representing the substantial business interests of the community.

Mr. Fisher and Mr. Allison have recently begun the construction of Speedway, the first horseless city in the world. They are also owners of the Prest-O-Lite Company, and Mr. Fisher is the Indiana agent for the Packard and Stutz. Arthur C. Newby is secretary and treasurer of the National Motor Vehicle Company, while Mr. Wheeler is a member of Wheeler & Schebler, carbureter manufacturers, and of the Langenshamp-Wheeler Brass Works.

Unclaimed Prizes Distributed

INDIANAPOLIS, IND., July 1—The Indianapolis Motor Speedway Company has divided $2,100, representing the eleventh and twelfth prizes in the 500-mile race Memorial Day, among the drivers who were unable to finish on account of accidents. As only ten cars finished, the two last prizes were not claimed. The $2,100 has been distributed on a basis of the number of laps covered by each driver. It was found that the fourteen cars failing to finish covered 1,093 laps, which gave a basis of $1.9213 a lap for each of the fourteen drivers.

Distribution of the $2,100 has been as follows: Stutz, Anderson, 80 laps, $153.70; Mercedes, De Palma, 199 laps, $382.34; Case, Disbrow, 67 laps, $128.73; Case, Herrick 54 laps, $103.75; Mercedes, Wishart, 92 laps, $176.76; Lexington, Knight, 7 laps, $13.46; Simplex, Dingley, 116 laps, $222.87; Cutting, Burman, 157 laps, $301.54; Firestone-Columbus, Rickenbacher, 43 laps, $82.62; Marquette-Buick, Liesaw, 72 laps, $138.34; McFarlan, Marquette, 63 laps, $121.04; Opel, Ormsby, 7 laps, $13.46; Lozier, Matson, 110 laps, $211.34, and National, Bruce-Brown, 26 laps. $49.95.

Davenport's Gala Motor Fourth

DAVENPORT, IA., July 1—Davenport automobilists are to have a special gala day July 4, the annual hill climb of the Davenport Automobile Club and the speed demonstrations of Bob Burman at the mile track in the afternoon to be the features. The hill climb will be held on Rock Island street, from Third to Tenth street. Two blocks are to be allowed for a flying start, the machines to be timed on five blocks. The record for the distance is 17 4-5 seconds, made by Pete Petersen of the P. C. Petersen Auto Company in a Pope-Hartford last year.

Ford Enjoins Price Cutters

DAYTON, O., July 2—The United States District Court at Cincinnati has decided in favor of the Ford Motor Company in its suit against the Union Motor Sales Company, of this city, in which unfair competition and violation of certain patent rights belonging to the complainant company were involved. The ruling of the court orders a temporary injunction. In the suit it was charged that the Union Sales Company advertised Ford automobiles at less than list price and the manufacturing company proceeded against the Dayton concern.

Run to Wildwood Races

Many Quaker City Motorists Will Tour To Seaside Resort to See Straightaway Contests

Thirteen Prizes Will Be Hung Up for the Roadability Event—Good Fields for the Races

PHILADELPHIA, June 29—The roadability run under the auspices of the combined Boards of Trade of Wildwood, North Wildwood and Wildwood Crest from Philadelphia to Wildwood, N. J., next Wednesday morning, culminating in a race meet in the latter resort on Independence Day, promises to be one of the largest and most successful of its kind yet attempted. Taking part in the run down as non-contestants will be a score or more of racing cars that will take part in the contests to be waged on Thursday.

The itinerary as mapped out by the pathfinding Stoddard-Dayton Saybrooke car includes Gloucester, Westville, Woodbury, Swedesboro. At the latter town the tourists will be joined by a contingent of local machines, to whom two cups, the Ford Hotel Cup and the Clark Hotel Cup, will be awarded the cars running nearest the legal speed limit from Swedesboro to Wildwood, N. J. From Swedesboro the tourists will touch Alloway, Salem, Bridgeton, Millville, Port Elizabeth, Dorchester, Leesburg, Cape May Court House, thence into Wildwood.

In addition to the two special cups for Swedesboro contestants only, eleven others will be awarded, including two for the women's division, four main prizes and five supplementary ones. To the car finishing nearest the secret time for the full distance, which will be set by J. Thompson Baker, mayor of Wildwood, the prize is $50 in gold; second nearest, the Hotel Ridgway Cup, Camden, N. J.; third, Colonial Hotel Cup, Wildwood, N. J.; fourth, Hutchison Motor Company Cup, Woodbury, N. J.

For the secret intermediate control feature of the run, to the car nearest the legal speed limit at the first control (Alloway, N. J.) will be presented the Alloway Hotel Cup; second control (Salem, N. J.), the Nelson House Cup; third control (Bridgeton, N. J.), the Bridgeton Cup; fourth control (Wildwood, N. J.), the Ruric Hotel Cup.

A majority prize of $50 in gold is also hung up for the greatest number of cars of any one make entered in the run by a Philadelphia agent and, finally, two special prizes, one a sterling silver chatelaine bag and the other a sterling silver chatelaine wrist watch, will go to women contestants. The automobile races on July 4th will all be one-mile straightaway.

Athletes Beat Motorists

Chicago Athletic Association Team Wins from Automobile Club in Annual Roadability Event

Heavy Penalties for Two of the Latter Team Upset Good Work of Their Mates

CHICAGO, June 29—The fifth annual interclub reliability team match between the Chicago Athletic Association and the Chicago Automobile Club, which was run Thursday and Friday of this week to Milwaukee and return, was won by the former club by the closest margin that ever has marked a match between the two organizations, the Cherry Circle having 46.7 points against it and the Chicago Automobile Club 58.

This is the great amateur event of the year, no one identified with the trade being permitted to participate as contestants. Because of the political conventions the entry list was not as large as was expected, there being at least a dozen scratches because of this. Still, the C. A. A. had twelve cars in line and the C. A. C. eleven.

The contest was run under grade 3 of the A. A. A. rules, penalizations being only for work done on the road and for being late at controls. This produced an interesting contest and the result is a demonstration of the skill of the amateur drivers, for of the twenty-three contesting fifteen made perfect scores. It was hard luck for the Chicago Automobile Club to lose, for only two of its drivers were penalized, while the second day the entire team went clean. At the end of the first day's run the Cherry Circle looked an easy winner with only 2 points against it, but yesterday, coming back from Milwaukee, S. F. Weatherly, in a Pathfinder ran into a ditch near Libertyville, sinking to the hubs. He had a couple of motor stops charged against him and also had to clean out his carbureter feed line with an air bottle,

A fine stretch of road near Lake Geneva

the line having become clogged because of the mud. All this work gave him 43 points which brought the C. A. A. near defeat.

The other five cars penalized on the C. A. A. side got their black marks for trifling causes. Frank Wentworth in a Rambler drew 4 points because his lighting system shortcircuited his ignition. The other four were charged with motor stops.

The first day's run was to Milwaukee, the mileage being 137, while the route back yesterday was but 120 miles. While at the night stop the Chicagoans were entertained by the Milwaukee Automobile Club at its country home.

TABLE SHOWING PENALIZATIONS IN THE INTERCLUB-RELIABILITY MATCH RUN BETWEEN THE CHICAGO ATHLETIC AND AUTOMOBILE CLUBS

Advertised Cars as Stock

Agencies Suspended for Misleading Statements Regarding Victories at Indianapolis and Elsewhere

Referee and Promoter Disciplined for Disregarding Contest Board Ruling—Records Granted

FOR breaking the rule about advertising the performances of contestants in non-stock events as being those of stock cars, three automobile agencies fell under the ban of the American Automobile Association at its meeting last week. The disciplined agencies are as follows: The Wisconsin Auto Sales Company of Milwaukee and the Howard Automobile Company of San Francisco were suspended until January 1, 1913, for advertising the performance of the winning National in the recent 500-mile race at Indianapolis as a stock car victory. The Empire Motor Car Agency of Boston was given a similar sentence for claiming that a Stutz car that competed in a race at Salem, N. H., was a stock car running under non-stock conditions.

On a dusty piece of road near Mucknowago

E. G. Kuster, official representative of the A. A. A.; R. P. Hillman, referee of recent California contests, and A. M. Young, promoter of the Santa Monica road races and other events, were disciplined. Mr. Kuster's resignation was accepted and Mr. Hillman was declared ineligible as an official until January 1, 1913, and Mr. Young was barred for a similar period.

The matter in question was the disregarding of a telegraphed ruling of the Contest Board defining the status of the E-M-F—Flanders entries.

In order to cover the point more definitely than it is in the present rules the following amendment, effective August 1, has been adopted;

"No car with a bore, stroke and piston displacement of a different size from the regularly catalogued product of a manufacturer shall be entered in any sanctioned event until its manufacturer shall have filed with the Contest Board, on official blanks provided for the purpose by the Contest Board, sworn certificates giving the bore, stroke, number of cylinders, total piston displacement, horsepower and year and model name of the cars, and such cars must be officially entered, programmed and advertised in strict accordance with such registration.

"All other cars must be entered, programmed and advertised in strict accordance with catalogued specifications.

"Rule 113 (on Road Racing). REPAIR PITS. There shall be located at the start and finish line one repair pit for each car started, not less than 15 feet long and 8 feet wide. The pits must be located on the right of the course in the direction in which cars are traveling. If located on the same side and in front of the grandstand, there must be an intervening distance of not less than 15 feet between the pits and the stand."

The following official records made at the recent Indianapolis race were allowed:

Distance, Miles	Car	Driver	Time
100	Fiat	Tetzlaff	1:13:37.25
150	Fiat	Tetzlaff	1:49:52.84
200	Fiat	Tetzlaff	2:25:59.52
250	Fiat	Tetzlaff	3:07:13.94
300	National	Dawson	3:48:49.30
350	National	Dawson	4:25:15.27
400	National	Dawson	5:04:14.23
450	National	Dawson	5:44:04.54
500	National	Dawson	6:21:06.03

(NOTE.—The time of the No. 4 Mercedes, driven by DePalma, bettered all of the above times, with the exception of the 500-mile mark, but under Rule 79 of the 1912 Contest Rules no record at an intermediate distance is allowable unless the car finishes the event. The No. 4 Mercedes discontinued the race in the 199th lap.)

Alco Truck Is Nearing Omaha

MARSHALLTOWN, IA., July 2—The transcontinental trip of the Alco 3-ton has proved successful so far and the car is now approaching the mid-way point, having averaged 12 miles an hour during its running time to date. The car is delivering 3 tons of freight to a Pacific coast consignee. The first half of the trip was routed over good roads and the car still has to face the rough going of the Rocky Mountains and the desert country.

Locomobile 5-Ton Truck

Motor Develops 45 Horsepower and All Parts of the Machine Are Especially Designed for Commercial Work

Increased Factors of Safety, Increased Bearing Areas and Decreased Pressures and Strains Important Features

AFTER investigating conditions in the commercial vehicle field for a number of years, studying the design, materials and construction most suitable for such work and testing out an experimental machine, the Locomobile Company, Bridgeport, Conn., has brought out a 5-ton truck. The main features of the experimental machine have been retained but improvements have been made wherever the tests demonstrated their feasibility.

The design of the truck shows a very compact arrangement, affording a very large platform space, and at the same time making the vehicle one which is easily managed, only a 27 1-2-foot radius being needed to make a complete turn.

The driver's seat is located over the motor, thus affording the maximum platform space and carrying capacity for the wheelbase, and enabling the operator to handle the truck more easily.

Parts Built for Hard Service

In the production of this truck no parts have been used which were designed for any of the types of pleasure cars that the company has constructed. Every part has been designed for the truck, so that it will be able to withstand the more severe duty to which trucks are subjected.

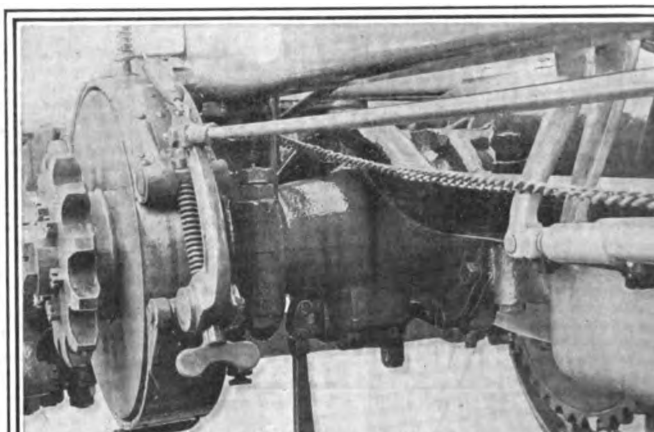
The general dimensions of the truck are as follows: Wheelbase, 140 inches; tread, front, 65 inches; rear, 70 inches. Height above ground, loaded: frame, 39 1-2 inches; platform, 46 inches; driver's seat, 72 inches. Platform length, 14 feet; width, 6 feet (or wider). Width over hub caps, 85 3-4 inches. Length over all, 226 1-4 inches.

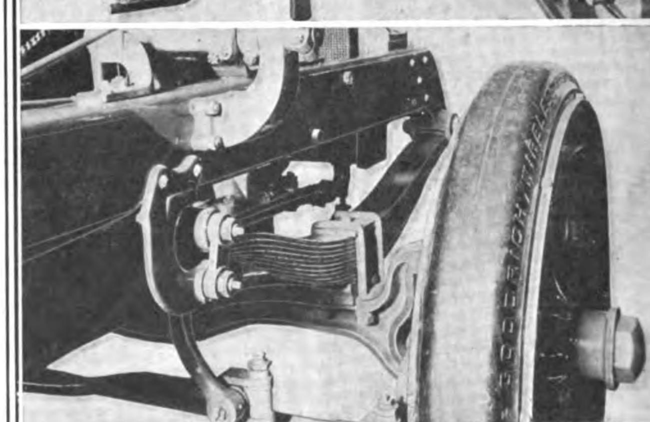
A self-contained, continuous-flow lubricating system, which has proven very economical, has the added advantage that its regulation cannot be altered by the operator, and a specially designed ring governor, which prevents the motor speed from exceeding 900 r.p.m., has been added.

The water outlet pipes, instead of being made separately, are cast integral with the cylinder waterjacket caps, to eliminate the danger of leaky joints.

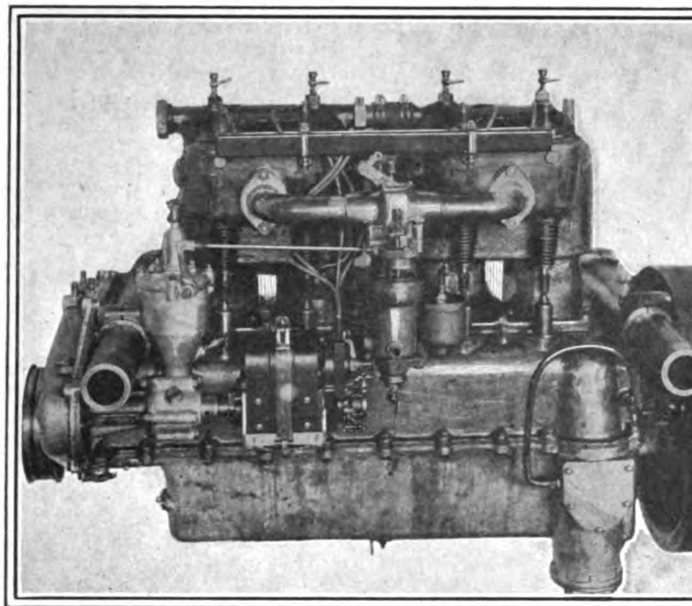
The double chain drive gives great strength, flexibility and the maximum tractive effort. The motor is of the four-cylinder, water-cooled type, having a bore of 5 inches and a stroke of 6 inches, and developing 45 horsepower at 900 R.P.M., and was made especially for truck service.

The diameters of the valves have been increased, as well as those of the admission and exhaust pipes, thus reducing gas velocities; and the valve stem guides, instead of being cast integral with the cylinders, as is the usual practice, are cast separately and forced into place so they can be easily replaced.

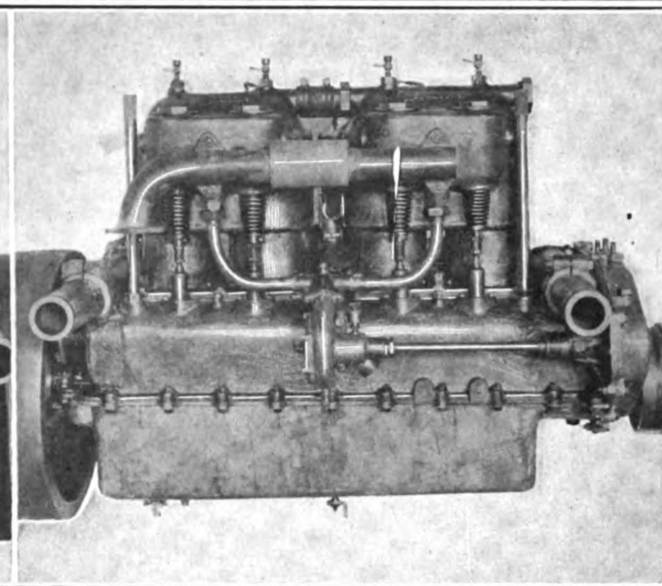




Arrangement of brake and drive sprocket on the jackshaft
Front suspension, one shackle bolted on, the other welded



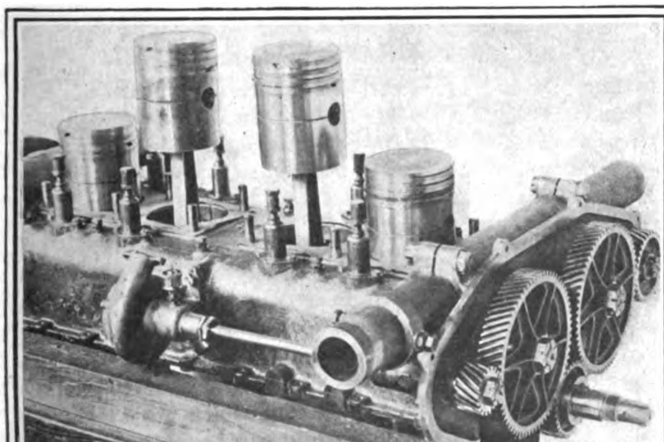
Intake side of Locomobile 5-ton truck motor, showing governor.



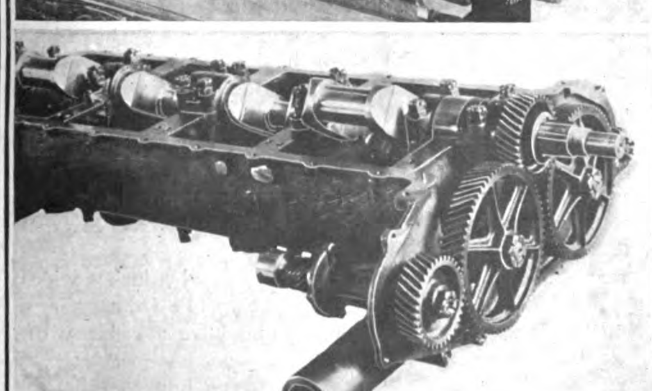
Exhaust side of motor, showing independent water pump shaft

The exhaust manifold is made in two parts, one of which telescopes inside the other, thus obviating any stresses between the two pair of cylinders due to the longitudinal expansion of a solid manifold when heated, which would tend to throw the wristpin and crankpin bearings out of proper alignment.

Radical changes have been made in the method of supporting the crankshaft, and in the size of the crank and connecting-rod bearings, so that the pressures per square inch of projected bearing area could be cut down to the minimum. Instead of a three-bearing crankshaft with bearings 1¾ inches in diameter, such as was used in the pleasure and public service cars, a five-bearing crankshaft, with bearings 2¼ inches in diameter, is used on the truck. In consequence, the crankshaft bearings in the truck have a projected area of 41.34 square inches, as against the projected bearing area of 21.54 square inches on the pleasure and public service cars. This tends to increase the life of the bearings and to minimize motor troubles. The crankpin and wristpin bearings also show a marked advance in size over previous practice.



Cylinders removed, showing engine pistons and connecting rods



Top of crankcase removed, showing crankshaft and timing gears

The connecting-rods are of I-beam section, drop forged from a steel strong enough to give the rods a factor of safety of 25.

The crankpin bearing caps are held in place by four studs to which they are fastened by means of a lock washer, plain nut, castellated lock nut and cotter pin.

The cast-iron cylinders are cast in pairs and have very large waterjackets. Each cylinder pair is fastened to the crankcase by means of six ⅝-inch studs, nuts and castellated lock nuts.

The cylinders, after being bored and reamed, are ground to a finish, as are also the pistons. The pistons are each fitted with four ¼-inch rings above the wristpin, each of which has been annealed to relieve it of all internal strain, and has been carefully ground and finished to an exact fit.

In the crankcase the makers have followed their standard practice by using bronze, thus insuring alignment of the crank bearings and eliminating any danger of crystallization under the road shocks to which a truck is subjected.

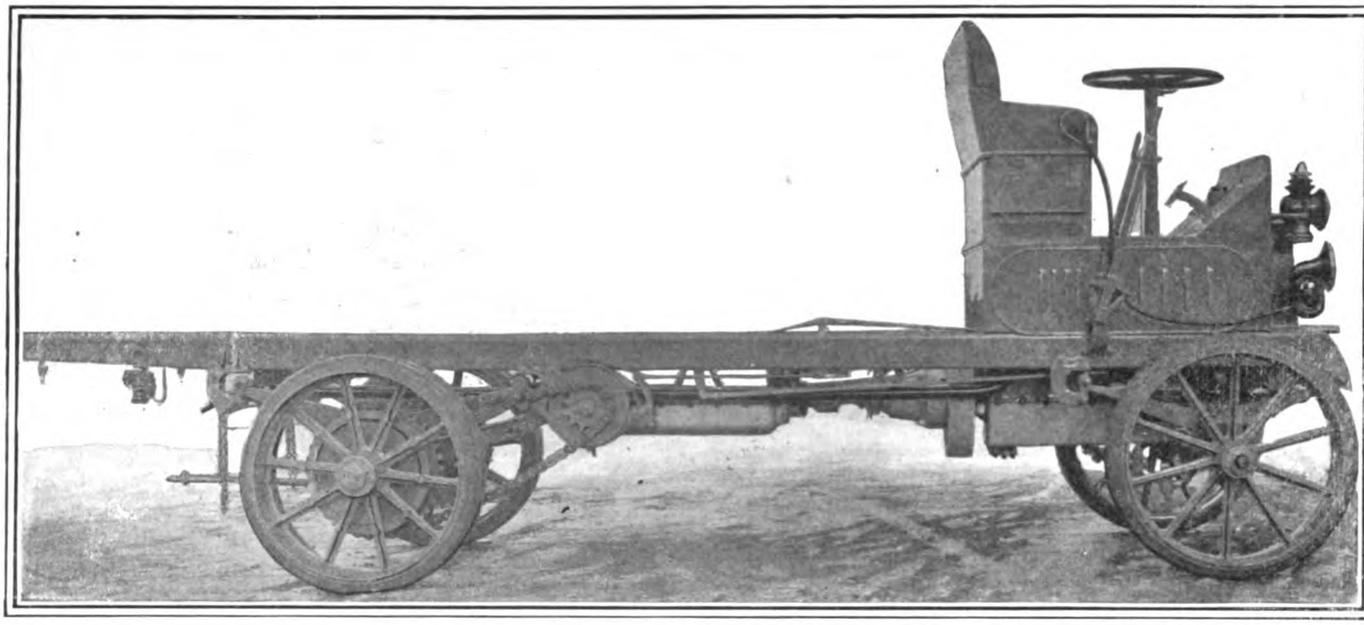
The crankcase is supported front and back from the channel side member of the frame in a manner which makes the motor easy to remove and insures alignment upon replacement.

Steel Tubes Support Motor

Two 3-inch steel tubes pass through holes bored in suitable lugs in the front and rear of the crankcase and are held firmly in position by means of clamp bolts, which draw together the slotted ends of the two bearings. Cast steel bearing brackets, bolted rigidly to the frame after the motor has been properly aligned, support the tubes and keep them in place by means of caps bolted down.

The governor, which is located on the left-hand side of the motor in front of the magneto, is of the vertical ring type, and is driven from the magneto driving shaft by spiral gears. The ring is hung from the shaft at a normal inclination to the horizontal plane of 53 degrees and carried by two cams. It is held in this position by a spring, but as the motor speed increases the tension of this spring is overcome, and the ring seeks to assume a horizontal position. The governor is connected by linkage to a butterfly valve in the carbureter, which remains wide open at all speeds below 900 r.p.m., at which speed the governor cuts off.

The carbureter is of standard Locomobile design. It is of the float-feed type and is fitted with both a hot air regulator and



Locomobile 5-ton truck with platform body; 70 per cent. of the load capacity is carried on the rear wheels

a hot water jacket. Only a single jet is used, which insures easy starting; but this single jet, owing to its design, performs the functions of both the single and multiple type jets. This is accomplished by elongating the jet so that the customary hole in the top is some distance above the level of the gasoline in the float chamber. Supplementary holes are drilled in the jet just above the gasoline level. Gasoline for low motor speeds is supplied through the supplementary openings, the necessary excess for high speed being furnished by the hole on top, the gasoline being drawn through it by the increased suction due to the higher velocity of the mixture through the vaporizing chamber. An air adjustment is arranged on the dash.

The water-cooling system contains 8 gallons of water. Instead of having a rigid return water connection on top of the cylinders, the cylinder water jacket caps have return pipes cast into them. The connection with each other and with the radiator is made with rubber hose connections, eliminating any danger of breakage due to vibration, and relieving the water jacket caps of all strain.

The radiator is protected by being set behind a large channel cross-member, and is hung in a novel manner.

A large aluminum fan, cast in one piece and driven by a 1¾-inch flat belt, is provided, the driving pulley being on the crankshaft. This fan is mounted on two ball bearings contained in an eccentric case, which, by loosening a nut, can be turned, thus adjusting the tension of the belt and facilitating any necessary belt replacements.

Clutch Alignment Is Assured

The dry disk clutch installed in this truck is self-contained and is carried on the flywheel alone, preventing any possibility of the plates getting out of alignment. Its connection with the transmission is through a drive shaft which has a universal action. The seven driving disks, which engage with six hardened and ground driving bolts attached to the clutch drum bolted to the flywheel, are made of ⅛-inch sheet steel. The seven driven disks, which are mounted on the clutch disk retainer, are made of ⅛-inch sheet steel and are lined on both sides with a non-burn material 5-32 inch thick. The driven members are provided with a clutch brake.

The transmission is of the electric type, with four speeds forward and a reverse. The transmission case proper, which is a manganese bronze casting having a tensile strength of 68,000 pounds per square inch, comprises the top, instead of the bottom, half of the transmission case, contrary to usual practice. The bronze top half is supported from the frame, and the clutch pinion, countershaft and mainshaft are attached to it by collars. The aluminum oil pan bolts on from the bottom, and, in consequence, can be dropped to inspect the gears. The clutch pinion, countershaft or main shaft can be individually removed without dropping the transmission or disturbing any other part.

The transmission case is hinged in front to a channel section cross member and is supported behind by the jack shaft housings, which are bolted to it so as to form an integral part. These housings are held by spherical bearings in cast steel brackets bolted to the chassis side channel members. This arrangement prevents any temporary deflections or distortions in the chassis from straining any part of the transmission or from throwing it out of alignment, as the transmission case will adjust itself in the spherical bearings..

Features of the Transmission

The gears, which have a 1½-inch face, are made of an especially tough alloy steel heat-treated and very accurately machined. The teeth are generated on a gear shaper instead of being milled in the usual manner, so that friction losses are reduced as much as possible.

The main shaft, instead of being square, has feather keys cut from the solid material, this design giving a greater cross-section and consequently greater strength.

The contracting type foot brakes are each 13½ inches in diameter and 3 inches wide, giving the foot brakes an effective braking area of 225 square inches. Owing to the chain reduction, these brakes have as much braking effect on the rear wheels as the internal expanding emergency brakes, which are 18 inches in diameter, with a 4½-inch face, and a total effective braking area of 355 square inches.

The truck is equipped with a 2-inch pitch chain with rollers 1⅛ inches in diameter and 1¼ inches wide, whose strength is 44,000 pounds.

The rear axle is made of alloy steel and is rectangular in shape, being 3½ inches high by 2½ inches wide.

The wheels are carried on roller bearings guaranteed to carry 17,500 pounds per axle, a figure which would not be reached even under the maximum overload conditions.

The rear springs, which are 50 inches long and 3 inches wide, have a normal capacity of 6,000 pounds each. The front springs are 42 inches long and 3 inches wide, and have a capacity of 2,000 pounds.

The truck is fitted with a 3-inch jack spring hung parallel to and above the rear axle from a spring chair supported by diagonal frame members heavily reinforced by gusset plates, top and bottom. This jack spring was installed to absorb severe road shocks and also to take care of any overloading of the rear springs.

One important feature in the spring arrangement is the device used in connection with the spring link bolts and shackles. In order to prevent wear, the hardened steel link pins which pass through the bronze spring bushings are welded to one shackle by an oxy-hydrogen process, making them a solid unit and preventing any relative movement between them. The other shackle is bolted on.

Heavy sprags, which can be dropped from the driver's seat by a chain on the steering post, are mounted on the rear axle.

Cast Steel Wheels Employed

The frame is strong and well designed. It is made throughout of pressed alloy channel steel, the side members of the frame being 6 inches high by 2½ inches wide by 5-16 inch thick, and held together by six channel section cross-members, heavily reinforced by large steel gusset plates.

The truck is equipped with 40-inch cast steel wheels, which are stronger than wooden wheels, and are not affected by road jars and vibration. The cast steel rear wheels weigh over 50 pounds less than similar wooden wheels. The front wheels are fitted with a single 6-inch solid tire, while the rear wheels each carry two 6-inch interchangeable solid tires.

The steering gear is of the screw and nut type, a triple thread screw of large pitch being used to lessen the wear. The horizontal steering wheel gives the operator greater leverage in steering, and subjects him to less fatigue.

The superstructure carrying the driver's seat is so arranged that it can be easily removed, in case it is wanted to grind the valves in the motor, without disturbing the control.

The gasoline tank, holding 25 gallons, is located under the driver's seat, and is connected with the carbureter by means of a flexible metallic tubing.

About 70 per cent. of the capacity load is carried on the rear wheels. This distribution gives maximum traction without loading the wheels beyond their effective adhesive weight, lightens the load on the front wheels, and offers the minimum load resistance, making steering easy and equalizing the tire wear between the front and rear wheels.

Standardization in the Drafting Room

H. Allen Suggests that Conservation of Time, Energy and Money Is Possible Through the Use of Standard Tables of Sizes in Properly Laying Out the Work Before It Reaches the Shop

STANDARDIZING the drafting room is one of the biggest factors in this department of the factory today. This standardization work can be carried on in many different ways. Each act of standardization calls for a tabulation which should be given to each draftsman. One example of this occurs in drilling holes for cotter-pins. Draftsman No. 1 might use a certain size drill and draftsman No. 2, working in the same drafting room, would indicate a different size drill for this work. As a solution of this difficulty, my suggestion is adopting the standards for cotter-pin drill sizes of Table No. 1. Give each draftsman a copy of this table and insist that all holes for certain size cotter-pins be of the same size, irrespective of the person doing the work.

TABLE NO. 1—STANDARD SIZE DRILLS FOR SPRING COTTER-PINS

Size of Pin	Size of Drill
1/16-inch	No. 48, .076 inch
3/32 "	" 38, .101 "
1/8 "	" 28, .140 "
5/32 "	" 21, .159 "
3/16 "	" 12, .189 "
7/32 "	" 2, .221 "
1/4 "	" F, .257 "
5/16 "	" O, .316 "

As 1/16, 3/32 and 1/8-inch pins are used more than any other, it is very easy to remember for 1/16 pin to use No. 48 drill; for 3/32 use No. 38 drill, and for 1/8-inch pin use No. 28 drill.

The adoption of standard sizes for drills and standard sizes for bosses is an excellent idea. Such a tabulation is shown in Table No. 2, of which each draftsman is given a copy. This table is divided into three divisions:

First, pipe tap bosses; second, S. A. E. bolt bosses; and third, U. S. S. cap screw and coupling bolt bosses.

The first column in each division gives the size drill to use for each given tap; the second column gives the size of tap and the third column gives the size of boss. The benefit of the last column can be readily seen, as it stops a draftsman from having to figure out each time what size to make each boss for a given size tap. For instance, one man might make a boss for a 1-8-inch pipe top 5-8-inch in diameter; another man would make it 7-8, and so on; another would lay it out and when he thought it was big enough he would then dimension it. This makes the bosses of all different sizes by different draftsmen. With this table, a draftsman has it right before him and knows right away what size to make the boss. For example: He is using a 1-4-inch pipe tap. Glancing at the table, he finds the size of boss to be 1 inch and also the tap drill size 29-64, which he puts on the drawing. Thus he uses drill 29-64 and tap 1-8-inch pipe. It will thus be seen that all information is given, even to the drilling department. The last division is divided off into different shapes of the screw heads. For instance: The third column in the third division calls for the size of boss for a flat, hexagon and square head bolt.

TABLE NO. 2.—STANDARD SIZE DRILLS AND STANDARD SIZES OF BOSSES

Pipe Tap Bosses			S.A.E. Bolt Bosses			U.S.S. Cap Screws and Coupling Bolt Bosses				
Size Drill	Size Tap	Size Boss	Size Drill	Size Tap	Size Boss	Size Drill	Size Tap	Size Boss Flat, Hex., Square	Size Boss Ad. Fill. Button	Size Boss Coupling Bolt
In.	In.	In.	In	In.	In.	In.	In.	In.	In.	In.
27/64	1/8-27	11/16	No. 4 (.209)	1/4-28	3/4	No. 9 (.196)	1/4-20	13/16	7/8	13/16
29/64	1/4-18	1	17/64	5/16-24	13/16	1/4	5/16-18	1	1 1/16	1
19/32	3/8-18	1 1/4	21/64	3/8-24	1 1/16	5/16	3/8-16	1 1/8	1 3/16	1 1/8
23/32	1/2-14	1 7/16	25/64	7/16-20	1 3/16	23/64	7/16-14	1 3/16	1 5/16	1 3/16
15/16	3/4-14	1 3/4	29/64	1/2-20	1 1/4	27/64	1/2-13	1 5/16	1 3/8	1 5/16
1 3/16	1 -11½	2 1/8	1/2	9/16-18	1 3/8	31/64	9/16-12	1 1/2	1 1/2	1 1/2
1 [illegible]	1¼-11½	2 9/16	9/16	5/8-18	1 1/2	17/32	5/8-11	1 5/8	1 3/4	1 5/8
1 [illegible]	1½-11½	2 7/8	5/8	11/16-16	1 [illegible]	41/64	3/4-10	1 7/8	2 1/16	1 7/8
2 3/16	2 -11½	3 3/8	11/16	3/4-16	1 [illegible]	3/4	7/8-9	2 3/16	......	2 3/16
2 11/16	2½-8	4	51/64	7/8-14	1 7/8	53/64	1 -8	2 3/8	......	2 3/8
3 5/16	3 - 8	4 3/4	59/64	1 -14	2 1/8	63/64	1 1/8- 7	2 7/16	......	2 7/16

The third way in which drafting room practice can be standardized is in the use of certain drill sizes with any taper-pin. It was customary to take the small end of the taper-pin and use a corresponding size of drill, but with the method outlined in Table No. 3 it does not leave so much to ream. For example: For a No. 4 pin 3-4-inch long, use a No. 1 drill, .228 inch; for a No. 4 pin 2 inches long, use a No. 4 drill, .209 inch; and the same way all through the table. It is best to mark pieces for a taper-pin thus: "Drill No. 4 (.209 inch) and rear at assembly for No. 4 taper-pin." Thus the drilling can be done ahead of time and by jigs, and the reaming can be done at assembly.

TABLE NO. 3—SHOWING POSSIBLE STANDARDIZATION IN DRILLS FOR TAPER-PINS

No. of Pin	Diam. at Large End A	Diam. at Small End B	Length of Pin C	Size of Drill to Use	Corresponding No. of T.P. Reamer	Diam. at Small End T.P. Reamer
0	.156	.140	3/4	29 (.136)	0	.135
0	.156	.135	1	29 (.136)	0	.135

Another table that is very useful in laying out work for clearance in close quarters is for the size of machine screw nuts. I do not recall ever seeing it in any of the handbooks. Table No. 4 shows this.

TABLE NO. 4—FLATS OF HEXAGONAL NUTS SAME AS FLATS OF SQUARE NUTS

Nut Size	Across Flats	Thickness
4–36	9/32-inch	3/32 inch
6–32	5/16 "	1/8 "
8–32	11/32 "	1/8 "
10–24	3/8 "	9/64 "
12–24	7/16 "	5/32 "
14–20	1/2 "	3/16 "
16–18	17/32 "	13/64 "
18–18	9/16 "	1/4 "
20–16	5/8 "	9/32 "
24–16	21/32 "	5/16

When drawings are made and go to the pattern shop with just the ordinary "f" marks on, the pattern maker has to ask his foreman how much finish to put on each place. By using a stamp, Table No. 5, and marked drawings f^1 it shows the pattern maker to put 1-32 finish in that place, f^2 means 1-16 finish, etc., and it also keeps pattern maker from putting on too much finish and making heavy castings.

TABLE NO. 5—PATTERN SHOP STAMP

NOTE

F—FINISH

$F_1 = \frac{1}{32}$" FINISH
$F_2 = \frac{1}{16}$" "
$F_3 = \frac{3}{32}$" "

$F_4 = \frac{1}{8}$" FINISH
$F_5 = \frac{5}{32}$" "
$F_6 = \frac{3}{16}$" "

CAUTION

READ ALL NOTES BEFORE STARTING WORK.
WORK MUST BE TO DECIMAL LIMITS.
ALLOWANCE OF .010 INCH EACH WAY ON FRACTIONAL DIMENSIONS. DO NOT SCALE DRAWINGS.

Among the New Books

THE MOTORIST'S GUIDE, published by the Berry Company, Kansas City, Mo., under the direction of the Automobile Club of Kansas City. 117 pages, paper cover, $2.

Comprising several tours out of Kansas City to points of interest throughout the state. The guide is fully illustrated by maps but lacks the descriptive matter generally given in a tour book. This might be said to rob the work of a certain charm, although it may be forgiven in view of the fact that the directions are complete and thorough.

BRAZING AND SOLDERING, by James F. Hobart, fifth edition, published by the Norman W. Henley Publishing Company, New York City. 51 pages, illustrated. Price 25 cents.

A manual on the art of brazing or soldering which of such size and binding that it can be conveniently slipped in the pocket. Formulas for the making of different solders and the flux to be used with each are given in a summary at the end of the book where they can be readily found when wanted. It should prove a useful book for apprentices or helpers not having the experience necessary to remember all the required formulas.

THE POLYTECHNIC ENGINEER, for 1912. Published annually by the undergraduates of the Polytechnic Institute of Brooklyn, under the auspices of the Polytechnic Institute Section of the American Society of Mechanical Engineers. 132 pages, 6 by 9 inches, illustrated. Cloth, $1.

Containing papers which are always of intense interest, owing to their timeliness, this annual work is always welcomed. Among the more interesting papers are: Testing and Manufacture of Smokeless Powders at the United States Naval Proving Ground, by John C. Olsen; Deflection Due to Shear, by Edward J. Squire; The Selection of Material for Machine Parts, by C. W. Gremple, and Problems in the Manufacture of Chemically Pure Acids, by C. W. Gremple. An outline of the course pursued at the Polytechnic Institute is also given, along with some interesting editorial notes and reports of the various students' technical societies.

Harking Back a Decade

What the Automobile Journals of 10 Years Ago Had to Say Concerning the Happenings of the Day

FROM *The Automobile and Motor Review*, June 28, 1902:

Some of the American automobile factories produce vehicles of various patterns, just as the large carriage factories turn out numerous styles. However, it is true that at present the different patterns of automobiles represent more nearly the work of different factories than do the different styles of carriages.

The muffler is one of the prominent features of the Oldsmobile, being the cause of the frequent comments passed concerning the quietness of running of the machine by a number of parties.

The recent stand of the Automobile Club of America against all road races threatens a cessation of these important events on this side of the ocean and similar efforts are being made in France, Switzerland and Germany, so that the road race may be considered as on trial for its life.—Editorial.

Recent transfers of farm properties in Nassau County on Long Island give to a group of wealthy automobile enthusiasts a continuous strip of land from Long Island City to the country home districts of Nassau and Suffolk counties. Talk of the building of a motor parkway is again in circulation.

W. K. Vanderbilt, Jr., David Wolfe Bishop, Foxhall Keene and Albert C. Bostwick will be the American representatives in the Paris-Vienna race scheduled for next week. There are 177 entries.

Impounding automobiles for various periods after their owners have been found guilty of speed law infractions has been suggested in New York. This might work out all right except that where a wealthy speedster owned several cars, one or more of them might be in the pound, but there would be nothing to prevent him from using others.

Suit for $25,000 damages has been filed by Everson Stout, of Indianapolis, Ind., in the Superior Court as the result of the accident that befell Mr. Stout last winter while a passenger in an electric car which tumbled from the incline at the automobile show and thereby smashed several exhibits besides injuring Mr. Stout.

The Steamobile Company of America has sold out to the Standard Roller Bearing Company and will retire permanently from the automobile manufacturing field.

Winton's Bullet to the Fore

ALEXANDER Winton expects to test his new racing machine, which he has named "Winton's Bullet," next week. He expects to get 80 miles an hour out of the new racer.

After a most successful period, both from a financial and non-financial point of view, the National Exhibition of Berlin, the forerunner of a much larger international show during the coming year, has closed its doors. Racing automobiles and two-seated voiturettes were scarce, the main lines being represented by comfortably sized cars almost exclusively.

The recent escape of the Humbert family of swindlers has resulted in much annoyance to automobile tourists in France. Ever since the disappearance of the much-sought family it has been the custom to halt every likely-looking automobile party and make the members prove their identity. Among the notables who have been searched so far are Prince Egon of Furstenberg, and three American parties.

Philadelphia is making a bid for space in the spotlight of publicity by considering the enactment of an ordinance to limit the speed of automobiles in the central part of the city to 5 miles an hour.

There are now more than 600 automobiles in California, of which 400 are operated in San Francisco. Gasoline and steam cars are made at the Golden Gate, but so far no electric automobiles.

A free school to familiarize horses with automobiles is about to be started at Kenosha, Wis. The feature of the curriculum will be a training track around which automobiles will be run for the instruction of the horses.

Arrangements are being made for a 1,000-mile race against time on Long Island. A French car equipped with water and gasoline tanks large enough to carry supplies for the whole distance, so that the wheels need never stop turning, will be used. No provision for replacing tires under the same conditions have been made.

A tax of 1 franc, or 19.3 cents, per quintal of 220.46 pounds on crude petroleum has been adopted by the French Chamber of Deputies. Heretofore the tax on petroleum has been $1.74 per quintal.

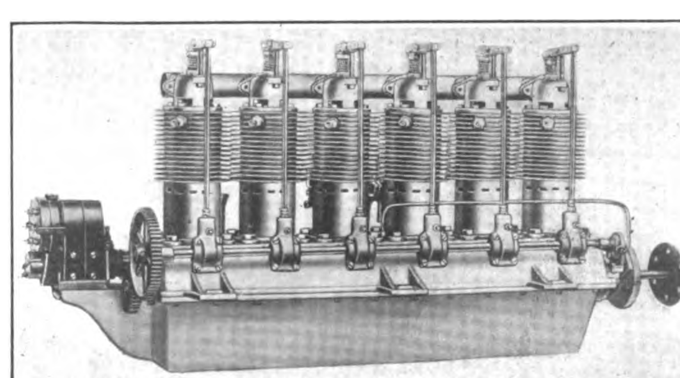
A Duryea three-wheeler made 3 miles from a flying start on a half-mile dirt track at Reading in 5:08, which is the best time on record in the United States for a gasoline vehicle on a circular track.

Cooling Water in Alcohol Motors—The consumption of cooling water is about the same for most of the small alcohol and benzine motors in the German market—namely, about a quart per horsepower hour. This consumption is about the same whether cooling is effected by evaporation or by water circulation, the former being the more simple of the two.

Decreasing Motor Compression—It is easy to decrease the compression of a motor. Place gaskets between the crankcase and the cylinder until the required decrease has been made. Fiber is the best material to use for these gaskets. It is not advisable to attempt to shave material off the tops of the pistons in an effort to reduce compression as the pistons are generally as thin as is compatible with safety, and to further reduce the thickness of the material is dangerous. It is not safe to shorten the connecting-rod either, for, when this is done, the angularity is increased so that there is danger of the connecting-rod striking the crankcase.

Light Motor with Concentric Valves

A new light motor which is especially adapted for aviation work has been brought out by R. O. Rubel, Jr., and Company, of Louisville, Ky. It is illustrated herewith. The most prominent features of the motor are its large concentric valves, situated in the head of the cylinder. Everything has been done to make the motor as light as possible, semi-steel cylinders being used and a solid vanadium steel crankshaft. As a special inducement the makers maintain an aviation field which the users of the motors may occupy while trying out their motors.



New type of light concentric valve motor

Synopsis of European Efforts for Reconciling Rapid and Automatic Mass-Production of Automobiles with Improvements in Accuracy of Dimensions and Durability —A Move Toward Larger Payloads for Omnibuses—Vibrating Shafts

MANUFACTURING METHODS.—The international struggle for supremacy in the economical fitness of manufacturing methods is working itself toward a keener edge than ever before. Realizing at last that the future in automobile manufacture belongs exclusively to those who learn to combine high quality with low cost of production, the leaders among European engineers are now turning their attention to the most fundamental requirements for reconciling rapid mass-production, which is necessary for economy, with a new standard of excellence in which the early adoption of advanced design is relegated to second or third place, while the durability and reliability of the finished product are safeguarded far better than they ever could be under the old system of depending mainly for accuracy in dimensions and the properties of the materials, upon the individual skill of specially trained workmen. The salient feature in the new movement, as it is cropping out in Europe, lies less in the adoption of the practice of designing and building new machinery specially for the production of the parts wanted for any new model of automobile which has been decided upon, than in the devising of special measuring instruments so nearly automatic in their action that they will secure accuracy in dimensions of parts and secure it cheaply, even when placed in the hands of the most ordinary workman and, furthermore, in highly simplified machinery for testing raw materials and finished parts for the physical properties required of them.

To Measure or to Compare—Which?

Just to what extent the American practice is gaining headway which consists in supplying each workman with inalterable samples of the one or two measurements which it is incumbent upon him to duplicate—these samples being produced in advance of all other manufacturing processes and with extraordinary care—does not appear from the articles on the subject which are published with some frequency of late in the technical periodicals of Europe. Perhaps this practice is looked upon as a self-evident extension of the jig-and-templet system which is known all over the industrial world as indispensable in the assembling departments, and the economic importance of its application to the primary production of parts on the machine tools, in the foundry and in the drop forge shop, has possibly not yet been fully recognized abroad. The mere fact that great stress is laid upon the perfecting of instruments, such as the "minimeter" partially described in THE AUTOMOBILE of May 2, by means of which the workman can make any one of a number of different measurements with great accuracy and speed, seems to indicate that specialization in the producing system is not yet being forced to the last notch and that the Europeans still prefer to keep open the chance of switching a machine tool from one job to another or shrink from the expense of providing new measurement-"normals" for every variation in design and dimensions. The limited home markets of Europe may account for the difference in policy, and a close analysis might also find a temperamental desire to keep ahead of America by a greater mobility in design and adoption of improvements.

With regard to the simpler methods introduced for the testing of materials, before and after machining and heat-treatment, mention was made in THE AUTOMOBILE of March 14 of the great favor now accorded the Brinell method for testing hardness and at the same time determining the tensile strength and the elastic limit by simple reference to a table based on certain fixed or nearly fixed relations between the figures expressing these properties and the hardness number (or rather density number, since the Brinell method does not give the mineralogical hardness but a property in which hardness and toughness both enter as factors). In the issues of Dec. 21, 1911, and Feb. 29, this year, brief descriptions were given of new machines for locating errors in the cut of gear teeth and of a rotary ram designed for shock-tests of materials and admitting of very quick decisions. On April 4 a machine for polishing test pieces was described.

In all of these innovations there is noticed a desire to emancipate the attainment of extreme accuracy—which is a paramount requirement if cheap and efficacious replacements shall take the place of expensive and yet unsatisfactory repairs in the long-time use of an automobile—as well as the safeguarding of the strength of materials from all question of individual skill among workmen, and this desire is coupled with a strong effort for saving time and risky reasoning in the departments of supervision and testing. Academic considerations are very plainly thrown to the winds, when, for example, in the Brinell test, the matter of the composition and hardness of the steel ball with which the imprints are made is left to the manufacturer supplying the machine and the balls, on the principle that wherever this testing machine is used for practical purposes the main object should be to establish comparative figures for the different materials under consideration rather than absolute figures which would hold good in comparison with other tests made in other places and with other machines. This inferiority of the Brinell method from a scientific standpoint—in not giving figures of the same universal validity as those obtained by the old laborious method of pulling standard test specimens—is disregarded in consideration of its practical advantages and its rapidity, as is also its acknowledged inapplicability to cast iron and case-hardened articles. A large number of uses remain for which it is industrially superior.

Brinell Conversion Formulas.

As in other similar cases, the movement for simplified testing apparatus owes its impetus largely to the initiative of a few individuals and concerns. Brinell designed his apparatus in 1900, submitting it to the Swedish Technological Society, and the Copenhagen engineering congress held in 1910 finally brought it

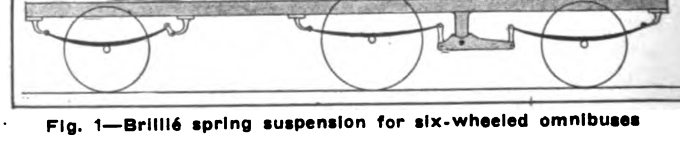


Fig. 1—Brillié spring suspension for six-wheeled omnibuses

prominently before the technical public. It is now manufactured not only by the Alpha company of Stockholm, but also by two German concerns, and the renowned automobile parts maker, the G. Derihon company of Loucin, Belgium, and Jeumont, France, manufactures a simplified model especially intended for automobile manufacturers, as well as for the company's own use. The tables compiled for facilitating the use of these machines are calculated on the basis of the formula:

$$H = \frac{P}{\frac{\pi \cdot D}{2}\left(D - \sqrt{D^2 - d^2}\right)}$$

in which H is the density number, D the diameter of the steel ball used for making the imprint in the test piece, in millimeters; d the diameter of the imprint, also in millimeters and fractions thereof, and P the pressure applied to D, in kilograms. By comparison with tensile tests it has been found that the tensile strength in kilograms per square millimeter is obtained from the density number by multiplying the latter with either 0.354 or 0.362 when the density number lies below 175, giving a working average of 0.358; but when the density number is higher it should be multiplied by a slightly lower coefficient, averaging 0.334.

Measuring Wearing Qualities

Among testing machines developed by the Derihon company there is also one for deciding quickly the wearing qualities of a material. (This also seems to be designed to give valuable pointers rather than absolute figures, inasmuch as neither the material of the pressure-disk employed in it nor the area of the rubbing-surface seems to be susceptible of ready variation.) A side view of this machine is shown in Fig. 2. The waterjacketed housing R is one-third filled with lubricating oil, and in it is mounted the disk O, which is made of an especially hard alloy and the circumference of which is exactly 1 meter, giving a circumferential velocity of 8 to 50 meters per second at 500 to 3,000 revolutions of the disk per minute. The test material is fitted into a prismatic guide piece V which holds it against the top of the disk, passing snugly through an opening in the top of the housing. The pressure is applied through the knife-edge lugs B on a lever fulcrumed at A and loaded at C by means of the weight P. Compensation for the weight of the lever itself—which otherwise would be a disturbing constant in all comparisons—is provided through another lever E whose fulcrum is at M, while the weight Q, suspended at F, applies the required lift by means of lugs D to the yoke G which receives the downward pressure of the other lever ABC by means of lugs B. The ratio of the lever arms AB and AC is as 1 to 12, and at L there is a knife-edge lug whose distance from B gives exactly a 10 times greater movement to this point of the lever than that to which the point B is subject when the test piece wears down under the abrasive action of the disk O. By means of the micrometer screw K, at the fixed point N of the machine, which admits of readings down to a 1/100 part of a millimeter, it is therefore possible to determine wear of the test piece within limits of 1/1,000 part of 1 millimeter. At the beginning of a test, the lever ABC is first placed horizontally, for which purpose the point A may be adjusted by the screw H. And the micrometer screw K is turned until an electric circuit, which is closed when L touches K, moves the hand of a galvanometer. After the end of the test the micrometer screw is turned down till the contact is again closed and the hand of the galvanometer again moves. By this arrangement the reading is made independent of the sensibilities of the operator. Thermometers admit of reading the temperature of the cooling water, and of the test-piece itself, while an odometer and a cyclometer measure the speed and the total number of revolutions involved in a test. The apparatus is driven by an electric motor and a voltammeter serves to check possible irregularities in the power, so that these may be taken into account if necessary.

Tests with this apparatus have demonstrated surprising variations in the wearing properties of steels whose chemical compositions were very similar and have, in the practice of the Derihon company, led, for example, to the adoption of a certain air-hardening method in the treatment of large bevel-gear crowns for automobiles, the method giving a minimum of deformation and wearing qualities almost equal to those obtained by casehardening of another chrome-nickel steel of lower carbon content, although its mineral hardness is considerably lower. —From *Der Motorwagen*, May 20.

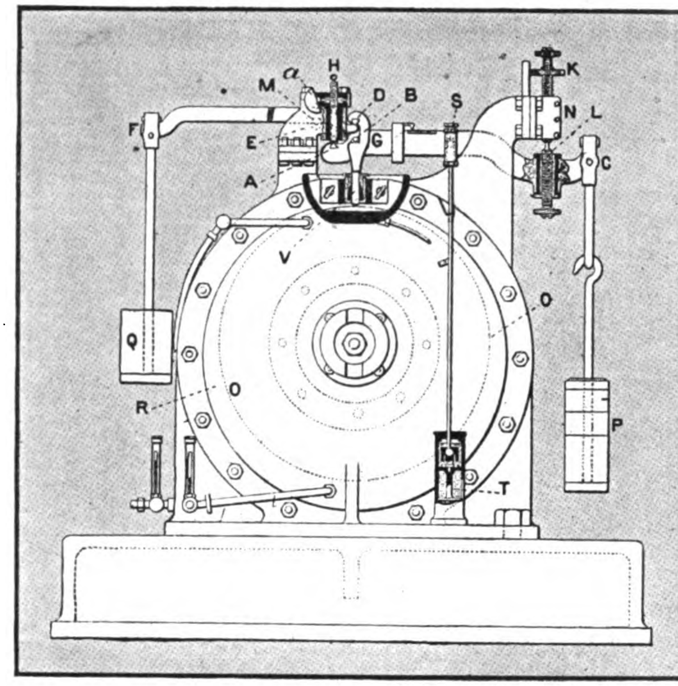

Fig. 2—Derihon machine for measuring wear of materials

—

Six-Wheel Omnibuses—The General Omnibus Company of Paris intends to place in circulation before long a small number of vehicles with three pairs of wheels of which the middle pair are to be drivers, while the steering will be done with both the front and rear pairs. The objects to be attained are increased carrying capacity, ability to turn in a small circle, and the avoidance of skidding, but the spring suspension of the three axles presents a problem which has not heretofore been satisfactorily solved. The system which will be tried out first is that which has been devised by Brillié for Schneider omnibuses. In this, it is only the two rear pairs of wheels whose spring suspensions are connected, while the front axle is independent. The front ends of the driving-wheel springs and the rear ends of the rear wheel springs are attached directly to the frame reaches, but the intermediate ends of these springs are shackled to the ends of a balancing lever which is secured horizontally under the frame reach free to oscillate around a fixed pivot. The two arms of this lever are of unequal length, however, the arm nearest the driving-wheel axle being about one-third the length of the other with the purpose of making the driving-wheels continue to carry the bulk of the load when they pass over an obstacle, or when the vehicle load is too far to the rear, as may easily happen with an omnibus. The accompanying side view, Fig. 1, shows the general plan of this system of suspension, which is considered the simplest yet devised. To facilitate the compensating action between the two axles, it is necessary to allow the wheel axles to turn in the spring clips or fastenings.—From *Omnia*, May 25.

—

Critical Speeds—Renewed experiments by German engineers show great irregularity in the periods of excessive vibration observed in connection with rotary shafts, indicating that the phenomenon, which is ascribed to rhythmic coincidence in periods of oscillation, must be obviated experimentally in each instance.

R-C-H 1913 Models

While No Radical Changes Have or the Body Design, Special Provide Highest Class of

Electric Lighting, Non-Skid Tires, Special Curtains, Auto- Cars Are Standard in This

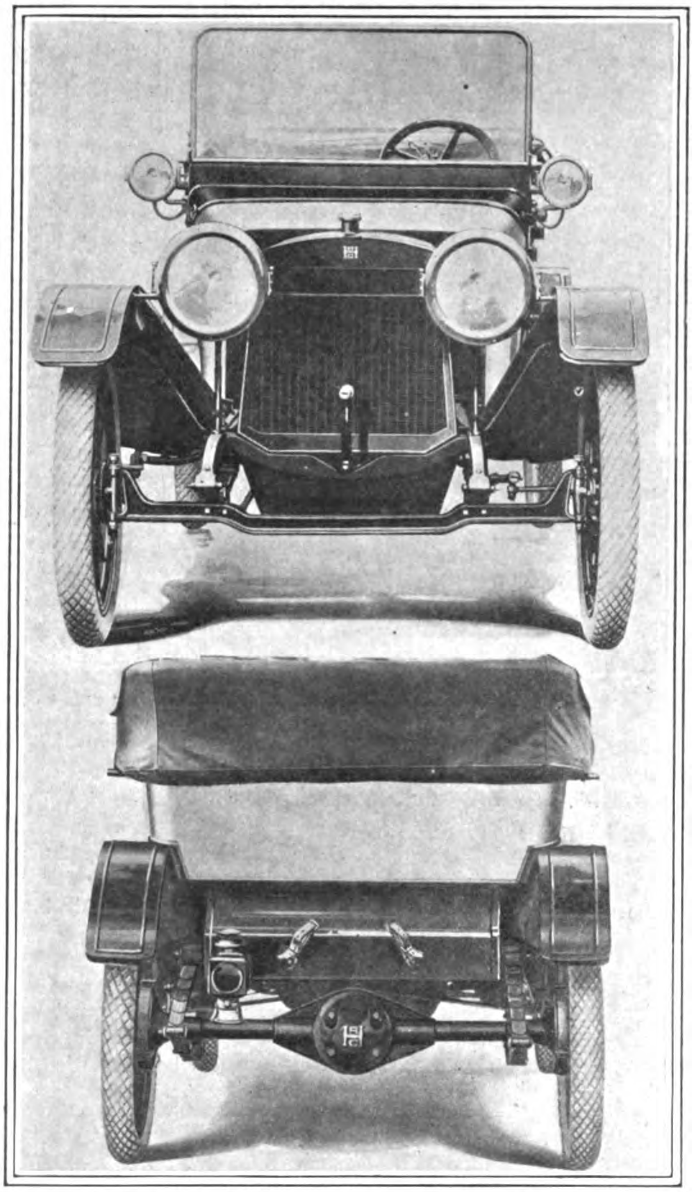

Fig. 1—Front and rear views of new R-C-H product

BELIEVING that full equipment will be the keynote for the coming year, the R-C-H Corporation has announced its models for 1913 with this as the talking point. Practically no changes have been made in motor, transmission or in body design, the car presenting the same general lines that characterized it when it first made its appearance in the motoring world less than a year ago.

The equipment of the new models will be most complete, consisting of non-skid tires on all four wheels, size 32 by 3 1-2 inches, electric lighting, Bosch magneto, Warner Auto-Meter, demountable rims, extra rim holders, Tally-ho horn, Jiffy side curtains, top and top-cover, windshield, rear-view mirror, robe-rail, tool-kit, tire-repair kit, jack, and pump. In so equipping this machine, R. C. Hupp is of the opinion that 1913 will be a season in which the convenience and comfort of the passenger and driver will be demanded. The fitting of electric lighting, non-skid tires, special curtains and Warner Auto-Meter to cars in the $900 class is an innovation for which the R-C-H is responsible.

The lamps on the new R-C-H cars are all of the bullet type, the headlights being 12 inches in diameter and fitted with parabolic lenses and 16-candlepower bulbs. The two side lamps are 6 inches in diameter, have the parabolic lenses also, and 4-candlepower incandescent globes, while the rear light measures 4 inches and carries a 2-candlepower bulb. On the headlights the parabola is set into the lamp body, permitting of easy access to the focusing device and facilitating the cleaning of the reflectors while they remain in place. The sockets for all the lamps are of Edison make. Current for the illumination is furnished by a

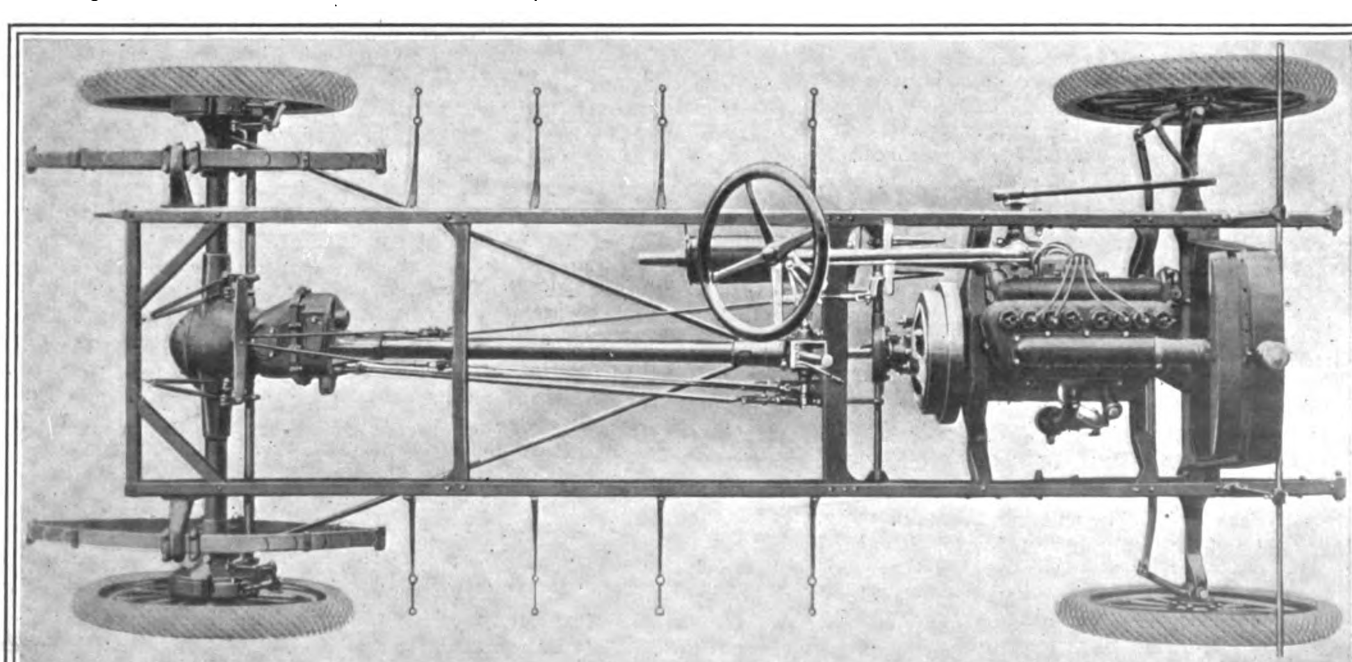

Fig. 2—Plan view of chassis, showing motor suspension, torque arrangements and principal control features

Now on the Market

Been Made in Motor, Transmission Efforts Have Been Made to Equipment Throughout

Meter and Other Adjuncts Peculiar to High-Priced Year's R-C-H Products

100-ampere storage battery which is carried within a case on the running board.

The only mechanical changes which the new car shows are the placing of a hand-throttle lever and spark lever on the steering column just below the wheel, and the addition of a hand-lever emergency brake in place of the former foot emergency brake. In the previous cars, two foot-brake pedals were used, one being the clutch and service brake combined, while the other operated the rear brake drums. The service brake operates on the transmission, as in the earlier model, but it is now a separate pedal, while the lever replaces the other brake pedal to bring the emergency hub brakes into play.

No change whatever has been made in the four-cylinder, monoblock motor, which has a long stroke of 5 inches and a bore of 3 1-4 inches. The rating is given at 25 horsepower. The crankshaft is mounted on two bearings—one at either end, which is in keeping with the general compact construction of the power plant. The motor is mounted in the frame of the car on the three-point suspension principle, there being a support at either side of the crankcase in front and one in the center in the rear. The valve rods and springs are all inclosed by an easily-removable cover-plate, while the timing gears are housed by plates fastening with cap screws. The Bosch high-tension magneto with single set of spark plugs is used, while the carbureter is of the latest B-D make.

The transmission, which is integral with the rear axle, is of the three-speed selective, sliding-gear type, the power being transmitted to it through a clutch of the dry plate form. The gearbox is mounted amidships of the frame, being supported by a cross member. The rear axle is semi-floating, the power reaching it through the agency of the amply-proportioned propeller shaft, which has one universal joint mounted back of the gearbox and which is inclosed in a torsion tube bolted to the rear axle. Two radius rods pass from the axle to the torsion tube for properly bracing the former, and for maintaining its correct alignment.

The rear springs are elliptic and they are mounted on swivel seats, taking much of the strain from the spring leaves. The front springs fasten directly to the I-beam, drop-forged front axle and they are of semi-elliptic construction.

The frame is of pressed steel, channel section, and it is braced at front, rear and center. The wheels are of artillery-type wooden construction, the designers, in keeping with most of the other American engineers, still adhering to them in place of the much-heralded wire types.

As to body design, this $900 touring car presents a decidedly foreign light-car appearance with its nearly square hood and

Cost of Work With Gasoline Motor Trucks

Louis Ruprecht, S.A.E., Calls Attention to the Methods of Obtaining Maximum Efficiency With Economy

Proper Routing—Improving the Load-Handling Facilities—Increasing Daily Work—Comparative Illustrations

THE graphic charts of actual costs of operation, and cost per ton-mile of work of motor trucks herewith shown, are merely a tabulation, for convenient reference and study, of trucking economy under varying conditions of loads and mileage.

They are intended more as a comparative study than a discussion of specific costs, but it is nevertheless in order to review the detailed figures used in arriving at the total costs for plotting curves.

Depreciation is figured at from 10 to 15 per cent., varying according to mileage and the size of the units, the tire value being deducted from the cost of the complete vehicles. One of the highest-priced types of truck is assumed in each case. The depreciation figures are based on experience with hundreds of this type of truck in use over a long period of years, in many instances longer than 10 years. It is only fair to say that the depreciation of the newer, more flexible models will be less than that of the older ones.

Drivers' wages on 1000-pound delivery wagons are taken at $2.75 per day, and on trucks, $3 to $4 per day according to size and length of day's work. Helper on trailer $1 per day. These figures in the case of a very large day's work might conservatively be figured a trifle higher.

Garage charges include only washing and storing of the vehicle: $240 to $300 per year according to size.

Tire cost is based on prices to user and 8,000 miles life as guaranteed by makers. The sizes figured are all in accordance with the makers' specifications based on weights of vehicles and loads, and therefore this large item of expense is figured conservatively.

Gasoline cost is taken at 11 cents per gallon. The price at this writing is a little higher, but only 3 to 6 1-2 miles per gallon is assumed as the performance according to size of vehicle.

Oil cost is taken at 30 cents per gallon; 50 to 125 miles per gallon according to size of vehicle.

Insurance: $100 to $250 per year according to size.

Repairs and replacements have been figured up to 3 cents per mile in the case of heavy trucks. This is based on extensive records.

Operating days per year have been taken uniformly at 300. This figure is a trifle high, particularly in cases where large daily mileages are made, although it leaves 65 working days and holidays for the upkeep of the equipment.

Comparing Costs of Hauling

ATTENTION is now called to the set of curves showing actual costs of hauling, expressed in dollars per year, for different sizes of units for varying average daily mileage. The ordinates indicate the average daily mileage from 10 to 100 and the abscissæ the total cost per 300-day year, all charges included. It so happens that on the basis of these figures the plotted costs are straight lines in every case. This indicates that the *total cost increases in constant ratio with the daily mileage.* These straight lines if continued to zero miles should indicate theoretically therefore the fixed and other charges against the equipment when idle, and in fact this is approximately the case; for it will be found that costs thus indicated at zero miles are practically the sum total of Depreciation, Interest, Part-Time Wages, Dead Storage, Insurance, Tire Depreciation, etc., actually chargeable against a vehicle temporarily out of commission.

This situation has suggested to me a convenient thumb-rule for figuring costs of operation, making unnecessary the use of this chart, as follows:

Cost per Day = "Fixed Charges" + (Miles per Day × Daily Increment in Cost).

Size	Fixed Charges	Increment Per Mile
1000-lb.	5.07	.0686
3-ton	5.33	.0860
5-ton	5.60	.1253
6-ton	6.00	.1540
7-ton	6.15	.1718
12½-ton train	7.40	.2070

For example, the cost of operating a 6-ton truck, all charges included, 45 miles per day, will be $6.00 + (.1540 × 45) = $12.93.

Costs per ton-mile can of course be derived similarly without reference to the second set of curves seen in Fig. 2; for

sweeping lines. The cowl has a low slope which is set off by the same design of windshield as marked the car on its début. The door handles are all inclosed, while, except for the battery box, the running boards are clear. The interior of the car has been designed to give the maximum of leg room consistent with the wheelbase of 110 inches. Seats are set at a comfortable angle, which the designers have deemed most restful for all occasions.

The two-passenger roadster is continued in two models, the standard and the EE types. The former, selling at $700, has gas head lamps, oil side and tail lights, 30 by 3-inch tires on clincher rims, gas generator, top and Jiffy curtains and horn as its regular equipment, while the EE model, which is to cost $750, has the same equipment except that a Prest-O-Lite tank takes the place of the generator and 32 by 3 1-2-inch tires on demountable rims are substituted for the 30 by 3-inch tire equipment. In all respects, these roadster models retain the mechanical construction as outlined for the touring car.

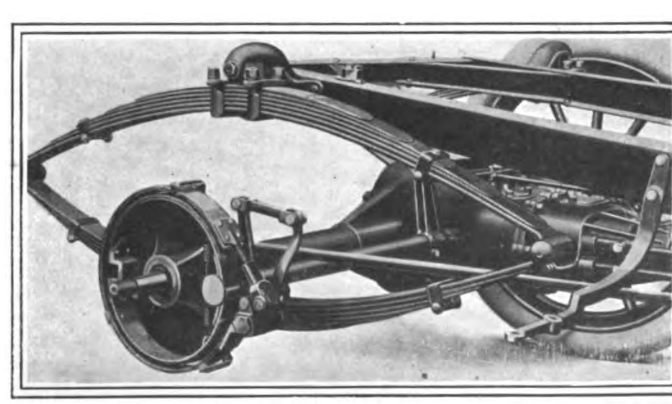

Fig. 6—R-C-H spring suspension and rear axle

these costs have been derived from the first set of curves.

In computing costs per ton-mile it is assumed that vehicles are fully loaded half the total daily distance traveled, or, what is equivalent, that vehicles carry half their rated capacity load the full distance. If they carry more than this the costs per ton-mile would be correspondingly reduced below the figures of the curves. For instance, with full load the entire distance, the cost per unit of work would be reduced almost one-half. I say "almost" because depreciation, repairs and renewals and fuel per loaded mile are somewhat greater than per dead mile.

A study of these curves reveals the large ***reduction in cost per unit of work by increasing daily performance*** as follows:

Increas'g daily mileage		Reduction in cost, per cent.			
From	To	3-ton	5-ton	7-ton	12½-ton train
10	20	44	44	44	44
20	30	25	20	21	20
30	40	17	17	12	11
40	50	14	14	10	10
50	60	10	8	8	9
60	70	7	6	4	5
70	100	12	8	11	10
40	100	38	32	30	30

In other words, increasing the daily work from 10 miles daily average to 20 reduces the cost per ton-mile, or per unit of work, 44 per cent. in all cases. Then increasing the daily work to 30 miles another reduction of 20 to 25 per cent. in cost per unit of work is effected. And increasing from 30 to 40 miles per day 11 to 17 per cent. reduction in cost is effected. Substantial gains in economy are made by further increase in daily mileage; increasing from 40 to 100 miles per day, for instance, effects a reduction of 30 to 38 per cent. in cost per unit of work.

Value of Proper Routing

THESE curves are impressive as indicating the economies to be effected by proper routing of vehicles for maximum daily work. The costs, as above mentioned (being based on loads one way only), can be very materially reduced if merchandise or material can also be carried over some of the "dead-mileage" assumed in these computations.

The approximate parallelism of the curves indicates that

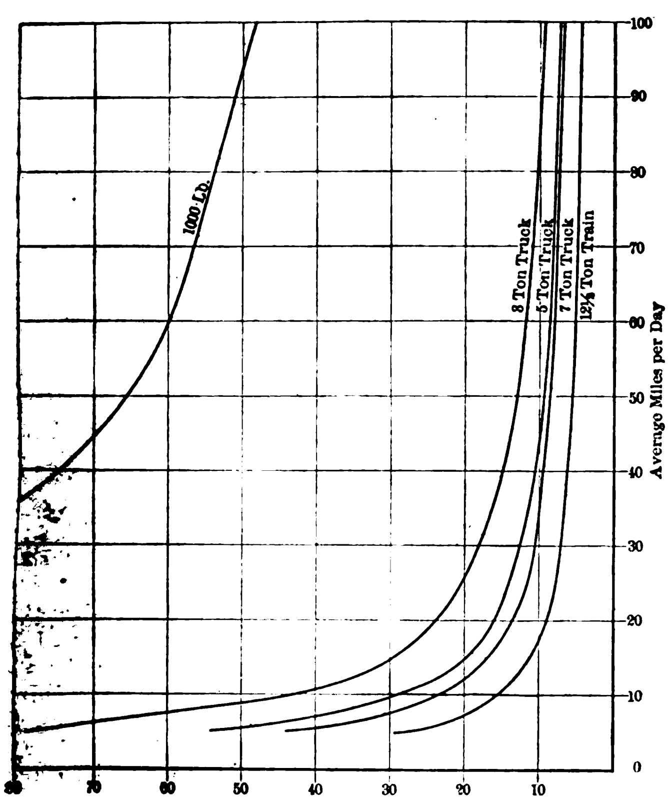

Fig. 2—Illustrating the comparative cost per ton mile for different sizes of units for varying daily mileages

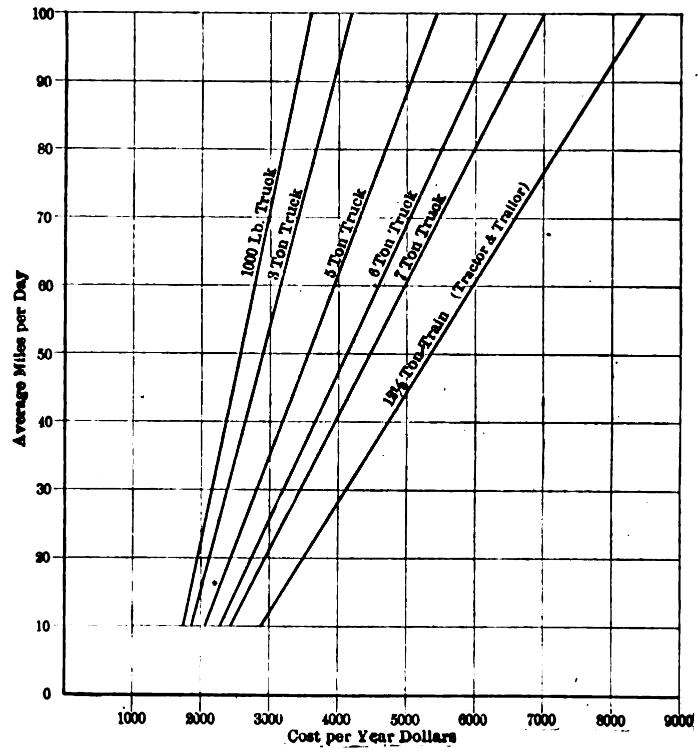

Fig. 1—Illustrating comparative actual hauling costs for different sizes of units for varying daily mileages

whether light trucks, heavy trucks, or trucks and trailers are employed, economy increases with increased daily mileage at about the same rate with all these sizes of units.

These curves are also of interest and assistance in studying the question of sizes of units to be used for any particular class of work. They show, for instance, that a 12 1-2-ton train (7-ton truck with 5 1-2-ton trailer), operating 70 miles per day and loaded only one way, will carry 1 ton of load 1 mile for 5 cents, whereas the same 1 ton carried 1 mile in smaller units operating 70 miles per day would cost 10 3-4 cents on 3-ton, 8 cents on 5-ton and 7 1-2 cents on 7-ton units; thus indicating the tremendous advantage of using large capacity units and trailers.

They show also, for instance, that the same economy, viz., 10 cents per ton-mile, is obtained by operating a 3-ton truck 84 miles, a 5-ton truck 44 miles, a 7-ton truck 35 miles, or a 12 1-2-ton train only 18 miles per day.

The proper routing of heavy transfer units and of lighter distributing units, the adoption of correct sizes of units for such service, or for pure straight haul service, the proper load handling facilities, are all problems which frequently require careful study, always with an eye to the practical conditions of each particular service, to obtain maximum efficiency and economy.

—

Carbureters for Kerosene—While designers in England and on the continent of Europe have lately turned out several carbureters intended for use with kerosene as a fuel or to be installed for emergency purposes or economy in cars also equipped with a gasoline carbureter, it is admitted that the fuel consumption with these devices is still so much larger than with the best gasoline carbureters that the economical advantage in using the cheaper fuel is wiped out. The difference in the consumption is due to the greater difficulty in vaporizing the kerosene and is not, as in the case of alcohol, an inherent shortcoming in the fuel; on the contrary kerosene exceeds gasoline in heat value, and correspondingly favorable results may be expected eventually if experiments are continued. This was the gist, for example, of a lecture delivered before the Institution of Automobile Engineers in London by Messrs. W. Morgan and Wood with special reference to a kerosene carbureter designed by G. Constantinesco of Rumania.—From *Auto-Technik*, May 24.

Motor Overheats Badly; Does Not Believe in Water Jackets; Minimum Fuel Consumption Under Different Circumstances; Repairing Oakland Clutch; Care of Locomobile Low-Tension Ignition System; How to Reach the Cadillaqua from Wheeling

Regards His Case as Hopeless

EDITOR THE AUTOMOBILE:—I have a Flanders 20, two-speed gearset. It has been overhauled, the cylinders cleaned and the crankcase has been cleaned out. It has a 4-inch spark advance at most. I have tried all kinds of carbureter adjustments and all kinds of timing. I have polished the combustion chamber; tried all kinds of lubrication and lubricants; put on air valve; ground the eight poppet valves and have done all that I know or ever heard of.

The motor will heat up to boiling point in running 1-2 mile and loses power after it has run about 10 minutes in spite of all my care. At first it works finely and while cold pulls strongly. What should I do?

Chapanoke, N. C. JOSEPH TOWE.

—You have apparently overlooked the very first thing that should have been done. That is to clean out the radiator. A scale gathers on the radiator that will cut down its efficiency to a remarkable degree unless cleaned out. If the water is hard, as it is very likely to be in North Carolina, the deposit of lime would impair the radiator efficiency so much that the trouble you encounter is only to be expected. The cure is as follows: Secure a large wash boiler and put in about 10 gallons of water. Bring the water to a boil and add twenty handfuls of washing soda. Stir this up until it is well dissolved and allow it to drain through the radiator. When there is just enough left in the boiler to fill the radiator, fill it up. Keep the drain cock closed, put on the cap and start the motor. Allow it to run for 2 or 3 minutes; stop it and drain out the water. Flush out, with rain water if possible, or, if not, use the purest water you can get. After this, refill the radiator and there should be an improvement in the running.

You do not mention if the water pump is working satisfactorily. Examine this also. Other causes for your trouble are: bad valve timing, magneto timing, dragging brakes and bad oil feed. In connection with the latter it would be advisable to fill the crankcase until the motor smokes and then see if it runs without heating. If it does you have found your trouble.

Criticises Engineering Practice

Editor THE AUTOMOBILE:—I would like to enter upon a discussion with your readers upon some points which may be quite a matter of course, but which are not clear to me. For what reason are means for cooling gas engine cylinders resorted to? What sound reason is there for their present use when it appears that an engine will work better without them? To be more specific: My engine is conventional, being of the horizontal type designed to run on city gas. It is waterjacketed, but I have run it for 2 months without any water; and, what is more, I intend putting an asbestos jacket around the cylinder since it is not hot enough to suit me.

To come back to the question: Why a waterjacket? Is not the engine a heat engine? Is not the driving power the difference in potential between the heat at the time of the explosion and the surrounding air? Why lower the temperature of the cylinder? There must be a reason for the present use of the waterjacket, since engineers persist in keeping it, but we must admit that fashion dominates engineering as much as women's hats. Still, I believe that running an engine as above stated brings up a question which is worthy of serious consideration from the designers. What is the answer of the technical fraternity?

The present temperature of the motor I cannot state. It is sufficient to melt babbitt and yet I am tempted to believe that I can nearly double it. The oiling is very good, less oil than usual being required. The compression is excellent, being probably about 80 pounds, and what I use for fuel is immaterial. It has been stated by authorities that an increase in efficiency is practically impossible in a gas engine. Does not the above refute this? The losses in the waterjacket have been given as a result of tests not less than 33 per cent; would they be in this case?

I have also noted that the highest compression pressure is obtained at the rear dead center only when running at very low speed and that at all other times the compression maximum wave is considerably behind the piston speed. This would indicate that all our high-speed engines at the present day are radically wrong. What have our designers to say to that? Will some of them be good enough to verify my statement? I think it is a discussion of great value to the industry. One more: Some makers claim that they can inject water into the cylinder for cooling purposes, this water forming steam; I have been unable to duplicate this: it will leave as water. What is the answer?

New York City. P. G. TISMER.

Speed Affects Fuel Consumption

Editor THE AUTOMOBILE:—Will you answer the following questions and clear up a controversy between our local automobile men?

(1) Given a 20-mile stretch of level road, will an automobile consume more gasoline if driven over it in 55 minutes than if driven over it in 30 minutes?

(2) Given a stretch of road of the same length in hilly country, uphill and down being about equally divided, so that it would be possible to coast part of the time, would more gasoline be consumed in 55 minutes than in 30 minutes?

The latter question, you will see, brings in the question whether the open throttle, as would be required for quick work up and down hill, would be offset by the shutting of the throttle when coasting down the hills.

Bridgeton, N. S. W. A. WARREN.

(1) Assuming that the carbureter on the car is adjusted for ordinary touring, its speed of best economy would be about 25 miles an hour, as was explained in THE AUTOMOBILE of June 27, page 1487. If the distance was covered in 55 minutes, the speed would be about 22 miles an hour, which is very close to this; while 30 minutes would mean a speed of 40 miles an hour. The best economy would be obtained in the 55-minute run.

(2) This question resolves itself simply to one of climbing 10 miles of hill. The best economy would be secured when the car

was allowed to coast down the hills with the motor stopped; that is, with the switch turned off and clutch out. You do not state whether the hills can be taken on high gear. If they can by rushing them at the bottom this would be the most economical way. The slope of the hills would affect this, as if they were steep the rushing of the next up-hill could be done by simply allowing the car to coast with the brakes off. In other words, the most economical speed would be that in which the least gear-changing is done, and considering the amount of rushing that would have to be done, the speed would probably be nearer that in which the course is covered in 30 minutes.

Care of a Low-Tension System

Editor THE AUTOMOBILE:—I have an old Locomobile car with a low-tension ignition system. I have just bought this car second-hand and would like to have the ignition system explained to me.

Paducah, Ky. READER.

—The accompanying illustration showns the system so clearly that very little explanation is needed. The upper end of the tappet rod T is hooked onto the end of the hammer lever H. As the tappet rod is given vertical motion by one of the cams on the camshaft C-C, a hammer comes in contact with the anvil A and stays there until the cam has reached such a position that the tappet rod suddenly falls, causing the hammer to separate sharply from the anvil and the spark to occur. This action is assisted by a strong inclosed spring S1 at the bottom of the tappet rod. It will be noticed that there is a spring S at the top of the tappet rod, the purpose of which is to maintain enough pressure on the end of the hammer lever to keep the electrode in contact until it is time for the break to occur.

The hammer, or moving electrode, has a conical bearing through the igniter plate so that the pressure inside the cylinder forces the hammer bearing tightly against its conical seat and prevents any escape of gas at this point. The igniter plug, or anvil, is the fixed electrode and is made a solid unit. It has a taper fit through the igniter plate, being drawn up and held on the outside by a hexagonal nut. The insulation of the anvil consists of mica, compressed and highly polished, knife-blade switches K form electrical contact between an insulated bus-bar B B and the anvils, the copper jaws of the switches being secured to the insulated portion of the anvils outside the cylinders.

The important things to consider in the maintenance of the ignition system are the igniters. If an unnecessary amount of lubricating oil is continually fed to the motor the ignition will eventually become foul and irregular operation, or even a short-circuit, may result. Therefore do not give the motor too much oil and make it a point when the valve covers have been removed to inspect the igniters and clean them if they are foul. If suitable oil is fed to the motor in the proper quantity, not only will the lubrication be thoroughly adequate, but the igniters will be clean and thus will not require much attention.

When the car is inspected, it is well to look over the wiring and see that all terminals are in proper order and that the knife-blade switches K are making proper contact with the copper jaws A. The latter should be kept clean and pinched together. Keep the hard-rubber handles on top of the switches screwed down tightly.

Wants S. A. E. Horsepower Rating

Editor THE AUTOMOBILE:—Can you give me the S. A. E. rating of the new Hupmobile 32 which has a bore of 3 1-4 inches and a stroke of 5 1-2 inches?

Hop Bottom, Pa. S. E. MILLER.

—The S. A. E. rating of this car is 16.9 according to the formula $\frac{D^2N}{2.5}$, in which D is the cylinder bore; N the number of cylinders and 2.5 a constant which approximates the 2.489 evolved by the S. A. E. This constant takes into consideration an average piston speed of 1,000 feet per minute and an engine efficiency of 75 per cent. between indicated and brake horsepower. On a long-stroke motor this rating underestimates the power.

To Cadillaqua by Automobile

Editor THE AUTOMOBILE:—Several of my motoring friends and myself intend to make the tour to Detroit from Wheeling to see the Cadillaqua, which is to be held there in July. I understand that this will be the gathering place for numerous motorists from all parts of the country. In consideration of this I would like a synopsis of the route. Can THE AUTOMOBILE help me in this?

Wheeling, W. Va. G. A. TUCK.

—The first part of the route takes you from Wheeling to Canton; the distance is 85.8 miles, and the roads, which traverse through hilly country and abound in beautiful scenery, are for the most part of good macadam. As far as Steubenville they are of natural dirt and very good in dry weather.

Set your indicator at zero at Twelfth and Market streets, Wheeling. Start on North Market street with trolley and at Tenth street turn to left, crossing the long stone toll bridge, after which proceed to diagonal four-corners, then over the long iron toll bridge into Bridgeport. Follow trolley out Zane street, then turn under trolley and cross railroad tracks at reading of 4.6 miles. At the end of the road turn along railroad tracks, passing beneath them and crossing trolley at 4.9 miles. Taking the right road and leaving the toll gate at the left, and passing again

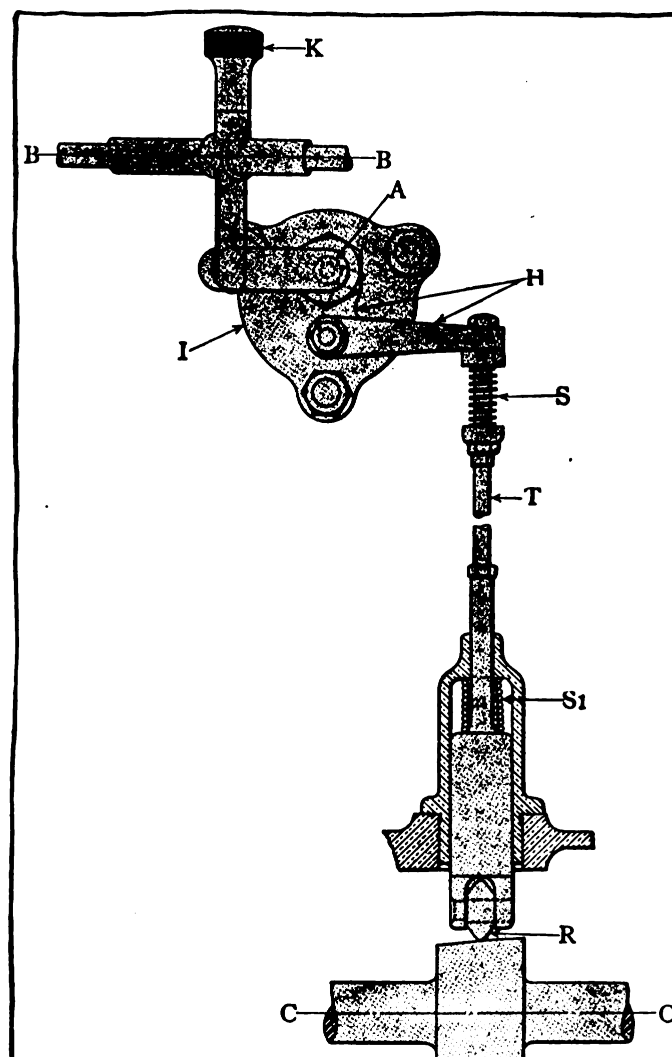

Fig. 1—Illustrating the low-tension ignition system used on Locomobile cars previous to the year 1911

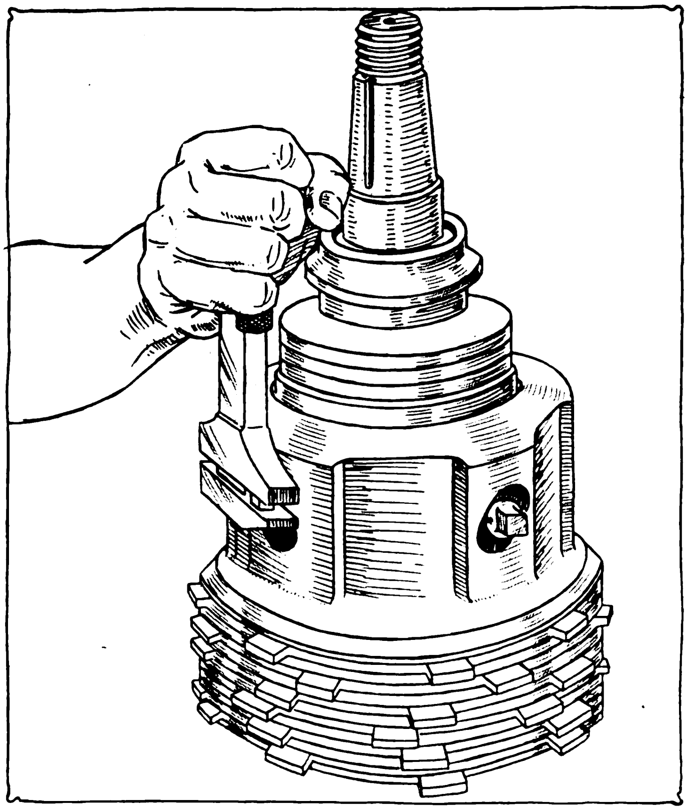

Fig. 2—Taking down the Oakland multiple-disk clutch; first step in operation

under the railroad at 5.5 miles, crossing it 5.6, turn along the river bank and follow it to 8.7 miles, where you turn left with the road. At 8.9 take right road, turning across the tracks at 9.5 and at the end of the road turn left into Rayland. Cross the long iron bridge, taking first right road at 10.4. At 10.9 take the right road just before the upgrade, turning to the right under the railroad and then immediately to the left until you turn to the right again at 11.1, after which cross the railroad, passing through Warrentown.

Follow the left road, turning left at 11.5, passing along the river bank and turning right at 13.2. Turn left with road after crossing one railroad and running under another, then turn sharp right at 13.6 and run along tracks. Follow lines of main travel through Brilliant and then along trolley to Steubenville. Out Market street through Wintersville, Richmond, along line of main travel through East Springfield, Amsterdam, Harlem, Carrolton, New Harrisburg, straight through Morges Corners, Magnolia, Industry and with trolley into Canton.

The road from Akron to Elyria is macadam almost all the way. It is easy to follow and takes in a distance of 41.6 miles. Start west out Market street with trolley, pass through Smith's Corners, Medina, Mallet Creek, Erhart and then straight through to Grafton, picking up the trolley to Elyria. Route is now from Elyria to Toledo on good gravel and stone roads. Pass out Middle avenue passing City Hall running into College avenue, Oberlin. Go straight on through Townsend, following Townsend avenue to Main street and thence to Norwalk. Through on West Main street to Monroeville and out Monroe street to Bellevue, following lines of main travel through Clyde, Fremont and Woodville, being careful not to take Fort Wayne route here. Follow signs and local direction into Toledo. From Toledo to Detroit there are two routes. The shorter road is bad, so the longer is here given. The distance is 76.3 miles over gravel and stone roads. Leave Toledo by going north on Madison avenue, then out Collinswood avenue, through Detroit avenue, keeping straight ahead where trolley leaves to the left, and pass under railroad. After striking Erie pick up trolley and follow through La Salle, Monroe and leaving it for road through Old Port. Pick up trolley again at Trenton and following along brick pavement to Wyandotte and Ford City. Then follow trolley line straight into Detroit.

Trouble with Multiple-Disk

Editor The Automobile:—I am having trouble with the multiple-disk clutch on my Oakland 30 runabout. It slips. Can The Automobile tell me how this can be overcome?

It seems that when I put kerosene in the housing, the clutch will grab severely, if I give it oil it slips and if I do not oil it I am afraid it will wear. Have tried several grades of good oil with the same result. Clutch spring is down to last notch.

Muscatine, Iowa. C. E. Graetner.

—In the first place, it is important that you should know that there is a passage from the gearset housing to the clutch through which the lubricant is free to pass. The grade of oil in the clutch and gearset should therefore be the same. The best lubricant to use is a medium grade of cylinder oil.

To cure the slipping and grabbing troubles, disassemble the clutch by removing the screws shown in Fig. 2. The clutch can then be taken apart by lifting the various units off the shaft. Be careful not to separate the plates. Keep them in one pile in the same order in which they were taken off. The clutch collar is placed in a vise and the face between the jaw is filed down so that the collar fits tightly against the clutch sleeve support. This is the part against which the collar illustrated in Fig. 4 fits. After having filed this down for some distance, slip the collar over the shaft and see how far it goes down. If there is not gap between the collar and the sleeve support it will be right. In order to make this fit tightly, it may be necessary to file down the boss on the shaft. This can be determined after an attempt is made to close the gap between the collar and the sleeve support by filing as indicated in Fig. 4.

This gap may be closed by other methods. The shaft itself can be turned down so that the collar will slip down further. This requires an extensive machine shop to carry it out, as does a third method which consists in counter-boring to a greater depth the center of the clutch collar.

It would probably be advisable for you to also cut off two or three turns in the clutch spring. These should be cut from the front end of the spring and this should then be securely refastened. This puts a greatly added tension on the spring and will stop slipping tendencies to a great degree.

Finally, before reassembling the clutch, take the top plate and the lowest plate. These are both brass. Slot them with a hacksaw as shown in Fig. 3. This will permit the oil to pass

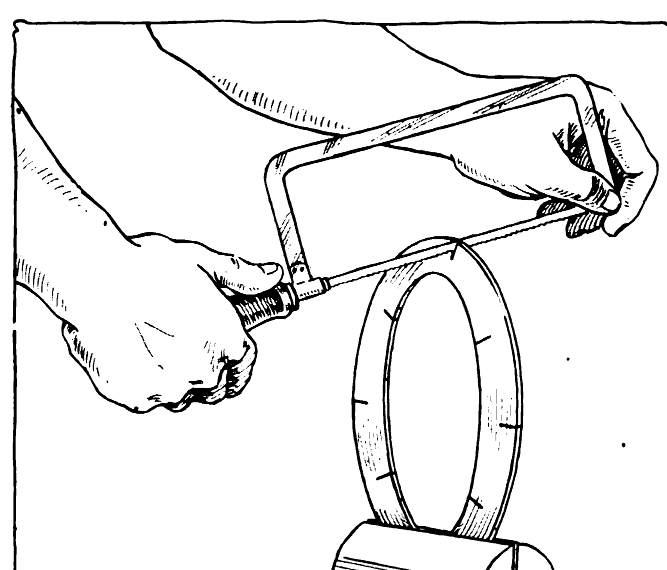

Fig. 3—Cutting the outside brass ring to permit of a flow of oil through clutch

freely through the clutch. If these directions are closely followed out the clutch may be put in prime condition and the repair will be practically permanent.

Constructing a Racing Motor

Editor THE AUTOMOBILE:—I wish to have further information regarding questions answered by you in the issue of May 23.

(1) The four and six-cylinder motors I am constructing have a bore of 4 5-32 inches and a stroke of 5 1-2 inches. Is this a good ratio for racing purposes?

(2) The valves have a diameter of 2 3-16 inches, opening with a lift of 7 1-6 inch. Is this opening large enough or too large, and is the lift high enough or too high?

(3) The cams are made to time the motor with inlet to open 15 degrees past top dead center and close 35 degrees past bottom center. The exhaust opens 52 degrees before bottom dead center and closes 5 degrees past upper dead center. Would you consider this timing right, considering the valve opening and lift? If not, state how many degrees different from any of the above you would recommend, as you say that quite a few motors overlap the valves; that is, have the intake open about center and the exhaust 10 degrees past, therefore having an overlap of 10 degrees. Also note that some motors close their inlets as late as 60 degrees after bottom dead center and open their exhaust before the bottom center. Would there be any advantage in opening the exhaust earlier, closing the inlet later and overlapping the inlet after the exhaust?

(4) Lubrication is by splash. The oil being fed to the trough and then scooped up by the connecting-rod as it passes on each, and under these conditions, would oil holes in the pistons be advantageous? If so, why?

(5) The flywheel with the clutch when finished weighed 113 pounds. It is 18 inches in diameter, and is fitted with aluminum cone, leather faced. Is this too much weight for either the four- or six-cylinder; if so, state what each should be. I am cutting the four-cylinder 5 pounds and the six-cylinder 10 pounds from the 113-pound weight, leaving the diameter the same.

(6) The four-cylinder car will weigh 2,350 pounds and the six-cylinder 2,750 pounds. I figure 32-inch wheels for the four-cylinder with 4-inch tires and 34-inch wheels with 4 1-2-inch tires for the six-cylinder one. Would you consider this right?

(7) The length of the connecting-rods is 10 3-4 inches from center to center. This, I understand, is a little shorter than average practice. But I have not room in the base for a longer one. Is it any disadvantage? The car I built worked satisfactorily on the road with these rods.

(8) The compression is 85 pounds, which I consider high and should be an advantage. If not right, should it be higher or lower?

(9) How fast should these engines turn over to be considered a good, safe speed for racing so that I can determine the gear ratio suited to the speed desired?

(10) Are cast-iron flywheels safe for high speeds, and at how many revolutions do they reach their limit of safety? Should I use a cast-steel flywheel, and how much would this increase the safety limit?

York, Pa. J. PIERCE.

—(1) According to your figures you would have a bore-stroke ratio of 1.132, which would be very satisfactory for racing purposes. The piston speed in this case at 2,000 revolutions per minute would be 1,833 feet per minute, which is common on racing cars.

(2) Your valve dimensions are good, but a lift of 1-2 inch would be better, remembering the short time for gas flow.

(3) The valve timing is largely a matter of cam shape in a racing car. Square cams should be used in order to give the valves a quick opening and closing, and it would be well to increase the strength of the valve springs slightly so as to make the action more positive. That is to obviate any danger of the follower not having speed enough to follow the cam. An increase of 5 pounds to the inch compression would make the springs about right. The timing for a racing car is largely a matter of personal opinion. Expert opinion, however, seems to run along the following lines: In terms of piston travel, inlet should open 1-8 inch after top dead center and close 1-4 inch above bottom dead center. Exhaust open 1-4 inch above bottom dead center and close 1-4 inch after top center, giving the inlet opening a lead of 1-8 inch over exhaust closing.

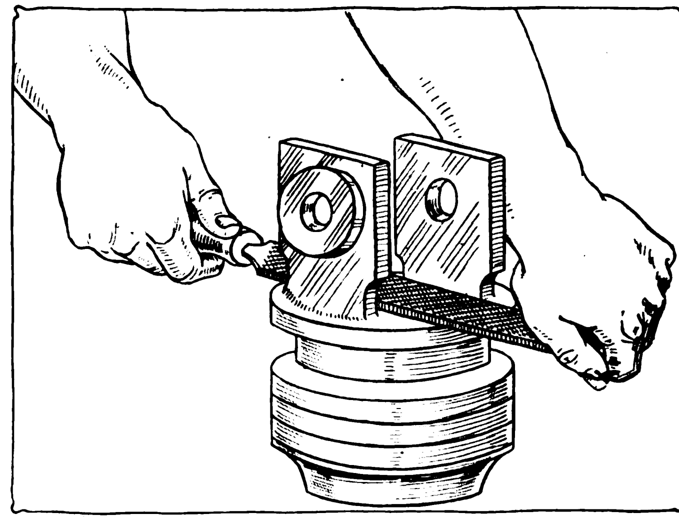

Fig. 4—Filing clutch collar to make it fit tightly against sleeve support

(4) Try motor without oil holes in piston. If it smokes cut them in so that oil will not be sucked into the combustion space, the idea being that only the oil above the holes could be sucked into the combustion space past the piston on the suction stroke, the air being sucked up from the crankcase through these holes instead of around the pistons.

(5) Flywheel can be cut down in weight to 90 pounds on the four-cylinder motor and 110 pounds on the six-cylinder. In each case the diameter would be, with these weights, 22 inches. With the diameter 18 inches, as you have it, the weights you suggest would be all right.

(6) Wheels, weight and tire sizes are correct.

(7) The connecting-rods are too short. This puts too much side thrust on the pistons and cuts down the efficiency of the motor on account of the added friction and angularity. The correct length would be 14 inches with a stroke of 5 1-2 inches.

(8) The compression could be made higher in a racing car, where every ounce of power is needed. From 90 to 95 pounds would be all right with a high-speed motor; 90 would give very satisfactory results all around.

(9) Two thousand revolutions per minute is good; 2,500 is the outside limit; 2,000 revolutions per minute would give you a piston speed of 1,833 feet per minute, which is as high as you will be able to go. To get this, all moving parts must be of the best material, light but strong.

(10) Use a steel flywheel. Cast iron is safe for all ordinary speeds unless there is a blowhole in the casting. A bubble may not be found by inspection, but would evidence itself by allowing the flywheel to burst at high speeds. The speed at which the flywheel will burst is that at which the centrifugal force equals the tensile strength. This depends on the weight, diameter and speed of the flywheel and is easily figured.

[THE AUTOMOBILE is holding a few queries and communications which have been received unsigned. If a correspondent does not wish his name published it is merely necessary to state this fact in the letter and a nom de plume will be substituted. As an evidence of good faith, however, it is required that all communications be signed. Those which have been received up to date will be held until the identity of the sender is known. All communications will be answered strictly in the order in which they are received.—EDITOR.]

New Reciprocating Sleeve Valve Motor

Inventor Brings Out Novel Engine with Exterior Valves Driven by Vertical Shafts and Connecting-Rods

Accessibility, Ease of Lubrication and Low Working Temperature the Chief Claims

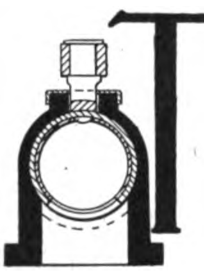

Fig. 1—Cross-section of valve

THAT inventors are still hard at work evolving new and original ideas on the sleeve valve motor is well illustrated by the latest development in this field which has been brought out by Denis P. J. Burguieres, a New Orleans sugar manufacturer, who has made himself known in that field by a number of useful inventions in sugar machinery. The distinguishing feature of this motor is that the sleeve valve is distinct and separate from the rest of the motor, thereby allowing the working parts to be operated at a lower temperature than if they were in closer proximity to the heat of the combustion chamber. In appearance, the valve is a long cylinder. Each cylinder is about the length of a block of two motor cylinders. There are four of these for a four-cylinder motor, two for each pair of cylinders, one on the exhaust side and the other on the intake side. Outside of the valves and their driving mechanism, there are no departures from standard practice in motor construction.

The valve consists of three main parts, a casing, an inner sleeve and an outer sleeve. The casing is attached to the outside of the motor cylinder as shown in the plan view, Fig. 4. The inner and outer sleeves are the two cylinders shown in the same illustration, the slotted sleeve being the inner or stationary sleeve, while the other sleeve, the lower in the illustration, moves with a reciprocating motion between the casing and the inner sleeve. The ports in the casing of the valve register with the ports in the cylinder so that there is always communication between these two. The port on the inner or stationary sleeve also registers with the cylinder and casing openings so that, were not the intermediate, or moving, sleeve between the inner sleeve and the casing there would be a free passage from the motor cylinder into the valve passage. The intermediate or sliding sleeve is also slotted, as may be seen in Fig. 4. It is shorter than the stationary sleeve and is therefore capable of a reciprocating motion. When the port in the center, or moving, sleeve registers with the openings in the casing and inner sleeve, the gas has a free flow from the center out into the valve passage and to the exhaust manifold.

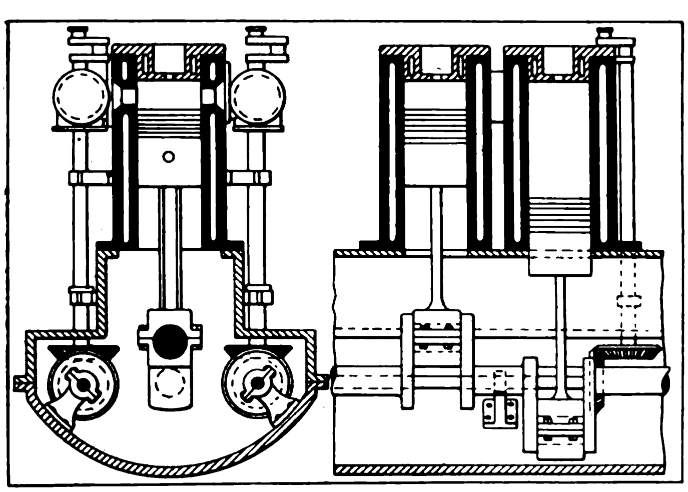

Fig. 2—Transverse and longitudinal section through motor

There is no possibility for leakage of compression past the sleeves for two reasons. In the first place, the gas, in order to escape from the cylinder when the ports are not in line, would have to pass between the sliding or center sleeve and the casing through the port in the center sleeve and then, to get through the opening in the inner sleeve, would have to come back between the inner and center sleeves to the opening in the latter. The natural inclination of the gas is against following a tortuous passage of this description so that there should be no leakage. Balance is secured by an annular fillet which passes around the interior of the casing. This fillet is filled with the gas at the time of exhaust and is intended to maintain an equal pressure all around the sleeves. Balance has been found to be one of the troubles which beset the rotary valve makers who mount their valves in much the same way, but who depend on a rotating motion in place of the reciprocating motion suggested in a motor of this type.

The drive is effected in a manner new to sleeve valve motors. A study of Figs. 2, 3 and 4 will show how this is carried out. Two shafts run the length of the crankcase, as shown in Fig. 2, one on either side. These are driven directly off the crankshaft by spiral gearing or any other method which may be desired by the manufacturer. From the center of this shaft between the two center cylinders a vertical shaft is carried up to the top of the motor terminating in a crank, which may be seen in Figs. 2, 3 and 4. Upon these two cranks are mounted a pair of connecting-rods, one for each valve. A slot is made in the casing so that the drive may be communicated to the center sliding sleeve and, to prevent a leak through the connection of the connecting-rods and the center sleeves, a cover is put over the slots. The cover slides in a guide along the top of the casing, making a neat and compact joint with little frictional loss and having but little weight.

Lubrication and Cooling Systems

Lubrication of the sleeve valve is taken care of by grease cups. In Fig. 1 the method employed in mounting these is shown. The cup is filled with light grease and is of the common compression type. The passage of the lubricant is through the opening in the casing and down on to the reciprocating sleeve. The oil is distributed about this sleeve by the grooves or ducts depicted in Fig. 4. By the action of these ducts and the reciprocating motion of the sleeve itself the oil is spread over the surface of the metal and the required film of lubricant is formed. There is practically no leakage of lubricant as the end caps of the cylindrical casing fit tightly against the ends of the stationary spring sleeve, Fig. 3. This tightness of the ends fills the two purposes of preventing leakage of gas or oil and at the same time prevents any endwise movement of the stationary sleeve. This method renders the lubrication of the sleeve altogether independent of the regular lubricating system of the motor. If desired, however, this could be departed from and it would seem that it would be an advantage in the case of a motor with a force-feed system to run a lead directly to the sleeve valve, making this part of the lubrication positive and independent of the driver's forgetfulness to turn down the grease cup.

Cooling the valve would depend upon its position. Should it be on the side of the motor, as shown in the accompanying illustrations, it would seem that cooling ribs at least on the casing would be an advantage or if brought in closer to the cylinder a waterjacket could be easily run around the casing. Expansion of the cylinders should not destroy the fit as the inner sleeve is sprung into the reciprocating sleeve by compressing it against the slot which runs its entire length. This spring action should com pensate for wear as well as for expansion. The method of cooling, however, would depend entirely on the position of the valves, which are of such construction that they can be placed almost anywhere the designer chooses to put them.

The claims made by the inventor are principally in the form of claiming the superiority of the outside sleeve motor over the inside sleeve type in that greater accessibility is secured, lubrication is simpler, on account of the position of the sleeves, and the fact that they work at a lower temperature than those having inside sleeves. It is also claimed that the moving parts are fewer and hence frictional losses are less. A fact which is of special significance is that the inventor claims fewer parts by half than are used in the construction of a poppet valve motor. This has been the tendency in all the latter designs of sleeve and rotary valve motor. The cutting down of the number of parts is drawing attention after years of insistance on the part of manufacturers for a simpler motor.

High Efficiency and Accessibility

The efficiency of the motor is claimed to be as high as that of any of the motors of the sliding sleeve type and a gain might be expected from the fact that the sleeves are of smaller diameter and hence give less chance for losses of power through the friction caused by the expansion of the sleeves. The advantages which are set forth above, it is claimed, would also tend to reduce power losses and to render the motor more efficient.

Repairs on the sleeves are declared to be more easily made than on the inside sleeve type because all that is necessary to disassemble the sleeves is the removal of the two end covers which are simply screwed in place. The connecting-rods are then detached by removing the bolts which hold them in place. After this is done, the sleeves can be drawn out. This renders cleaning and inspection easy. The reassambling job is also very simple. The inner sleeve is first sprung into the working sleeve and the two are then put together into the casing. When the inner sleeve is placed in the sliding one, the ports are lined up so that they will be in the correct position when they are put back into the housing. It is impossible for the ports to get out of line when the sleeves are once in position owing to the fact that the bolts from the connecting-rods which drive the sleeves pass through slots in the different parts. The slots act as guides and hold the sleeves in the correct relative position to the casing.

An Angel on Ball Bearings

When the famous *Campanile di San Marco* in Venice collapsed about ten years ago it was decided to rebuild it "where it had stood and as it had stood," and this work of restoration has now been concluded, but while the tower stands to all appearances just as it was before, the construction methods which were employed in its reproduction were altogether modern and calculated to make it better able to resist storms, fire and earthquakes. Only a few parts of the old tower were used over again, but among these was the Marcus Angel, which for centuries had adorned the summit of the tower, and in replacing this image whose very large wings used to catch the full force of the wind, making the tower to sway and vibrate, it was decided to make use of ball-bearings for the purpose of obviating this evil. It was in fact a concern closely identified with the automobile industry in whose charge the design of this feature was left. The image is made of hammered copper sheets covered with gold leaf and weighs 1200 kilograms. In securing this considerable weight to the extreme top of the tower by means of an internal scaffolding, it was the object to permit the image to turn like a weathercock, so as to always present the smallest possible surface to the wind, and also to permit it to sway a few degrees in any direction independently of the tower and thereby cushioning the wind stress upon the latter. An end-thrust ball-bearing was secured in the scaffolding at the height of the angel's chest and from the upper one of its disks there was hung a long flexible rod passing down through the pedestal of the figure, with some side play, and supporting at its lower end, inside of the tower, a counterweight of 100 kilograms. Inside of the pedestal, which was bolted to the tower, there was secured a semi-spherical ball race containing a cage with sockets for 64 balls of 1⅜-inch diameter, and with an opening for passing the counterweight rod, and to the bottom of the scaffolding the other semi-spherical member of this bearing was securely fastened. In order to withstand the effects of dust and of the salty air of Venice without any attention whatever the bearings and balls are made of a special bronze in dimensions giving a large factor of safety, are packed in graphite paste, to serve as lubricant for perhaps a thousand years, and the whole mechanism is tightly encased to prevent all ingress of impurities, such as otherwise might be caused by the visits of birds, and also to prevent the wind from gradually blowing the lubricant away.—From *Werkstattstechnik*, June 15.

King 36 Roadster

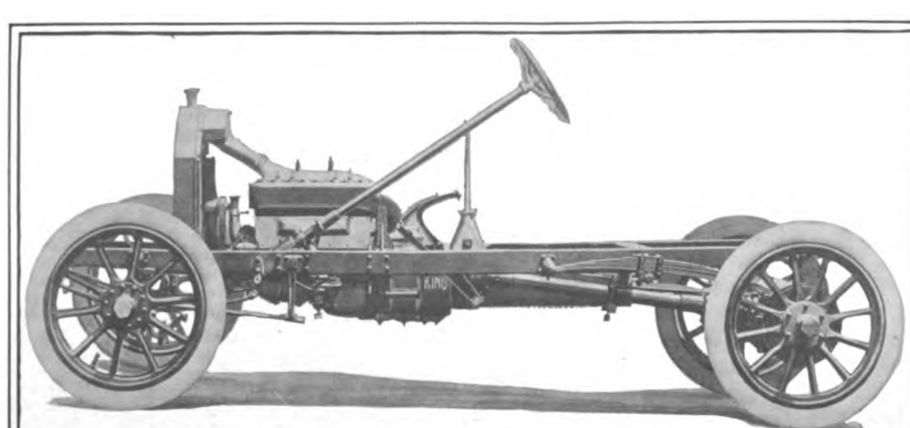
New Type of Body Features This Latest Addition to Company's Line

Rear Deck Compartment for Tires and Baggage—Long-Stroke Motor and King Patent Lubrication System

AMONG the cars which have recently made their initial appearance is the King 36-horsepower roadster, which, while possessing all the mechanical features characterizing the product of the King Motor Car Company, is of an entirely new body type, designed by Charles B. King.

The car, which has a 110-inch wheelbase, has very graceful and pleasing body lines. There is a rear deck compartment which incloses the extra tires and is intended to carry all necessary baggage as well. A glance at the illustration will show how this rear compartment idea has been carried out without causing the back of the machine to present a bulky appearance. The running-boards are free from tanks and boxes, a tendency which is fast becoming law to body designers. The doors latch from the inside, closing flush with the sides of the body. The cowl is on a very low slope and it is surmounted with a windshield which is a part of the standard equipment.

Another feature is the setting of the radiator and power plant 8 inches back of the center line of the front axle. This is done with the idea of giving better load distribution and of adding to the attractiveness of the car's lines.



Side view of 1913 King 36 roadster, showing radiator set back of front axle

The road clearance has been made 10 inches, but at the same time the body is hung low to lend a rakish effect to the whole.

The car in every way conforms to the King construction, the peculiar rear spring design being perhaps the most original and distinctive feature. The front springs are of the ordinary semi-elliptic type, but the rear ones, which are specially long and flat, are mounted in the reverse manner from that in which they are placed on the average car. They are supported at their centers on pivots which are fastened to the frame, and at their front ends they are also fixed to the frame. The rear ends operate in shackles which are mounted on the rear axle. With this construction it is claimed that the shocks received in passing over rough places, instead of being transferred to the occupants of the car, are taken up by the lever action of the springs and thrown back again. The action is very similar to that of the shock-absorber.

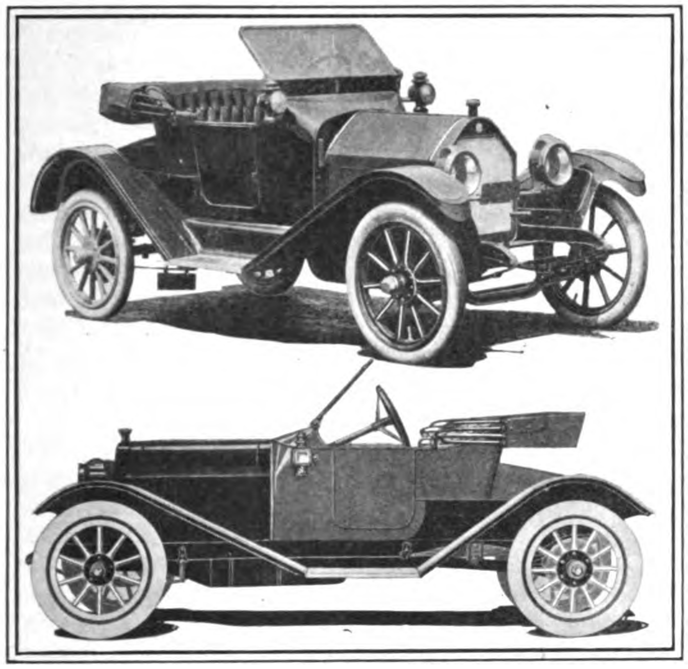
Details of the Long-Stroke Motor

In the new roadster, the long-stroke motor, which is of the four-cylinder, monoblock type, is to be found. The bore is 3 13-16 inches and the stroke is 5 1-8 inches, giving a stroke-bore ratio of 1.34. All the moving parts are inclosed. With the aim of getting the shortest possible line of travel for the gases, the valves are placed at an angle of 8 degrees. This also has a tendency to make the firing quicker, it is claimed. The intake and the exhaust open directly into the cylinders, there being no valve pockets. The crankshaft has two bearings and its diameter is 2 1-8 inches. This mounting of the crankshaft at the front and rear is a construction which is peculiar to the monoblock motor, and greatly economizes the power plant length. The timing gears are spirally cut and completely housed. A single cover plate houses all the valve-rods, tappets and springs. A peculiarly shaped fan, having two blades of aeroplane type is belt-driven. This, in connection with the thermo-syphon system of water circulation, makes up the cooling outfit of the car.

The carbureter is a Stromberg, being mounted on the valve side of the motor. The control is on the left hand side, so that the placing of the carbureter on the same side, together with the monoblock construction, makes for the minimum amount of manifold. The exhaust manifold is cast integral with the cylinders, the connection with the exhaust pipe being made at the rear of the cylinder casting.

The ignition is accomplished through the use of the Bosch magneto and dual system, using one set of spark-plugs. The magneto is mounted on a shelf at the forward end of the motor, and is driven by bevel gearing from the crankshaft, being placed at right angles to it.

Since the unit power plant idea is used, the flywheel, clutch and transmission being integrally housed with the crankshaft and motor, the lubrication of the entire mechanism is much simplified. In the King patented system oil which is put into the engine through the breather pipe serves for the motor, the



Three-quarter and side views of the 1913 King 36 roadster

clutch, the transmission and the universal joint at the front end of the propeller shaft. Each unit has its own oil compartment, and the inclosed flywheel serves the purpose of a pump in carrying the oil to an elevated trough, from whence it is delivered to the gears, bearings and so on. The grades down which the oil flows to the various friction points are made very steep, insuring positive lubrication of each bearing. The lower part of the flywheel housing is made the lowest part of the power plant, and the oil is led from the various lubricated points back into this part, which serves as a trough. In revolving, the flywheel rim runs through this trough and carries oil up into the elevated trough. Drain wells in each oil compartment catch dirt and residue and screens are provided which prevent this sediment from passing from one oil compartment into another. Both the engine base and the transmission case may be drained separately by the removal of pipe plugs.

As inspection of the chassis view will show, the control lever enters directly into the gearbox, which is made possible through the center control feature. By this construction, toggle joints and rocking shafts are done away with.

The clutch is of the multiple disk-type, consisting of thirty-two plates running in oil and contained in the flywheel. Transmission is selective, three speeds forward and reverse. The gears are flooded with oil at all times in the manner already explained.

A substantial torque tube incloses the propeller shaft which effectively maintains the relative positions of the rear axle and the transmission through the aid of two radius rods passing from the front end of the tube back to the rear axle at either side. This construction has long been a European-car characteristic and is also seen in several cars now made in this country of the monoblock-unit-power-plant type.

The torque tube bolts to the rear axle, which is of the floating type of Weston-Mott design. The weight of the car is supported on the rear axle housing, leaving the two halves of the axle shaft which pass from the differential to the rear wheels free to perform their driving function exclusively.

Novel Front Axle Mounting Scheme

The brakes are internal and external expanding, operating on the rear wheels through pedals. The right one of these pedals operates the emergency brakes and is provided with a catch for locking it in position when desired. The other pedal operates the clutch and the service brakes as well.

The front axle may be clearly seen from one of the illustrations. It is mounted at an inclination of 7 degrees, the idea in so placing it being to cause it to meet the road shocks more directly in line with the springs. The result is a caster effect. When the wheels are turned to an extreme left or right position they have an inclination towards the road. For example, if the wheels are turned to the left, they slant to the left, the claim being that tire wear is thereby reduced, and the strain on spindles, bearings and tires lessened.

The frame has a depth of 4 inches at its heaviest point in the center of the car, and it is constructed of pressed steel. It is strengthened by a cross brace at the point where the rear springs are pivoted, in addition to the motor and power plant hangings which also act as reinforcements.

The wheels are of the artillery type, of second growth hickory, and they carry 32 by 3 1-2-inch tires. The tread is the standard 56 inches.

The standard equipment of the new roadster, which, by the way, is to sell for $1,190, includes a mohair top and slip cover, windshield, magneto, acetylene gas tank, gas headlights, oil side and rear lamps, horn and tools. The trimmings on lamps and accessories are black and nickel.

The body design has already been brought out. The front fender unit construction, however, is worthy of mention. The usual type front lamp brackets are done away with, the lamps being mounted directly on a steel tie tube which passes from one fender to the other, with the idea of so effectively bracing the fenders and lamps that there is no vibration of either. The lamps are raised higher than in the usual construction for the purpose of eliminating long road shadows. Gas enters the lamps through these braces, which consequently perform a double function.

Motor Passenger Line for La Guaira

La Guaira, Venezuela, June 20—An extensive concession providing for an automobile passenger and freight service covering a considerable territory in this vicinity has been granted, subject to the approval of the national Congress. The concessionaire will construct the roads necessary to the maintenance of his schedule. The government will protect the enterprise from competition for a period of 30 years, but all tariffs must first be approved by the authorities before being made effective.

Standardization—Dollars and Cents

DOES standardization pay?

This question affects the automobile builder, the automobile engineer, the automobile salesmanager, the automobile advertising manager, the dealer, no matter in what city he be located, the garage man, irrespective of location, the repairman, the retail salesman and, lastly, the car owner. All are interested in the work of standardizing those car parts which close study and observation decide should be standardized.

Standardization has been defined in scores of different ways and there have been as many misinterpretations of it as there have been definitions: Standardization has to do with different automobile manufacturers making certain parts of their machines or parts of uniform size, as using standard sizes of bolts or nuts in many places. The use of accepted sizes of cotter pins; accepted sizes of lock washers; accepted threads on spark-plug sockets; accepted sizes of grease cups; accepted sizes and shapes of yoke ends; accepted wheel diameters for certain tire sizes; accepted sizes of base plates for magnetos; accepted sizes of flanges for securing carbureters to intake manifolds; accepted sizes of gasoline and water connections for the gasoline line to the carbureter and the water lines to the carbureter jackets; accepted sizes of pipe diameters for car parts; accepted lengths of control arms or magneto breaker boxes and carbureter throttles; accepted sizes of sockets for electric light bulbs; accepted tolerance in bearings, and a hundred other things.

Such accepted, or recommended, practices mean money to every person connected with the industry. To grasp this, paint two parallel pictures, one of the standardized car, the other the non-standardized product, and let the owner of each become a country-wide tourist. Every tourist meets with little troubles and delays and so will the man with the standardized car and also the one with the non-standardized machine. In each case a new spark-plug is needed. Mr. Standardized Owner can secure the required plug in any garage or repair shop; the plug may not be of the same make as the one it replaces, in fact it may never have been used on his particular make of car, but that is not a factor, as the plug socket is a standard size and will take a plug that can be purchased anywhere at any time.

Parallel with this Mr. Non-standardized Owner. The engineer of his car decided that all spark-plugs were faulty and had his company build their own plugs of a standard size that met his conceptions. A new plug is needed while touring through Mississippi. The local garage men do not carry the non-standard plug, although well stocked with standard articles. The tourists has no recourse but to telegraph to the nearest branch, or dealer in his car, and patiently wait for a shipment. It may be that the dealer is just out and in turn waiting for a factory shipment and so the delay is increased. Such are the misfortunes of non-standardized parts.

As a second parallel consider the car using a non-standard filler cap on the gasoline tank. This is a small detail, but if the thread and diameter are special to that particular car and a cover gets lost it means that a substitute can only be obtained from the factory, or a branch, or dealer. On the other hand, if the car uses a standard iron pipe size, covers for such can be purchased in every town or city in the country, or practically every blacksmith shop is equipped to manufacture such an article.

A third parallel may be found in the use of yoke ends for steering parts, of which the average repairman carries a small stock. Should one call for replacement in Kansas or Oklahoma, the car owner feels that when the standardized article is used it is a speedy repair, but if a non-standard size has been used the question becomes serious.

Should his car be equipped with standard flanges on the intake manifold it is possible to install a different carbureter in Dallas without losing more than an hour or so, if in the forenoon or afternoon, and without any loss of time if the change is made at night. Should the flange be a non-standard it is impossible to install another make of carbureter without having to get a new manifold and the transition extends itself into a week's task.

Should the car have a magneto with a standard base, a change can be made in any emergency and without any loss of time, whereas it is impossible if the car is not a standardized machine.

But there is another phase of standardization rather than that of convenience—it is one of economy in repair. A standardized car is cheaper to repair throughout the country. A repairman or garageman in Denver soon discovers that his help become expert in the repair of standardized parts as they meet them on different makes of machines; whereas when non-standard parts have to be repaired a difficult and special problem is presented. The workmen are not familiar with the case. More time is required. The repair is not so well done and the bill to the car owner is greater. Because of this it soon gets rumored around the country that certain makes of cars are expensive to repair, solely due to the lack of incorporating standard sized parts in it. Thus does the standard car become a vehicle of cheaper maintenance to its owner, a vehicle more readily repaired and a vehicle that soon gets an honest reputation for cheaper maintenance because of these factors. Thus it pays to standardize. It saves money to the owner; it adds skill to the repairman; it builds up reputations for the manufacturer; it frees the engineer of details and leaves him free to carry on research and progressive work, and it makes manufacturing quicker and cheaper to the concern building the standard parts which are sold to all of the different units constituting the industry.

Standardization is needed. It must not be too radical; it must not be the whim of the few but the mature judgment of the many; it must not precede practice but must follow it; it must not place any limitations on the inventive genius of the engineer; it must not hamper the development of the growing industry; and it must change as time demands, always shaping its course by the requirements of the period.

Metropolitan Speedway Planned

Associations to Build and Manage the Project Incorporated With a Capital of $1,500,000—International 500-Mile Race Proposed

FORMAL announcement of the plans for the construction of the Metropolitan Motor Speedway has been made at the offices of the company in New York. The Metropolitan Motor Speedway Association has been incorporated with an authorized capital of $1,500,000.

The association has been formed to take over 300 acres on the Jersey meadows near Newark for the purpose of constructing a motordrome and stadium. Ground will be broken this month and the Speedway is to be completed within a year. On July 4, 1913, the premier event will be staged—an international 500-mile race. Engineering offices have been opened in Newark, and a corps of experts engaged.

It is not merely intended to make the Speedway a stage for automobile speed contests. Long distance motorcycle races and other races will be held on the brick oval, while the infield will be available for aviation meets, baseball, football, field and track athletics, circuses, Wild West shows, etc. The entire plant will be inclosed by a high fence. The Speedway itself is to be 60 feet wide, excepting on the turns, which are to be 75 feet in width and scientifically banked with saucer curves.

Officers of the new company are as follows: H. E. Hoyt, president; A. R. Pardington, vice-president and general manager; Theodore F. Kerr, treasurer; W. H. Osborne, secretary; Fred J. Wagner, director.

Sales Managers' Meeting Put Off

Indefinite postponement has been taken as far as the convention of sales managers is concerned. The convention was originally planned for next week, but owing to the press of late business and preparation for the 1913 season it was found inadvisable to hold the convention until later.

According to announcement made by the Automobile Board of Trade the convention will probably be called for September. The regular monthly meeting of the A. B. of T. will be held July 11.

Motor Carnival Week Postponed

Automobile Carnival week, which was scheduled to be observed week after next, has been postponed until the week of September 9. Lack of interest in the project was the main reason for its postponement at this time. Another reason was the fact that July is normally vacation time on automobile row and as the 1912 business has been cleared up in good shape the row is quieter than it has been in several years. Only four agencies can deliver cars on the spot.

Denver-Chicago Reliability Run

Eleven Contesting Cars, Representing Commercial and Other Organizations of Colorado's Capital Reach the Windy City

CHICAGO, July 1—The Denver-Chicago reliability run reached Chicago to-day. The party comprised eleven cars, representing the commercial and real estate organizations of Denver, Col., the towns of Sterling, Longmont, Canon City, Steamboat Springs and Idaho Springs, in addition to four privately owned Denver machines. Governor J. F. Shafroth and Mayor Henry Arnold took part in the getaway ceremonies.

The tour started at 9 a. m. Tuesday, June 25, from the Denver Chamber of Commerce, and the participants were accompanied out of the city by a gala parade of machines. The party will remain in Chicago July 2, 3 and 4, and returning will leave here the morning of July 5, reaching Denver July 13.

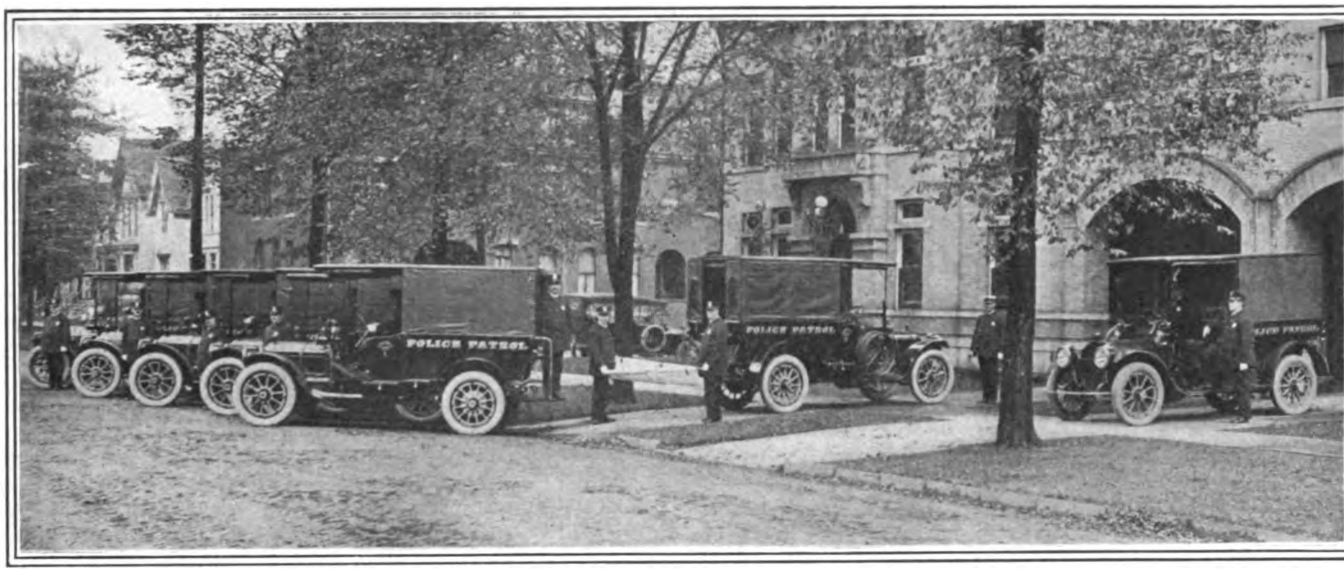
Each car was strung with banners and was well loaded with literature giving one hundred reasons why motorists should visit Colorado.

The cars entered in the run are Denver Real Estate Exchange car, R. R. Gillette; Chamber of Commerce car, Howard Smith; Denver Retail Association car, J. G. North; Sterling car, F. E. Frost; Longmont car, William McCreery; Canon City car, Mrs. Edith Myers; Steamboat Springs and Idaho Springs car, F. A. Craise; Denver privately owned and entered cars, C. L. Newcomb, John Brannan, W. H. Tompkins and Joe Lovan.

Twin Cities-Winnipeg Tour Plans

MINNEAPOLIS, MINN., July 1—With a message to the president of the state automobile association from Mayor R. D. Waugh, of Winnipeg, the Baby Mitchell Six Pathfinder has returned to the Twin Cities, with a scouting trip of 1,195 miles to its credit. The first leg of the return trip from Winnipeg ended at Grand Forks, N. D., 156 miles, passing through Emerson at the Canadian border, 68 miles from the start. The route was Hamilton, Glasston, St. Thomas, Auburn, Grafton, Harriot, Minot, Ardock, Lavant, Manville. At Grand Forks the arrival will be coincident with the opening of the North Dakota state fair. The next day's run was 163.8 miles to Breckenridge, Minn., through Crookston, Beltrami, Ada, Moorhead and Fargo, Comstock, Iverson, McCauleyville and Kent. A 20-minute control was established at Ada. The next leg was to Fergus Falls, Elbow Lake and Alexandria, Glenwood, Annandale, Rockford and Robbinsdale to Minneapolis. All sorts of scenic effects are to be found on the run, especially in the White Earth Indian reservation in Minnesota and in Canada. Returning the route is through lake park district, one of the most beautiful in the Northwest. Within the city limits of Minneapolis are 18 beautiful lakes such as cannot be found anywhere in similar location in the world.

News of the Week Condensed



A portion of Detroit's Packard motor patrol squadron. Officers in center represent first aid to injured

DETROIT Motorizes Police Department—With the addition of two Packard police patrols to the seven already in use, the motorization of the Detroit, Mich., police department is complete. Commissioner Croul declares that one automobile patrol with two men can cover as much ground as three horse-drawn wagons and give much better service. The cars in the department responded to 32,939 calls last year and covered 81,599 miles.

Berndt Assistant Manager for Remy—Arthur H. Berndt will become assistant manager of the Indianapolis branch of the Remy Electric Company September 1.

New Denver Accessory House—The Shaffer Auto Supply Company, 1240 Broadway, Denver, Col., is a new organization which will handle standard accessory and supply accounts.

Remy Appoints Lolly—The Remy Electric Company, Anderson, Ind., maker of the Remy magneto, has appointed W. H. Lolly of London, Eng., an engineer in the service department.

Loomis Resigns from Speedwell—Gilbert J. Loomis, who has been general sales manager of the Speedwell Motor Car Company for the past 5 years, has resigned, to take effect August 1.

Oustendorf Buys Out Partner—George Oustendorf, Franklin dealer in Buffalo, N. Y., has just bought out the interest of H. E. Crosby, formerly associated with him in the Franklin dealership.

Tisdale Buys Control—Glenn A. Tisdale, of the Franklin Motor Car Company, dealer for the Franklin car in the New York City territory, has bought the controlling interest in the firm of the John Kerkin Company.

Packers Branch in New York—The Packers Motor Truck Company, Wheeling, W. Va., has opened a branch office at 1734 Broadway, in the U. S. Rubber building, corner of Fifty-sixth street. Besides the office at that location, the Packers have a service station of 7,500 square feet, on West Forty-second street, with complete equipment and expert mechanics.

Dawson to Go on Stage—Joe Dawson, winner of the second annual 500-mile International Sweepstakes race at the Indianapolis Motor Speedway last Memorial Day, is to embark in the theatrical business. Dawson announces that he is being booked to appear in many of the larger cities during the next few months and will probably be engaged throughout the winter on the vaudeville stage.

To Control Taxicab Drivers—An amendment has been passed by the legislature of the Province of Quebec which will give the cities the right to make by-laws controlling chauffeurs of automobiles and taxicabs kept for hire as cabmen are now controlled, and to inspect the meters in taxicabs. It will also make it possible to establish a fine for passengers in these vehicles who do not pay the regular fare, the standard for which will be set.

Buy Out Broad-Oak Company—R. M. Weaver and W. J. Miller have purchased the entire capital stock of the Broad-Oak Automobile Company, which operates a sales agency and garage at 622 Oak street, Columbus, O. The purchasers take charge of the business July 1. Both men have had considerable experience in the automobile business and they announce improvements and extensions will be made. The concern has the central Ohio agency for the Chalmers and Pierce-Arrow.

R-C-H Branch for Frisco—To handle its constantly increasing business in the Pacific Coast territory, the R-C-H Corporation has completed arrangements for opening a branch and service station at San Francisco on July 1. The building secured for this purpose is a three-story structure on Ellis avenue, just off Van Ness, in the heart of the new automobile district of San Francisco. A floor space of 18,000 square feet is available for display and parts storage. The San Francisco branch will be used as a car and replacement distributing point for the entire West, and a sufficient supply of cars will be kept on hand to take care of rush orders at all times.

City's Street Cleaning Automobile—Mr. Edwards, street cleaning commissioner of New York City, intends to use motor trucks in the disposal of garbage.

Truck Saves $4,200 Annually—A milling company of New Orleans, La., has estimated that it saves $4,200 annually by the use of a 5-ton General Motors truck.

Wagner Sales Manager—Howard E. Wagner of New York City has accepted the position of sales manager with the Buffalo Electric Vehicle Company, Buffalo, N. Y.

Durable Dayton Service Station—The new service station and salesrooms at 1700 Wabash avenue have been opened for Chicago, Ill., users of Durable Dayton motor trucks.

Builds in Columbus—A permit for garage building has been taken out by Viola Horn, Columbus, O., who will erect a public establishment between High and Third streets.

Currier Now in Charge—M. B. Currier, Columbus, O., who has been a mechanical expert with the Interstate Auto Company, has been placed in charge of the Columbus agency.

Wilson Called East—Orin S. Wilson, for 2 years general manager of the Studebaker Colorado Vehicle Company in Denver, Col., has been called East to supervise more extensive territory. He has been succeeded by his assistant, J. C. Beck.

Lozier's New Boston Building—Work has been started on the foundation of the new Lozier building on Commonwealth avenue, Boston, Mass., and it is expected that the new structure will be completed and ready for occupancy about September 1.

Lansden Electric in Boston—The Lansden Electric Vehicle Company has been formed in Boston, Mass., with Albert B. Freeman, president; Gardner Freeman, treasurer, and William H. Britton, secretary. The company recently took the agency for the Lansden electric truck for Boston.

Automobile Affects Horse-Breeding—The great popularity of the automobile, according to army officers, is having the effect of causing a marked diminution in the breeding of middle and inferior grades of horses, thus rendering it difficult to secure animals for the cavalry and artillery service.

Locomobile Branch in New Quarters—The Los Angeles branch of the Locomobile Company, which was temporarily located at 942 South Grand avenue, is now occupying new permanent headquarters at Pico and Grand avenues. The new building was secured, as it is larger and offers more facilities for giving customers prompt and efficient service.

New Home for Motor Company—Negotiations are under way for a new home for the Longstreth Motor Car Company, Philadelphia, which handles the Alco. The plans provide for a modern concrete building approximately 66 by 125 feet at 2126-28-30 Market street. It is expected to have the building ready for occupancy about September 1.

Will Enrich Automobile Gasoline—The Acetol Company has been formed by P. C. Avery, of Milwaukee, Wis., and other interests to market an invention by Mr. Avery of a chemical compound to enrich gasoline. Mr. Avery is chief owner of the Avery Portable Lighting Company, which formerly produced the Auto-Gas tank and later the Electrobola motor lamps.

Denver Club Suggests Improvements—Mayor-elect Henry Arnold of Denver has asked the co-operation of the Denver Motor Club in the way of suggestions for the improvement of existing traffic ordinances and in the stationing of the traffic police squad. The club responded with suggestions for fifty-six ordinances, some of which are certain of adoption.

Keeton Company Secures Good Man—The Keeton Motor Company, Detroit, Mich., builder of the Keeton French type, has announced another addition to its office force in the person of H. D. W. MacKaye. He is now to be connected permanently with the Keeton Motor Company as assistant to the president, and will also take charge of the purchasing.

Government Department Buys Trucks—The Bureau of Engraving and Printing, like many other Federal departments, is gradually doing away with the horse-drawn vehicle in favor of the automobile. The purchasing agent of the department has just received bids for one 8,000-pound truck, one 5,000-pound truck, one coupé and one delivery wagon. The number of bids submitted was so great that announcement of the awards will not be made for several days.

Young Severs Lozier Connection—C. S. Young, engineer and designer with the Lozier Company, has severed his relations with that organization to become assistant general manager with the Regal Motor Car Company, Detroit, Mich.

Everett in Louisville—The Everett Motor Car Company, Detroit, Mich., has established a branch office in the Coleman building, Louisville, Ky. E. L. Jacoby, formerly manager of the Studebaker branch at Memphis, Tenn., is in charge.

District Managers Meet—Enthusiasm, good fellowship, business and pleasure were the predominating features which marked the 3 days' convention of the district managers, allied with the Willys-Overland Company, held at Toledo, O., recently. Each state in the Union was represented, as well as Canada. Among the pleasure features were the smoker at the Overland Club on Maumee Bay, banquet at the Toledo Yacht Club, launch rides on Lake Erie and a theatre party. The company intends to build 40,000 cars this year.

Outing of Overland district managers at Overland Club House, Maumee Bay, during annual convention

Kelly Branch in Indianapolis—The Kelly Truck Company has opened a factory sales branch and service station at 9 East Pratt street, Indianapolis, Ind. The company has a number of its trucks in operation in the city.

Richmond to Have Truck—Charles F. Taylor, of the Richmond, Va., tire commission, announces that the board is now considering the motorizing of the entire fire department. President Taylor says that if the fire department is motorized, the city will save at least 50 per cent. in operating expenses, making a total saving of $60,000 to $90,000 annually.

To Start Truck Line—An automobile truck service between Hamilton, Ont., and Toronto for the transportation of perishable and household goods between the two cities is being planned by the Grant Cartage and Forwarding Company which will place in operation ten machines as soon as the service is opened.

City Cars Need Not Register—Cars owned by the city of New Orleans, La., if plainly lettered, showing the department to which they belong, will not be required to carry license tags. This decision was rendered recently when an effort had been made to force the registration of the city's machines.

Shreveport Collects Car Tax—Taxes are being collected by the city of Shreveport, La., on approximately $1,000,000 worth of motor cars. The taxation, however, is not based on the valuation, but is graded as follows: 2 passenger cars, $2; 4 passenger cars, $3; 5 passenger cars, $4; 7 passenger cars, $5. Trucks pay $1 and public transfer wagon $10. The tax is assessed annually.

More Cars in Michigan—Secretary of State Martindale believes that the sale of automobile licenses this year will bring the State of Michigan $150,000. More than $119,000 already has been received. During 1911 the fees amounted to $102,913.

Scranton Repair Shop Burns Down—The repair shop of Robert Lance, Scranton, Pa., was burned recently.

Shay Leaves Ozburn Company—W. J. Shay has sold his interest in the Ozburn Automobile Supply Company, Memphis, Tenn., to N. F. Ozburn. Mr. Shay now will devote his time to the organization of the United States Sales Corporation, which will deal in accessories.

Big Convention of Haynes Men—About 300 salesmen and agents of the Haynes Automobile Company were entertained recently at the factory in Kokomo, Ind. The city was decorated for the occasion, every business house displaying Haynes pennants, while in many windows were shown parts of the Haynes car. The guests were forbidden to spend their own money, each man being given fifty certificates which were accepted as money by Kokomo merchants.

mers at the factory in Detroit. R. A. Dobyns, secretary of the Bay State A. A. for the past 2 years has taken Mr. Nichols' place with the Whitten-Gilmore Company.

Phelps Gets Promotion—George H. Phelps, who, during his year's service as manager of the retail branch of the Boston salesrooms of the Studebaker Corporation, placed it in second place in the number of sales, has been promoted to be manager of the New York branch of the company to succeed Charles F. Redden. Frank X. Coveney has been made manager of the Boston retail branch succeeding Mr. Phelps, while Phil Hawley is manager of the wholesale department in charge of the New England district.

Richards With Michigan—F. W. Richards, who was formerly connected with the Boston, Mass., branch of the Premier car, is now sales manager of the Boston agency recently opened for the Michigan.

Day Baker Lectures in Canada—President Day Baker of the Electric Vehicle Club of Boston, Mass., and agent for the General Vehicle Company, had the honor of being the first person chosen to deliver an address before the newly formed Montreal Electrical Society. His topic was the Electric Vehicle, Its Source and Its Future. He illustrated it with many lantern slides, among them ones showing the recent parade of electric vehicles in Boston.

Mercer Kansas City Branch—The Mercer Company, Trenton, N. J., has opened a branch in Kansas City, Mo., in charge of Roy O. Kendall.

Reorganizing Austin Company—With George H. Davidson and W. R. Shelby interested with James E. and Walter S. Austin, the Austin Automobile Company, Grand Rapids, Mich., is being reorganized with a capitalization of $500,000. Of this, $300,000 will be common stock and $200,000, six per cent. preferred. Stock will be open for popular subscription and a 50 per cent. bonus of common may go with the preferred. An advertising campaign will be inaugurated and it is planned to build a new factory.

Habersham Succeeds Villet—E. H. Habersham has been appointed manager of the wholesale branch of the Studebaker corporation in Washington, D. C., succeeding E. M. Villet, who has been transferred to the Fargo, N. D., branch.

Lowell Traffic Regulations—Street traffic rules have been adopted by the Lowell, Mass., city officials similar to the regulations in use in Boston and other cities designed to improve conditions. The new regulations provide that owners of vehicles must not allow them to stand for any great length of time unattended, and on some of the busier thoroughfares the vehicles must not stand only long enough for persons to enter or alight. All vehicles must at all times stand parallel to, and near the right hand curb. Vehicles are not allowed to stand within 75 feet of the corner of some of the intersecting streets on the main thoroughfares.

Halliday Traveling for Thomas—Norman N. Halliday, manager of the Boston branch of the E. R. Thomas Motor Car Company, has been despatched on a tour through the West by the factory to call on dealers and branch managers and also to establish agencies for the Thomas where needed.

Wants Better Regulations—Through its board of governors, the Bridgeport, Conn., Automobile Club is endeavoring to provide important changes in traffic regulations. Many complaints have been made that little attention is paid to the rules of the road in the city. The club officials want to have the rule of keeping to the right enforced, some of the busy streets made one way thoroughfares, and to prohibit vehicles standing on the streets for long periods where there is much traffic.

New Home of the George C. Brinkman Motor Company, which represents the Nyberg and National in St. Louis

News of the Garages

KOLB Builds in Erie—William Kolb has built a large garage on Spring street, Erie, Pa.

New Garage for Adams.—W. C. Garrison, Adams, Neb., has bought a lot, where he will erect a cement block building to be used as a garage.

To Give Out Contracts—The Ellis Motor Car Company, New York City, will soon give out contracts for the work of building a $12,000 garage.

Romare Enters Garage Business—O. E. Romare, formerly designer and maker of astronomical instruments, has decided to build a garage at Lake Geneva, Wis.

Municipal Garage in Columbus—Ordinances have been adopted by the city of Columbus, O., for an appropriation of $2,800 for the erection of a garage to house the motor patrol wagons of the police department.

Columbus to Have City Garage—The city government of Columbus, O., has voted for the erecton of a city garage which is to house the vehicles used by city officials. The city is now taking bids for the work.

Sturgeon Bay Garage Expands—The J. C. Dana Company, Sturgeon Bay, Wis., is building a 32 by 100 foot addition to its garage. A part of the addition will be equipped as a large repair shop. Elevators will be installed in the structure.

Toronto Will Get Another—A new garage will be added to Toronto's directory as soon as Death & Watson, Ltd., electrical engineers, complete the erection of their plans regarding an establishment for housing gasoline and electric cars.

Fireproof Garage Opened—A concrete garage has been opened in Rockford, Ill., by Lee Stewart. The garage is two stories high, but requires no elevator, as the lower floor is at the street level and the upper floor slightly above that of the alley.

Hayes Lays Out Plans—Edward Hayes, of Los Angeles, Cal., has laid out his plans for a one-story brick garage and repair shop. The building will be erected on a lot 55 by 75 feet, and will have a pressed-brick front, cement floors and composition roof.

Dorley Builds Addition—A large addition has been built to the garage owned by J. N. Dorley, Gloucester, Mass., giving a floor space of about twice the size of the old structure. A new office addition has been added to the front and a repair shop in the rear also.

Owatona to Have Garage—R. W. Sander and Paul J. Sander have leased a garage which is being erected at Owatona, Minn., and will have it equipped by July 20. The building is 50 by 114 feet and will accommodate fifty cars. P. J. Sander will have charge of the repair department.

Toledo Garage Issues Guide—The United Garage, Toledo, O., has issued an interesting guide showing several newly completed roads of northern Ohio and giving the best routes out of Toledo to distant points. A number of shorter routes and week-end journeys for pleasure jaunts are also given.

Janesville Establishment Enlarged—J. A. Strimple, Janesville, Wis., agent for Mitchell products, has purchased the garage and agency business of S. B. Echlin, 219 Milwaukee street, and will move there at once. He thereby becomes Reo and Chalmers agent, and plans to enlarge the building as well as his stock.

Bentley to Have New Building—B. Court Bentley, proprietor of the garage on Main street, Westerly, R. I., is to erect a new building on the site of the old structure which was partly destroyed by fire some time ago. The new building will be 30 by 100 feet with an addition in the rear 20 by 40 which will be used as a machine shop.

St. Paul Garage Changes Hands—Merrit J. Osborn, St. Paul distributor for White cars, has taken over the Western Automobile Company Garage and will operate it together with the establishment now conducted at 15 East Ninth street. At the second place the main office will be located and there trucks will be stored. A driver's school will also be conducted.

Ground Broken in Northampton—Ground has been broken on Maple street, Northampton, Mass., for a garage capable of housing thirty-five cars on the lower floor, and the walls will be built strong enough to carry an additional story whenever the business warrants the building being enlarged. It will have modern equipment and will be conducted by Frank S. Parsons.

Automobile Incorporations

Motor Fire Apparatus

ALBANY Installs Motor Apparatus—Albany was added to the list of cities having motor fire apparatus recently by the installation of a motor-driven fire engine.

Milwaukee Department to Be Modernized—Milwaukee, Wis., is in the market for three combination chemical and hose trucks which should not cost more than $6,000 each.

Cambridge in the Market—A committee of the Cambridge, Mass., board of aldermen has been appointed to consider the advisability of buying some motor fire apparatus for the city.

Motor Equipped Fire Apparatus—The Springfield, O., councilmen have decided to equip the present apparatus with motors instead of buying new ones. They will cost from $5,000 to $6,000 each.

Milwaukee's Cartercar Roadsters—The Chicago branch of the Cartercar Company recently received an order from the city of Milwaukee, Wis., for seven roadsters. The cars will be used in the fire department.

Arlington Wants More—The town fathers of Arlington, Mass., are so well pleased with the motor apparatus attached to the fire department that they are after more, and now they want a combination hose and engine that will pump a good stream.

La Crosse Safest City—The Wisconsin Fire Prevention Bureau, after inspection, has declared that LaCrosse has the least gasoline hazards in the state, in that both public and private garages have ideal facilities for storing and handling gasoline and oil.

Philadelphia Fire Department Motorizing—The city of Philadelphia will soon be in the possession of motor fire apparatus costing $35,000. This sum has been granted out of the recently floated city loan of $4,225,000. Seven automobiles are to be bought and bids will be taken on and after July 8.

A portion of the White contingent which took part in the motor vehicle trials of the Russian War Department

Washington Automobile Pump Satisfactory—Chief Wagner of Washington, D. C., has expressed his satisfaction with a new automobile fire engine which was tested here a few days ago. The engine and pump lifted more than 800 gallons a minute which is 100 gallons in excess of the required quantity.

Gotham's New Fire Apparatus—The International Motor Company has been awarded the New York City contract for five 2-ton chassis, mounted with combination hose and pumping bodies which are to be used for suburban service. These two pieces will make ten pieces of fire apparatus delivered by the company to the city of New York.

Watertown Orders Motor Fire-Wagon—The Selectmen of Watertown, Mass., have placed an order with the Locomobile Company, Bridgeport, Pa., for a new motor combination chemical that will cost $5,800 and which is to be delivered August 1. It will be housed in the new fire station recently built on Mt. Auburn street in anticipation of such a purchase.

Eight Columbus Fire Automobiles—The Seagrave Company, Columbus, O., has been given an order by the city of Columbus, for six automobile tractors, four combination horse and chemical wagons and one supply truck, to be delivered and paid for by $49,850. The Columbus Buggy Company has been awarded a contract for a squad wagon which is to cost $2,050.

White Leads in Russian Army Test—The White Company, Cleveland, O., has received news that the White team in the Russian War Office motor vehicle trials still had a perfect score after covering 1540 miles of the difficult test route. At the time the report was sent only 420 miles remained to be covered. The White cars also surpassed the European cars in the trial in economy of gasoline and oil.

Motor Fire Apparatus for Taunton—A Pope-Hartford combination motor chemical and hose truck that was built from designs submitted by Chief Leonard of the Taunton, Mass., fire department, has been delivered. This is the first step toward motorizing the Taunton fire department. The new vehicle combines some new features not embodied in regular motor trucks. The hose body is built in two box-shaped compartments which have a capacity for 500 feet of hydrant hose each, while these boxes are so arranged that they afford seats for the firemen, and the ladders being carried on the sides make a back rest for the men. This vehicle will take the place of two hose wagons and one chemical which means the passing of six horses. So well pleased are the builders of the truck that they have decided to build others along these same lines.

Automobile Incorporations

Columbus, O.—Federal Auto Accessories Company; capital, $2,000; to deal in all kinds of automobile accessories and supplies. Incorporators: J. R. Loofburrow, H. M. McDonald, W. C. Wetherhold, N. J. Mace, M. L. Mace.

Louisville, Ky.—Punctureless Tire Company; capital, $5,000; to manufacture a punctureless tire. Incorporators: Andrew T. Murphy, John H. O'Neill, John S. Hobson.

Muncie, Ind.—Feeney-Hurd Company; capital, $20,000; to manufacture automobile accessories and supplies. Incorporators: Edmund J. Feeney, James H. Leffler, Carl E. Hurd, J. D. Miltenberger.

Los Angeles, Cal.—Essenkay Sales Company; to sell a resilient filler for automobile tires. Incorporator: L. N. Brunswig.

Lynn, Mass.—Seymour Avenue Garage; capital, $25,000; to engage in the garage business. Incorporators: Charles R. Sibley, John E. Moulton, Ellery Jefts.

New York City.—American Motor Freight Company; capital, $25,000; to conduct a freight transfer business. Incorporators: Harry G. Waring, Harvey W. Bell, Howard G. Philipps.

New York City—Amherst Auto Renting Company; capital, –5,000; to rent automobiles. Incorporators: Peter V. Hoyt, Daniel J. McAndrews, George Schippereit.

New York City—Universal Auto Supply Company; capital, $10,000; to manufacture automobile supplies and accessories. Incorporators: John J. Tracy, George F. Connelly, John R. Hunt.

New York City—Goldfinger Auto Renting Company; capital, $2,000; to conduct an automobile-renting business. Incorporators: Benedict Goldfinger, Walter E. Fisher, Isaac Wolf.

New York City—Long Acre Garage. Incorporated; capital, $1,500; to conduct a garage business. Incorporators: Lewis M. Borden, George Gulbransen, Joseph F. Taylor.

Scituate, Mass.—Egyt Garage & Machine Company; capital, $6,500; to conduct a garage and repair business. Incorporators: William E. Chaffin, Charles M. Litchfield, Charles W. Pears.

Syracuse, N. Y.—Mohawk Tire Company; capital, $6,000; to engage in the manufacture of automobile tires. Incorporators: Henry J. Moses, Winifred G. Rice, Clarence E. Rice.

Toledo, O.—Peerless Rubber & Tire Company; capital, $10,000; to manufacture tires and other accessories. Incorporators: R. G. Wierman, Jno. T. Hickman, Edward Umbstraedter, J. R. Humphrey, William B. Woods.

Toledo, O.—Walker Tire Chain Company; capital, $15,000; to manufacture tire chains and deal in accessories of all kinds. Incorporators: Henry R. Rohrman, Charles A. Newman, Charles P. Eger, A. M. Edwards, George C. Bryce.

CHANGES OF CAPITAL

Detroit, Mich.—Keeton Motor Company; capital increased from $10,000 to $300,000.

Lexington, Ky.—Bayless Motor Car Company, name changed to Central Motor Car Company.

Toledo, O.—Rassel Motor Car Company; capital decreased from $125,000 to $95,000.

Factory Miscellany

BIG Pennsylvania Tire Plant—The new factory of the Pennsylvania Rubber Company, Jeanette, Pa., consists of shops, stockrooms, storerooms and other departments aggregating a floor-space of 117,000 square feet. The main building is 300 by 50 feet and three stories high, in addition to which it has a basement 150 by 48 feet. The mechanical goods department is a single-story building, 216 by 230 feet, with a basement 116 by 90 feet, and an annex, 43 by 24 feet. Among the products of the factory are Vacuum Cup tires and other soft and hard rubber goods.

Florida Factory Crystallizing—C. W. Birchwood, Chicago, Ill., plans to establish an automobile factory at Jacksonville, Fla.

Buffalo Pump Maker Builds—The Manzel Brothers Company, Buffalo, N. Y., is building addition to its factory. The company makes automobile pumps.

New Tire Factory Building—Indianapolis, Ind., will soon have another large factory building, this being the new $100,000 plant which will be built by the G. & J. Tire Company.

Dayton Body Factory Building—The Dayton Body Company, Dayton, O., has acquired a site upon which it will erect a new factory building in which to carry on its manufacturing operations.

Carbureter Company to Expand—The Star Carbureter Company, 685 East Atwater street, Detroit, Mich., is considering the erection of a factory annex to increase its output of carbureters and other automobile parts.

Bizzants Is Chief Engineer—Fred Bizzants has taken the position of chief engineer and factory manager for the Gramm & Bernstein Company, Lima, O., which will soon open a factory for the manufacture of motor trucks. The plant of the American Strawboard Company is being remodeled into a factory for the making of motor trucks.

Locomobile's Truck Plant—The Locomobile Company, Bridgeport, Conn., has commenced work on the new building which is to be used for the construction of its commercial vehicles. The new building should be completed within the next 60 days and until that time trucks will be constructed in the regular departments of the factory.

Students Visit Goodyear Plant—Accompanied by Dr. F. H. Thorp, one of the professors in charge of the chemical engineering course at the Massachusetts Institute of Technology, seventeen or eighteen M. I. T. students visited the plant of the Goodyear Tire and Rubber Company, Akron, O., recently.

Another Plant for Canadian Company—D. Lorne McGibbon, president of the Canadian Consolidated Rubber Company, has announced that the company has decided to enlarge the scope of its business by erecting an additional factory for the exclusive manufacture of automobile tires, the demand for which has become very great in Canada. The president stated that the present plant turned out a certain quantity of tires, but business was so rapidly increasing that a daily output of five hundred tires was necessary and will be provided for when the projected factory is completed. The production will be increased from time to time. Mr. McGibbon said that the new plant would involve an expenditure of a million dollars, as it is the wish of the directors that it be the most up-to-date factory of the kind in the world. The exact location, Mr. McGibbon stated, had not yet been decided upon, but the company will decide this matter in the near future.

Showing the immense new plant of the Pennsylvania Rubber Company at Jeanette, Pa.,

Another Factory for Sandusky—General contractor Alfred Schnurr, Sandusky, O., will erect a plant for the Suspension Roller Company in the near future.

Adding to Plant Facilities—The Hayes-Ionia Company, Ionia, Mich., has closed a contract with Theophil F. Banhagel for the construction of four kilns and a machine room addition to its factory.

New Searchlight Plant—The Searchlight Company has bought property at 2416 Fourth street, S. E., Minneapolis, Minn., for a branch factory. It will erect a one-story building of brick and concrete to cost $3,000.

Baker Builds Canadian Factory—The Baker Motor Vehicle Company, Cleveland, O., has incorporated in Canada under the name of Baker Motor Vehicle Company, Ltd., of Canada, A factory will soon be erected in Toronto, Ont.

Truck Plant in Toledo Building—Operations have been started in Toledo, O., to erect a three-story factory building, 75 by 125 feet, for the Shop of Siebert, originally wagon and carriage builders, but now manufacturers of a motor truck.

Iowa Ford Assembling Plant—Work began this week on a $70,000 five-story brick building to be used as the home of the C. L. Hering Motor Company, Des Moines, Ia. On the completion of the building all Ford cars sold in Iowa will be assembled here.

New Michigan Truck—The Wenonah Motor Car Company, Bay City, Mich., has entered the field with a light truck. The designing and manufacturing have been in charge of G. Earl Porter, formerly with the Detroit Motor Wagon. Bay City business men are backing the project.

Ford Plant for Frisco—A $300.000 automobile assembling plant for San Francisco in the immediate future was the interesting announcement from the Ford Motor Company at Detroit recently. The plant will be capable of handling 5000 cars during a season and will employ 300 skilled workmen.

Ford Buys in Canada—The Ford Motor Company has bought a large tract of river front property in Walkerville, Ont., adjoining the site of the firm's present Canadian plant, and announces its intention of erecting a large addition to its factory. When completed, the Ford plant will give work to 2,000 men.

To Enlarge Kentucky Plant—H. B. Hewitt, of the electric vehicle department of the Kentucky Wagon Works, Louisville, has established an agency in Chicago. He says the electric vehicle department of the Kentucky plant will gradually be enlarged until it becomes probably the most important branch of the business.

Kenton Adds Repair Department—The Kenton Gas Engine Company, of Kenton, O., has added an automobile repair department to its plant. The company will also handle a full line of motor car accessories as well as the Kenton agency for the Knight tires. T. A. Taylor is general manager of the concern.

Avoiding Canadian Duty—American automobile manufacturers get by the heavy duty on motor cars in Canada by shipping the parts across the border and assembling the car on Canadian soil. The Canadian duty on American-made automobiles completely assembled is about 35 per cent., while the duty on parts imported is about one-half that sum.

To Enter Automobile Business—The firm of John Immel & Sons, Columbus, O., has taken the first step towards entering the automobile business. The concern has completed the erection of a large plant where all kinds of automobile repairing is now being done in addition to body painting. J. E. Jolly, formerly connected with the Packard factory, is foreman of the department.

Lima May Have Tire Plant—E. Jefferson, Pittsburgh, Pa., visited Lima, O., recently with a proposition to establish a $500,000 tire manufacturing plant in that city in case the local people offer the proper inducement. It is announced that the promoters will furnish 52 per cent. of the proposed capital of $500,000 if Lima people subscribe the remainder. It is proposed to give employment to 275 men.

To Make Automobile Axles—A company capitalized at $175,000 has been organized at Kalamazoo, Mich., to manufacture automobile axles. A site for a plant has been purchased and work will be begun soon. O. K. Burkhart and M. H. Lane of Kalamazoo, and Fred Lee of Dowagiac are interested. M. H. Clary of Buchanan, manager of an automobile axle plant there, will take charge of the Kalamazoo plant. The factory at Buchanan will continue to manufacture buggy axles, and this part of the business will be enlarged. The auto axle manufacturing department probably will be brought here.

floor space of 117,000 square feet. Over 900 persons are employed, some of whom are here shown

Can-Holding Bracket; Electric Tail-Light; Baby Klaxon Coming Out; Unique Motion Writer; Electric Hand Drill; Priming Cup and Spark-Plug; Dashboard Switch for Electric Lighting Systems

Oilzum Can Holder Brackets

ECONOMIC arrangement of baggage on a touring car is a problem which puzzles many automobilists. As a consequence, running-boards are frequently packed in a most uncomfortable manner. To reduce this nuisance as far as possible the White & Bagley Company, 100 Foster street, Worcester, Mass., have designed oil-can brackets, Fig. 1, which have the purpose of holding the oil-cans to the running-board at a suitable point of the same. Each bracket is a bronze T, the leg of which is bent to fit under the running-board. The bent portion has two holes, through which screws are passed for fastening the bracket to the board. The upper portion of the leg has a bored extension through which is laid a strap which serves to secure the oil-can to the running-board.

Edelmann Electric Reer-Lite

E. Edelmann & Company, Chicago, Ill., are the manufacturers of an electric lamp which serves to illuminate the rear number plate, while some of its light passes through a red jewel. The lamp is stationed in a box to which a frame is attached, which is capable of holding a license plate of any size. The whole arrangement is secured to the number plate bracket.

New Smaller Klaxon Signal

A new horn, unchristened as yet, is being brought out by the Lovell-McConnell Manufacturing Company, Newark, N. J., maker of Klaxon and Klaxonet signals. The new horn, Fig. 2, closely resembles the Klaxonet in shape and is constructed on the same general principles, the sound being produced by the ratchet teeth rotated by the motor throwing the stirrup on the diaphragm into vibration. In this way the small horn produces the well-known Klaxon signal.

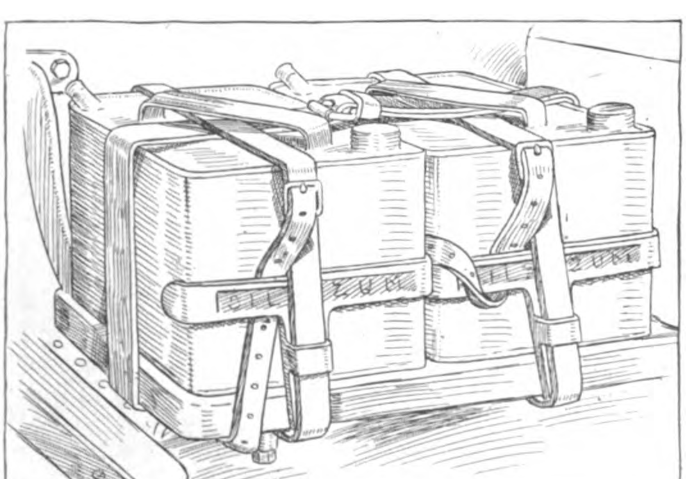

Fig. 1—Oilzum brackets in place on a running-board with cans strapped thereto

Unique Detective Recorder

The instrument shown in Figs. 5 and 6 is the Unique Recorder, made by the Unique Recorder Company, Hazleton, Pa. Its purpose is to prepare a record for the owner's information, giving the length of time during which a car has been operated each day of the week. At the same time the Unique Detective acts as an 8-day clock which is attached permanently to the

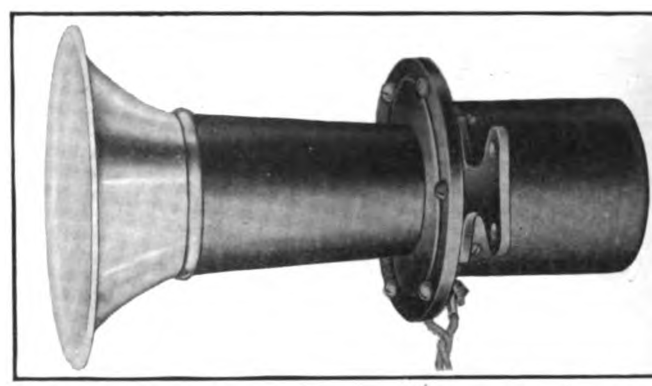

Fig. 2—New unnamed type of Klaxon horn which will be out in September

dash. The appearance of the device is seen in Fig. 5, where it is shown attached to a brass plate in place of the dash. The clock is wound by means of the key at the bottom and set by a stem which is not visible in the illustration. The entire clock mechanism is enclosed in a dust and waterproof casing which is hinged onto the hind casing containing the recorder mechanism, shown in Fig. 6. As this illustration shows, the recorder apparatus is very simple and foolproof. It consists of a pencil Pl steadily raised by the action of the clockwork, which at the same time rotates the recorder sheet which is marked with twice 12 hours once in 24 hours, the point of the pencil bearing against the surface of the sheet. The gear G makes one revolution a day. It is in mesh with the gear Gl, the shaft of which carries another gear meshing with the rack R, so that the rotation of the gear Gl lifts the rack which carries the pencil Pl. The gear Gl rotates on a fork, the end F of which is pivoted on an extension of the stationary post which guides the rack R, while the end Fl is drawn upward by the spring S, which thereby holds it in engagement with the Gear G. To prevent the gear Gl being turned back by the weight of the rack, the pawl P is provided. After one week, when the pencil has traveled from its lowest to its highest position, the owner opens the recorder casing by means of a cam key seen on the right-hand side of the device and disengages the pawl, so that the rack returns to its lowest position. Needless to say, the resultant between the rotary movement of the sheet and the radial one of the pencil is a spiral as shown in Fig. 4. Now the process by means of which periods of rest and motion are distinguished on the recording sheet is as follows: The pendulum P moves whenever the car is in motion, and its movement results in a series of oscillations on the record which appear in the form of heavy lines. The manner in which these oscillations coincide with the spiral-bow sections indicates the time at which the car was running.

Buckeye Electric Breast Drill

The American Foundry Company, Leipsic, O., manufactures the Buckeye electric breast drill. This portable tool is made in a convenient size and shape and may be operated by means of either direct or alternating current. On the drill is mounted a switch which may be moved to neutral or to either side to make the drill rotate in either direction or keep it at rest. The drill spindle sleeve is fitted with a breakover movement which permits of bringing the spindle into a locking position in which it is held from turning by jaws fixed to the drill frame.

Champion Starter Spark-Plug

A combined priming cup and spark-plug has been brought out by the Champion Spark-Plug Company, Toledo, O. This plug has part of its shell bored in an annular chamber open at the bottom of the plug. Into this chamber opens a priming tube which is attached to the side of the shell and consists of a priming hole, a passageway leading therefrom to the annular

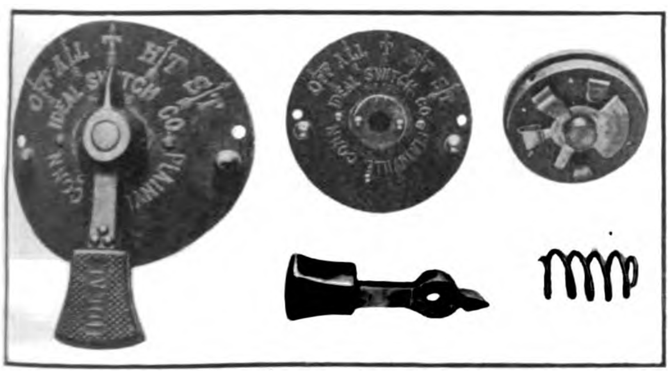

Fig. 3—Ideal lighting dashboard switch and component parts of same

bore of the shell and a needle valve which may be closed so as to shut off the interior of the annular bore against the outside. Gasoline may be introduced by unseating the needle and squirting in the fuel by means of an oil-can, after which the needle is tightened again on its seat.

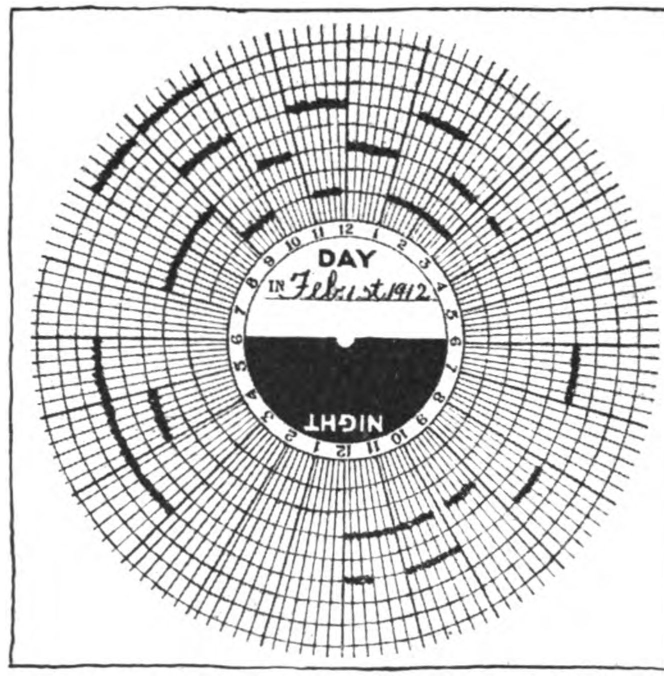

Fig. 4—Record chart for one week, made by the Unique Detective Recorder

Ideal Lighting Dash Switch

One of the latest types of switches is shown in Fig. 3, this being the product of the Ideal Switch Company, Inc., Plainville, Conn. The model shown here is attached to the dashboard, which is bored with four holes for the wires leading from dynamo or battery to the head, side and tail lights and back to the source of current, according to whether it is desired to shut off the light, use any one set, two or three sets of lamps. Seven possible positions of the contact maker have been provided and are marked on the dial or face of the switch. The outside of the switch casing is etched, as shown in Fig. 3, and the hard-rubber handle is designed in a pleasing shape. The view of the inside of the switch shows its simple construction. The leads from the current course to the three sets of lights are connected to the three bent contact pieces, while the return wire is connected to the rotary contact piece.

The spring illustrated serves to space the rotary contact piece from the switch base carrying the other three contact pieces.

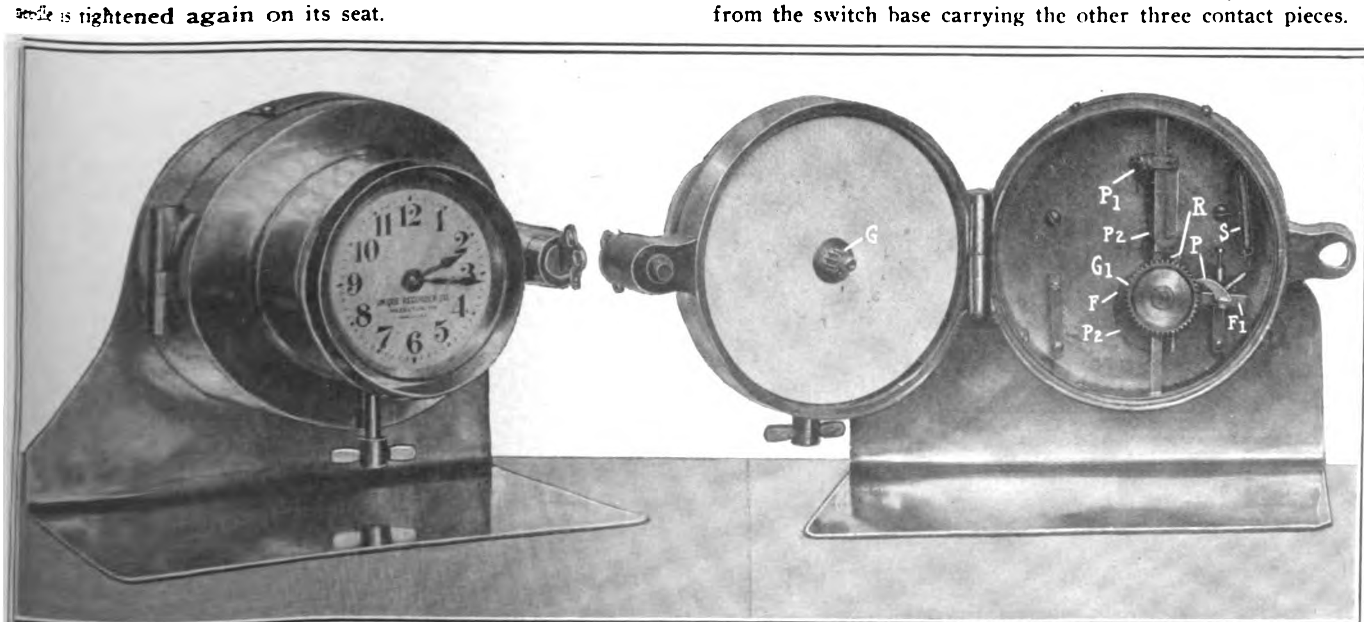

Fig. 5—Front view of Unique recorder. Fig. 6—Mechanism of the Unique motion recorder, comprising gears and rack actuating chart and pencil, and spring insuring engagement

NUMBER Plate Arrangement—In which number plate and tail light are arranged at the two sides of the rear end of the car.

This patent refers to the use of guards at the sides of the automobile body, Fig. 1. These guards gave rearward extensions E and E_1, and a license plate L is mounted on the extension E, while a lamp L_1 is on the extension E_1. The plane of the number plate is mounted at a slight angle to the transverse axis of the vehicle, so that the numbers appearing on the plate may be plainly read from behind the car, while the light radiated by the tail lamp L_1 strikes the face of the plate and illuminates it. The tail lamp may be fitted with a lens which concentrates part of its light rays upon the number plate.

No. 1,029,063—to Russell Huff, assignor to Packard Motor Car Company, Detroit, Mich. Granted June 11, 1912; filed October 28, 1910.

Valveless Motor—In which a bored piston and a rotary valve serve to regulate the flow of fresh and dead gases.

Fig. 2 illustrates the four-cycle motor described in this patent, consisting of a cylinder C which is provided with orifices O and O_1. These orifices are capable of communicating with the exterior, either for the purpose of admitting fresh gases into the combustion chamber or of scavenging burned gases. In the cylinder reciprocates a rotary piston P which has channels for establishing communication between the interior of the cylinder and the orifices mentioned. A rotary distributer R is provided, which is adapted to admit gas into the cylinder through one of the piston channels and one of the orifices. A prolongation P_1 of the piston has a groove G, in which rides a finger E, controlled by the rotary distributer so as to rotate the piston. The relation between piston and distributer is such that the piston, during compression and explosion strokes, covers the orifice leading to the distributer, while at the same time the latter interrupts the current of mixture from the carbureter to the cylinder, all communication between these two parts being cut off during the two strokes named.

No. 1,029,192—to Charles Edouard Henriod, assignor to Société Ribeyrolles & Cie., Puteaux, Seine, France. Granted June 11, 1912; filed November 23, 1909.

Axle-Drive Mechanism—Being of the worm-and-gear type with a thrust-taking member interposed between worm and axle proper.

This construction, Fig. 3, has a stationary axle A on which wheels are journaled and which is connected by a double chain drive to a differential shaft D. A worm gear is provided on the differential shaft, being engaged by a worm W which is carried on the motor shaft S, the latter being in thrust line with the axle. A thrust member T is interposed between the shaft S and the front side of the axle so that all thrust is absorbed between axle and shaft D.

No. 1,029,736—to James H. App, Detroit, Mich. Granted June 18, 1912; filed July 5, 1911.

Method of Cooling Motor—Which consists in casting the inactive face of the engine pistons with radiating studs for air cooling.

This patent refers to a two-cycle engine construction which includes a cylinder, cylinder head and crankcase. A hollow piston is closed at its upper end; it has a smooth working face, while the inactive face of the closed end is cast with heat-radiating studs. Diametrically disposed within the piston is a wristpin which is engaged by the pounded head of a connecting-rod. A deflector plate extends from a portion of the wall of the piston close to the connecting-rod head, and the deflector and head co-operate in deflecting the gases toward one side portion of the piston where an outlet is provided for the gases traveling to the combustion chamber.

No. 1,028,359—to Chester Charles Jones, Beatrice, Neb. Granted June 4, 1912; filed March 5, 1909.

Tire—In which two coiled springs, one arranged within the coils of the other, take the place of inflated inner tubes in the casing.

This patent refers to a tire construction comprising two coiled springs, one of which is situated within the other. On the outer spring a shoe is arranged. This spring carries pins which engage the shoe thereby holding spring and shoe in fixed relation.

No. 1,030,263—to Stephen A. Matarazzo, Wilmerding, Pa. Granted June 18, 1912; filed September 18, 1911.

VOL. XXVII NEW YORK—THURSDAY, JULY 11, 1912—CHICAGO NO. 2

THE AUTOMOBILE

Records Go at Old Orchard Beach

Disbrow, in Case, Lowers Mile Figures to 35.1 Seconds, Clipping 3.9 Seconds from Former Mark—Simplex Covers 5 Miles in 4:04.50 and 10 Miles in 8:53—Lewis, Stutz, Captures 100-Mile Event in 1:32:43.60

General view of the old Orchard Beach course, looking south, during the 100-mile race on the second day

OLD ORCHARD BEACH, ME., July 6—Once more Old Orchard has had an automobile meet, and once more the famous beach has made good as a race course. On July 4, 5 and 6 some of the best drivers of the country appeared here and many new marks were set up for the course.

Louis Disbrow in his famous Jay-Eye-See, Harry Grant, Joe Nikrent, Jack Rutherford, Jack Le Cain, Joe Matson and other noted drivers were all on hand to do their little stunt to show the Maine devotees of automobiling just what real racing is. And everyone of them made good, to a greater or lesser degree.

While at the races last September there were some marks set up for the Old Orchard Beach course that were questioned, most of those were beaten at the meet just concluded today. Louis Disbrow set out to establish a beach record in his Jay-Eye-See. He did it. On Thursday, July 4, he took a long flying start and covered the mile in 35.1 seconds. Last year L. F. Baldwin in his big Stanley steamer did the distance in 39 second's flat.

Today, the last of the meet, Disbrow in the Simplex Zip covered 5 miles in exhibition in 4:04.50 and did the 10 miles in 8:53. These are not as good as the marks given for last fall's races, but as the course in 1911 was questioned, it is thought the new figures set by Disbrow will be taken as the standard for the beach.

On Friday "Bill" Endicott in his Schacht did the 100 miles in 1:36:41, which bettered the time of 1:39:50 made the year before. But even this mark did not stand long, for today Dave Lewis in a Stutz covered the distance in 1:32:43.60.

Line-up of contesting cars for the 100-mile race on July 4, won by Stutz, No. 4

Perhaps the most thrilling event of the 3 days was the 100-mile race on Friday. Jack Rutherford, winner of the century the year before, was out to repeat the performance. On Thursday he burned out a clutch, but his machine was in fine fettle for this event on Friday, or at least seemed to be.

For 99 miles he held the lead as the cars raced around the course and as some were left by the wayside. As he entered his one-hundredth mile the oil supply failed and Bill Endicott, who had been running second, passed the National and won out. It developed that the oil tank had begun to work loose in the fortieth mile. Rutherford kept on, however, occasionally easing up his machine. The continual jar had its effect and at last the oil gave out altogether. He burned out a bearing at the finish, but still was able to cross the line 9 seconds behind Endicott.

On the glorious Fourth there were fully 50,000 people at the beach to see the sport. The next 2 days, however, for all they developed better sport, proved to be disappointing from the attendance point of view.

The officials were: Referee, Daniel W. Hoegg, Jr.; Starter, John C. Herrison; Assistant Starter, W. A. Creighton; Judges, Wesley G. Smith, William Whittier, W. J. Milliken; Representative of the A. A. A., Daniel W. Hoegg, Jr.; Timer, George E. Barbour, Jr.; Assistant Timers, J. C. Estes, W. F. Coffey, W. H. Swett, George H. Sears; Scorer, L. M. Hart.

The following is a summary of the 3 days:

FIRST DAY

One-mile time trials, flying start

No.	Car	Driver	Time
	Jay-Eye-See	Louis Disbrow	35:10
3	National	John Rutherford	47:00
7	National	Neil Whalen	47:50
21	Chadwick	L. C. Hersey	55:10
1	Berkshire	Harry Grant	58:00

Class C, non-stock; 161 to 230 cubic inches; 5 miles

14	E-M-F	Billy Burke	No time taken

Class C, non-stock; 231 to 300 cubic inches; 10 miles

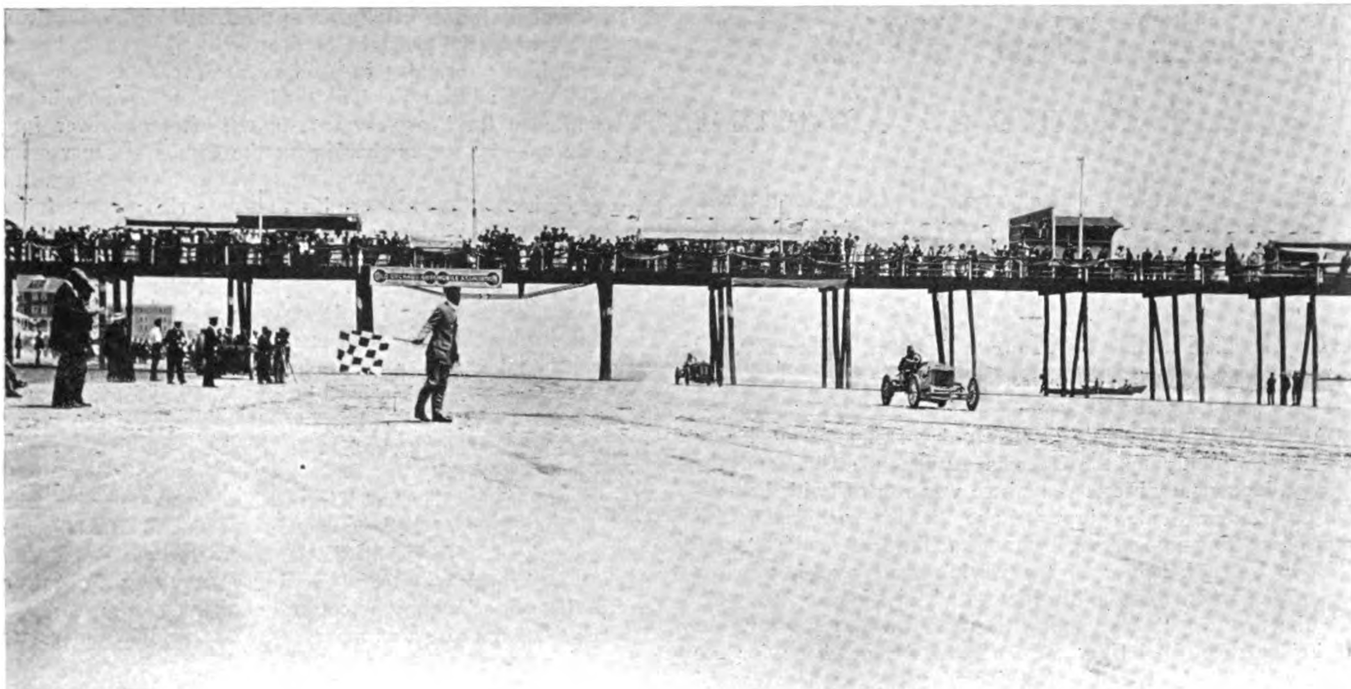
5	Case	Joe Nikrent	10:28.75
11	Mercer	John De Palma	10:30.75
9	Lexington	James Esleeck	No time taken
10	Case	Louis Disbrow	Did not finish

Class C, non-stock; 301 to 450 cubic inches; 5 miles

3	National	John Rutherford	4:25.80
4	Stutz	Dave Lewis	4:42.10
6	Schacht	Bill Endicott	4:45.00
7	National	Neil Whalen	4:46.50
1	Berkshire	Harry Grant	No time taken

Start of 231-300 cubic inch race on July 4

Hummel's Mercer skidding at outer mark in 50-mile race



Case Bullet leading Hummel's Mercer in the 50-mile race on July 5. The Mercer won the race

Class E, non-stock, under 600 cubic inches; 10 miles

2	Simplex Zip	Louis Disbrow	8:36.75
12	Fiat	Joe Matson	8:50.10
4	Stutz	Dave Lewis	9:00.00
18	Bianchi	Charles Basle	10:10.14
7	National	Neil Whalen	Withdrawn
3	National	John Rutherford	Withdrawn

Class E, non-stock, special event (three races running simultaneously); 100 miles. Race A, 301 to 450 cubic inches; Race B, 451 to 600 cubic inches; Race C, over 600 cubic inches. Race stopped at end of 75th mile

4	Stutz	Jack LeCain (75 miles)	1:17.48.75
1	Berkshire	Harry Grant (75 miles)	1:21.06.00
7	National	Neil Whalen (65 miles)	1:21.12.00
3	National	John Rutherford	Did not finish
6	Schacht	Bill Endicott	Did not finish
12	Fiat	Joe Matson	Did not finish
16	Fiat	Robert Stuart	Did not finish
18	Bianchi	Charles Basle	Did not finish
21	Chadwick	L. C. Hersey	Did not finish

SECOND DAY

Class E, handicap, non-stock, under 301 cubic inches; 10 miles

14	E-M-F.	Billy Burke (22 sec.)	5:49.50
11	Mercer	John De Palma (scratch)	5:57.10
17	S. P. O	Howard Plimpton (36 sec.)	6:16.50

Class D, non-stock, free-for-all; 5 miles

2	Simplex Zip	Louis Disbrow	4:39.10
4	Stutz	Dave Lewis	4:40.00
12	Fiat	Joe Matson	4:42.00
7	National	Neil Whalen	4:50.00
21	Chadwick	L. C. Hersey	No time taken
3	National	John Rutherford	Withdrawn

Class E, non-stock, under 301 cubic inches; 50 miles

11	Mercer	Alfred Hummel	54:10.50
5	Case	Joe Nikrent	55:45.00
17	S. P. O.	Howard Plimpton	1:07.10.75
10	Case	Louis Disbrow	Did not finish

Class C, non-stock, 301 to 450 cubic inches; 5 miles

3	National	John Rutherford	4:32.30
4	Stutz	Dave Lewis	4:43.10
7	National	Neil Whalen	4:47.10
6	Schacht	Bill Endicott	5:02.50
1	Berkshire	Harry Grant	Did not finish

Class E, non-stock, 301 and over cubic inches; 100 miles

6	Schacht	Bill Endicott	1:36.41.00
3	National	John Rutherford	1:36.50.10
7	National	Neil Whalen	1:40.05.10

Three cars strike turn at once—National, Fiat and Berkshire

Endicott's Schacht going at 70-mile clip in the hundred

Tetzlaff's Fiat Wins Big Races at Tacoma

Takes 250-mile Free-for-All and Captures 200-mile Heavy Car Race Previous Day

Averages 68.66 Miles an Hour in Latter Race—70,000 Spectators Witness the Five Events

TACOMA, WASH., July 7—The 2-day racing carnival promoted jointly by the Tacoma Automobile Club and the Tacoma Montamara Fiesta committee was run off without accident on the new 5-mile course at Lake View, near this city, with from 60,000 to 70,000 persons witnessing the five road races.

Teddy Tetzlaff, holder of the world's road record, was the star of the meet, driving his Fiat to victory in the heavy-car race the first day and annexing the free-for-all yesterday. In the Friday race Tetzlaff averaged 68.66 miles per hour for 200 miles, while in the 250-mile free-for-all yesterday he averaged 65.8 miles per hour. The medium-heavy car race Friday at 150 miles went to Cooper in a Stutz with an average of 66.6 miles per hour; Pollem in a Mercer took the 150-mile medium-car race at 61.9 miles per hour, while the light-car race at 100 miles was taken by Evans in a Flanders special at 61.1 miles per hour.

Tetzlaff won first place and $3,500 in addition to the Montmarathon perpetual challenge trophy. Bergdoll won second place and $1,000. Devore won third place and $500.

Friday morning's races, although sensational, did not equal the afternoon contests. A series of mechanical troubles resulted in all the cars in the medium-light car class being withdrawn with the exception of the Mercer driven by Pollem. In the light-car class, which was run in connection with the medium-weight car event, there was an especially pretty and thrilling race. Evans in a Flanders special took the lead early in the race and never was headed. Tower, also in a Flanders special, second. The Maxwell, Oakland and Ford finished in the order named.

Tetzlaff won the heavy-car race in the afternoon over forty laps. He won by steady driving on the dangerous curves and bursts of speed on the straightaway stretches. Mulford took the turns at high speed, which tore his tires into ribbons and forced him to go to the pits four times. Finally he came in with a bleeding head caused by a flying stone and relinquished the wheel to his mechanician, Chandler, who finished the race. Tetzlaff went to the pits but once for tire trouble and once for gasoline. The Fiat pit men had excellent team work, while the Knox men were considerably slower.

Hughie Hughes played in hard luck in both days' races, having considerable engine trouble, burning out a clutch on the Mercer in the medium-car event and in the free-for-all he suffered a broken connecting rod.

Great enthusiasm developed in the big event yesterday when Tetzlaff and Mulford held a duel of speed and Tetzlaff won. Mulford's car was fast, but Tetzlaff's tire luck was with him, which was helped by careful driving at the turns. Mulford took these with scarcely a perceptible slackening of speed. Earl Devore's National also was a victim of tire trouble and he was forced to go to the pits three times.

Two Races Run Simultaneously

The two races in the afternoon were run simultaneously. The Mercer, Stutz, National and Pope were in the heavy-car event and all except the Pope kept on after 150 miles were run off and continued in the heavy-car race.

The free-for-all started at 1:30 Saturday with six cars facing Starter Wagner. The Stutz with Earl Cooper at the wheel got away first and the Pope 30 seconds after. Then with ½-minute intervals followed Devore, National; Mulford, Knox; Tetzlaff, Fiat, and Hughes, Mercer. Cooper made the first 5 miles in 4:30. Tetzlaff made a wonderful start and finished the first 5 miles in 4:11.

With a phenomenal burst of speed the Knox took the lead in the sixth lap, when it passed the National in the back stretch, which was made in 4:00. Then followed another 5 miles but 2 seconds slower, and in the seventh Mulford made it in 3:55, a new record over a 5-mile course like that at Lake View.

The Flanders special No. 2, driven by Bob Evans, was first away from the wire in the light-car event and was first to finish, although Evans ran 150 miles instead of 100 and in the loss of the count on one lap he was put into third place by mistake. This was eventually straightened out and Evans given first place. Tower in a Flanders was second and Joermann, Maxwell, third.

Somewhat of surprise was the showing made by the little Ford owned and entered by W. C. Baldwin, of Tacoma. Frank Bennett driving made a good run, but twice tire trouble spoiled his chances.

After the heavy grind the course was subjected to in the first day's events a large crew worked all night and had it in excellent shape for the race on Saturday. The weather warmed up and brought out double the attendance of the first day.

The free-for-all resolved itself into a magnificent contest and a royal one between Tetzlaff in the Fiat, Bergdoll in the Benz and Devore in the National. After having reached a leading position in the nineteenth lap Tetzlaff never again dropped into second place, but all three cars were in the same lap for the last 50 miles and there always was a chance that positions would be altered. Hughes was first off in his wire-wheeled Mercer. The crowd gave him a great send-off and he responded by making the first lap in 4:09. He retained the lead until the third lap, when clutch trouble caused his withdrawal from the race, the third time during the contests.

As Hughes pulled up at the pits he was passed by Cooper in the Stutz, making a 4:19 lap. Cooper held his car there until the eighth, when Bergdoll in the blue Benz rushed by into first place. Cooper succumbed to Tetzlaff in the ninth and held third

OLD ORCHARD BEACH SUMMARIES (Continued)

Special event for mile record

	Jay-Eye-See	Louis Disbrow	39:10

THIRD DAY

Class C, non-stock, 231 to 300 cubic inches; 10 miles

5	Case	Joe Nikrent	9:54.00
11	Mercer	John De Palma	9:59.90
9	Lexington	James Esleck	12:13.00
10	Case	Louis Disbrow	Did not finish

Five miles against time, flying start

2	Simplex Zip	Louis Disbrow	4:04.50

Class E, non-stock, 231 to 300 cubic inches (two races run simultaneously); 25 miles

Class 2-C, 161 to 230 cubic inches

14	E-M-F.	Billy Burke	27:10.80

Class 3-C, 231 to 300 cubic inches

5	Case	Joe Nikrent	25:29.10
11	Mercer	Alfred Hummel	25:37.10
9	Lexington	James Esleck	27:10.80

Class D, non-stock, free-for-all; 10 miles

2	Simplex Zip	Louis Disbrow (new rec.)	8:53.00
18	Bianchi	Charles Vasle	9:32.10
7	National	Neil Whalen	9:40.10
11	Mercer	John De Palma	10:22.00

One mile, flying start, for beach record

	Jay-Eye-See	Louis Disbrow	.36.50.

Class E, non-stock (three races run simultaneously); 100 miles. Race A, 301 to 450 cubic inches; Race B, 451 to 600 cubic inches; Class C, over 600 cubic inches

4	Stutz	Dave Lewis, Race A	1:32.43.60
6	Schacht	Bill Endicott, Race A	1:36.09.00
15	Jackson	Harry Cobe, Race A	1:50.11.50
1	Berkshire	Harry Grant, Race A (90 miles)	1:54.30.00
7	National	Neil Whalen, Race A	Did not finish
16	Fiat	Joe Matson, Race C	Did not finish
18	Bianchi	Charles Basle, Race B	Did not finish

until engine trouble in the twelfth. A series of various delays placed the Stutz fourth and finally fifth in 20 seconds. From that time on the Stutz ran with consistent smoothness. Cooper had finished his forty-fifth lap when the National crossed the wire in third.

Ralph Mulford shared with Hughes and the Cole the bad luck of the day. The Knox driver received an ovation when he started out and when he made the second lap in 4:05 the crowd was frantic. He never passed the grandstand again, magneto trouble putting his car out.

Tetzlaff won his race on his merits. It is not fair to say he outgeneraled the field, but Bergdoll and Devore both drove magnificent races. Tetzlaff made his first lap in 4:26 and his was the fifth car to leave in the eighth. He caught the National in the stretch and jumped in fourth. After Hughes' retirement he ran third, making his best time, 3:59, in the eighth lap.

Bergdoll caught the Stutz on the back stretch in the eighth in view of the crowd, with Teddy's Fiat singing loud behind him. The next lap the Fiat swept past the Cole in front of the grandstand and at the end of the eighth was hard after the Benz, then running in first place and making a pretty race. For 50 miles these positions were retained, with the crowd growing wild as it was perceived Tetzlaff was cutting down the seconds.

In the nineteenth lap the excitement grew to fever heat. The Fiat swept past the Benz, which had traveled a slow lap in 5:49, due to tire trouble, and when Bergdoll spent 7:15 on his lap and tire change Tetzlaff lapped him. At this time Tetzlaff pulled in the pit for gasoline and, as fate would have it, had some trouble in getting the car started. Meanwhile the Benz was speeding along, cutting off the lost lap, with the result that the end of the twenty-second lap found the Fiat just 48 seconds in the lead. Tetzlaff never again fell behind.

When the Benz passed the Verbeck Fiat on the back stretch at 125 miles Tetzlaff's time for that distance was 109 minutes 4 seconds and he was leading by 4 seconds. In the twenty-eighth lap it was noticed the Benz was missing. Chain trouble had delayed him at the bridge for 12 minutes and when he finally passed the grandstand the crowd rose to its feet and gave him a mighty cheer. In the twenty-ninth Tetzlaff came into the pit for tires while the Benz made a 4:17 lap. The Benz after a stop for a broken chain made two good laps in 4:17 and 4:19, but dropped to fourth. In the thirtieth Verbeck was in the pit with engine trouble and Maggio was taken on as mechanician.

Battle Between Tetzlaff and Bergdoll

The thirty-first lap saw Devore second and the second Fiat third until its engine trouble when it went again to fourth. In the next two laps Verbeck made 4:18 and 4:05. The thirty-ninth saw a thrilling lap when Tetzlaff pulled up for gasoline. While the fuel was being taken on the red National rushed by with Devore grinning happily. The raw gas in the exhaust pipe of the Fiat caught on fire and before the car was ready to start the Benz rushed past, thus putting all three cars into the same lap.

Bergdoll was now driving his best and for five laps he and the National had it touch and go. In the forty-fourth Bergdoll made the lap in 4:05 and in the lap following was firmly in second place, which he retained until the finish. He made the best time he could, but Tetzlaff was well away, blazing his trail to the tune of 4:07, 4:06, 4:08 and 4:10, and as the crowd was advised of his progress it rose to its feet and gave the race hero a demonstration as Wagner held the checkered flag for him.

In the forty-fourth Verbeck entered the homestretch just behind the National, swung around it in a wide sweep, followed by the Benz. When he reached the front of the stand Verbeck endeavored to regain the course, but was carried over into the soft dirt near the pits. Just as the crowd held its breath to hear him crash into the pit bars he skillfully brought his car back into the road and was gone.

After this the spectators were frantic and after they had risen and applauded Tetzlaff, the Benz came in for its share. If Tetzlaff was a popular winner Bergdoll also was a great favorite.

All the drivers handled the curves very cautiously in the big event and this pronounced caution explains the very moderate rate of speed averaged even by the winner. Even the fact that it was anybody's race in the last 50 miles did not produce recklessness. This consistency of judgment is what made the Tacoma races remarkable for the lack of catastrophes.

"The Tacoma races were very fast in comparison with many of the records made on famous road courses of the country," said Starter Wagner at the conclusion of the races. "No records were broken, but good time was made throughout, and considering the green condition of the course, the showing was excellent. I will say without any exaggeration, Tacoma has one of the fastest road courses in the world."

The success of the meet is due in no small measure to the following officials: Fred. J. Wagner, starter; Robert E. Magner, who handled the Warner timing device; F. E. Edwards, chairman of the technical committee of the A. A. A.; and Walter Chanslor of Los Angeles, H. C. Mason of Seattle and Harry C. Miller of San Francisco, judges.

With 400 special guards patrolling the entire course outsiders were prevented from approaching within several hundred feet of the track. As a result there was not a single accident.

SUMMARIES OF MONTAMARA FIESTA RACES

FRIDAY, JULY 5

Light cars, purse $1,000, 100 miles

Pos.	Car	Driver	Time
1	Flanders Special	Evans	1:38:20.00

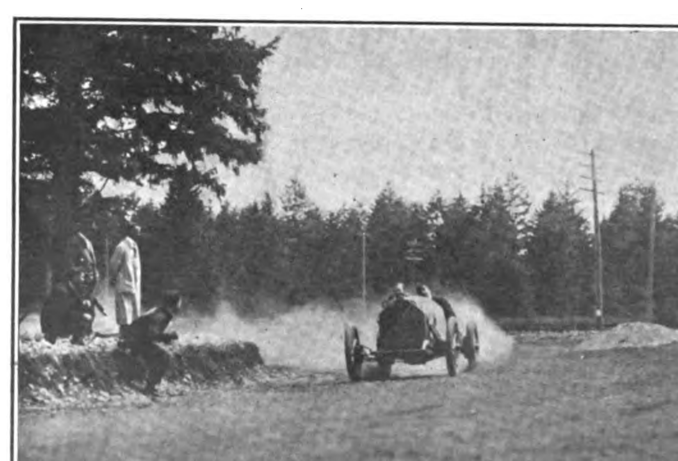
31	Knox	Mulford	Out 2d lap



Tetzlaff taking one of the turns on the Tacoma course

American Wins Road Run

Driven by Ralph D. Earle, Captures Honors in Wildwood Test—Prizes of all Descriptions

Several Ladies Compete—Sixty-three Cars Start—Builders of Indianapolis Speedway Honored

WILDWOOD-BY-THE-SEA, N. J., July 3—Ralph D. Earle, of Philadelphia, driving an American car, captured first prize today in the roadability run from Camden to this resort held under the auspices of the combined Boards of Trade of Wildwood, North Wildwood and Wildwoo Crest. Earle's time for the 108 miles was 6 hours 22 minutes 40 seconds, which was within 35 seconds of the secret time set by Mayor J. Thompson Baker, of Wildwood—6 hours 23 minutes 15 seconds. The prize was $50 in gold.

Second prize, the Hotel Ridgway cup was won by F. P. Keeley, Case car, who finished 1 minute 13 seconds out of the way, his corrected time being 6 hours 22 minutes 2 seconds. M. R. Faulkner, Michigan car, captured third prize, the Colonial Hotel cup, Wildwood, in 6 hours 24 minutes 29 seconds, 1 minute 14 seconds slower than the secret schedule, and fourth prize, the Hutchinson Motor Company cup, Woodbury, was carried off by a woman driver, Mrs. C. V. R. Caldwell, in a Premier, time 6 hours 20 minutes 30 seconds.

In addition to the main prizes awarded to winners for the full distance there were supplementary running premiums for the drivers finishing nearest the schedule set for the intermediate controls, of which there were four. The Alloway Hotel cup, Alloway, N. J., offered as the first control trophy, was captured by N. A. Koch, driving an Interstate car, who checked in 51 seconds ahead of the scheduled time. Car No. 35, a Case, driven by Henry Fallows, won second prize, the Nelson House cup, Salem, N. J., he arriving at the latter town within 1 minute 18 seconds of the allotted time. Third control prize, the Bridgeton cup, also went to the Interstate car, but 2 seconds out of the way. The Ruric Hotel cup, fourth control prize, was won by W. Eldredge, driving a Garford.

Half a Dozen Ladies Take Part

In the special division for women only, of whom about half a dozen competed, two prizes were hung up, a sterling silver chatelaine bag for first and a sterling silver chatelaine wrist watch for second. The former was taken by the winner of the fourth prize in the main division, Mrs. C. V. R. Caldwell, time 24 minutes slower than schedule, the second prize by Miss Anna E. Verga, Kisselkar, 34 minutes 50 seconds slow. Mrs. Sarah Hoffman, Ford car, was third, 50 minutes 47 seconds slow.

In addition to the above prizes and trophies a special purse of $50 was set aside for the Philadelphia dealer having the greatest number of cars of any one make entered in the run. This was awarded to the Case with 10 cars in line.

Of a total list of 84 entries, 63 cars left the new Hotel Ridgway, Camden, this morning at irregular intervals between 9 and 11 o'clock. Of this number nearly a score were racing cars which figured in the roadability run as non-contestants for prizes, being entered in the Independence Day races on the Wildwood speedway. A baggage truck carried participants' luggage and a tire car followed in the wake of the train to provide first aid to the injured, the help of which was frequently sought.

Especial interest attached to the women's division of the run, supervised by Mrs. D. Walter Harper, and at every control the fair contestants were given an ovation. Mrs. C. V. R. Caldwell, driving a Premier car, monopolized the glory in this section, for she not only won first ladies' price but also captured fourth prize in the main division. The list of participants follows:

Car	Driver
American	Ralph D. Earle
American	William Thiellens
American	W. L. Jones
American	George M. Rubelli
E-M-F	Adolph E. Beldner
Stoddard-Dayton	Charles Veith

Speedway Builders Honored

INDIANAPOLIS, IND., July 8—The people of Indianapolis last Tuesday night paid tribute to the living for what they have accomplished for their home city, when they gave a complimentary dinner at the German House for Carl C. Fisher, James A. Allison, Arthur C. Newby and Frank H. Wheeler, owners of the Indianapolis Motor Speedway.

There were about 150 guests present, including many prominent in the business and professional life of the city. Each of the guests of honor was presented with a copy of the following resolution, signed by each guest present:

"We, the undersigned, citizens of Indianapolis, very much desire to express to our fellow townsman and friend, our sincere appreciation of his magnificent work in furthering the best interests of our city. In thus acknowledging his worth, we congratulate him on his great accomplishments, wish him further unbounded success and promise him our hearty support and co-operation.

"We consider it a distinct privilege to publicly express, at least in part, those sentiments of high regard and esteem which, individually, have always been entertained by the people of our city, who have watched with close attention the magnificent growth of his unparalleled enterprise."

Grand Prix Distance Shortened

MILWAUKEE, WIS., July 7—A campaign to secure a really representative field of foreign-built cars and foreign-born drivers for the grand prix race in Milwaukee on September 17 is now being made by a special committee of the Automobile Club of America through its European representatives, the Automobile Clubs of France, Italy, Belgium, Switzerland, Canada, Austria, and R. A. C. of Great Britain and Kaiserlicher of Germany.

There are excellent chances that George Boillot, winner of the French Grand Prix, June 25 and 26, will bring his Peugot to America to compete at Milwaukee. Likewise hopes are given that Victor Hemery will come over with a Lorraine-Dietrich, while it is sure that Louis Wagner will drive one of the three Italian Fiats which will be entered, the team which worked together in the Dieppe race to be kept intact for Milwaukee.

There has been a slight change made in the conditions for the running of the Grand Prix, the distance being cut from 50 laps to 47 laps of the 8.725-mile course, making the mileage of the feature event 409.075 instead of 436.25 as originally announced.

The road work is progressing satisfactorily and the course already shows much improvement. The placing of the start and finish line will not be done until the various straightaways are in a completed condition.

Fast Time at Wildwood

Freitag's Fiat Covers the Mile Straightaway in :43 2-5, Closely Followed by Menker's Klinekar

Buick Wins Handicap and 161-230 Event, Klinekar the 301-450 and Mercer the 231-300

WILDWOOD-BY-THE-SEA, N. J., July 4—The success of yesterday's roadability run to this resort was second only to that which attended the speed trials held this afternoon over the 1-mile straightaway course, which brought the 2-day carnival to a close.

A long time before the scheduled hour of starting an immense throng gathered along the speedway. The fact that it was an unusually hot day and that a majority of the spectators were compelled to stand in the sun did not act as a deterent. Both sides of the course for a distance of over a mile were lined with a perspiring crowd and the temporary grandstand erected, affording practically the only protection from the sun's rays, was taxed to capacity.

The contestants were for the most part Philadelphians who came down yesterday on the roadability run as non-contestants in that event. The program was a well-balanced one and the finishes were so close in a majority of cases as to keep interest keyed up till the finish. The large crowd was well taken care of, not an easy matter in the case of a course like the one here, where the temptation is to break out into the roadway in order to catch a glimpse of the cars coming, subjecting the over-enthusiasts to danger from the speeding machines; but the guardians of the course were on the alert and not a single accident occurred.

A feature of the meet was the dispatch with which the events were run off. Clarence W. Cranmer, secretary of the Quaker City Motor Club, starting judge of yesterday's run, acted in the capacity of starter and the races were completed without the irksome delays between heats that marred some of the races held here two years ago.

Fiat and Klinekar Divide Honors

Speed honors of the day were divided between William Freitag, in the Fiat, who in the trials for the one-mile record, flying start, negotiated the distance in 43 2-5 seconds, and John Menker, Klinekar, who made the fastest mile of the afternoon in a race, 55 seconds, in event No. 3. The record established two years ago by the Chadwick car remains unbroken, however, as at that time a mark of 41 seconds was hung up by the Chadwick.

Eddie Bauer, driving a Buick, proved the most consistent winner of the meet, capturing first place in event No. 1, the first heat and race in the final time trials. In the initial event Bauer was given a close rub by H. Baker, driving a Cartercar, the latter being only a car's length behind at the finish.

Harvey Ringler had a walkover in the second event, winning from C. C. Fairman, Klinekar, by the safe margin of 21 seconds. John Menker, Klinecar, cut loose in the third race and made the fastest mile of the day outside of the record trials. Menker finished in 55 seconds, his nearest competitor being Philander C. Knox, Jr., 9 4-5 seconds behind.

Preceding the races this morning was a "happy-go-lucky" run for ladies conducted by Mrs. D. Walter Harper. All cars were driven by women over a specially marked route through Wildwood and Wildwood Crest, with women passengers and officiated over by women.

Over at the sister resort of Cape May today 32 pleasure cars and 7 commercial vehicles paraded through the resort, prizes being awarded for the best decorated cars.

Summaries of the races here today:

Division 2-C, non-stock, 161 to 230 cubic inches

No.	Car	Driver	Time
1	Buick	Eddie Bauer	1:15 3/5
2	Cartercar	H. Baker	1:16 4/5
3	Empire	R. S. Smith, Jr	1:19 1/5

Division 3-C, non-stock, 231 to 300 cubic inches

1	Mercer	Harvey Ringler	1:08
2	Klinekar	C. C. Fairman	1:29

Division 4-C, non-stock, 301 to 450 cubic inches

1	Klinekar	John Menker	:55
2	National	P. C. Knox, Jr.	1:04 4/5
3	G. J. G.	W. C. Thiebaud	1:08

Time trials, free-for-all

1	Fiat	Wm. Freitag	:43 2/5
2	Klinekar	J. Menker	:46 2/5
3	Chadwick	C. F. Stretch	:50
4	Apperson	Geo. Davis	:53 4/5
5	National	P. C. Knox, Jr.	:56 1/5
6	Benz	S. Wood	1:00 3/5
7	Marion	E. G. Harris	1:04 2/5

Free-for-all handicap, first heat

First heat

1	Mercer	Harvey Ringler	1:06 4/5
2	Marion	E. G. Harris	1:12 1/5
3	Chadwick	C. F. Stretch	1:19 1/5

Third heat

1	Apperson	Geo. Davis	1:06 1/5
2	Fiat	Wm. Freitag	1:06 4/5

Final heat

1	Buick	Eddie Bauer	1:15
2	Apperson	Geo. Davis	1:15 2/5
3	Mercer	Harvey Ringler	1:16 2/5

Special event

1	Marion	E. G. Harris	1:08
2	American	Ralph D. Earle	1:17

Rules for Farm and Ranch Run

AUSTIN, TEXAS, July 8—The motor car run from Dallas to San Antonio and return, which is to start July 22, and return to Dallas July 27, to be conducted under the auspices of the Texas Farm and Ranch Publishing company of Dallas, is attracting much attention not only among the people of Texas but other parts of the country. It is said to be the first event in which only farmers and ranchmen living on their own farms and ranches and driving their own cars are eligible as entrants.

The eligible cars embrace any touring car or runabout. Cars shall be divided into two classes according to body equipment, as follows:

Touring Car Class.—Touring cars shall be divided into seven divisions of Class A as follows:

Division 1 A, $800 and under; division 2 A, $801 to $1,200; division 3 A, $1,201 to $1,600; division 4 A, $1,601 to $2,000; division 5 A, $2,001 to $3,000; division 6 A, $3,001 to $4,000; division 7 A, 4,001 and over.

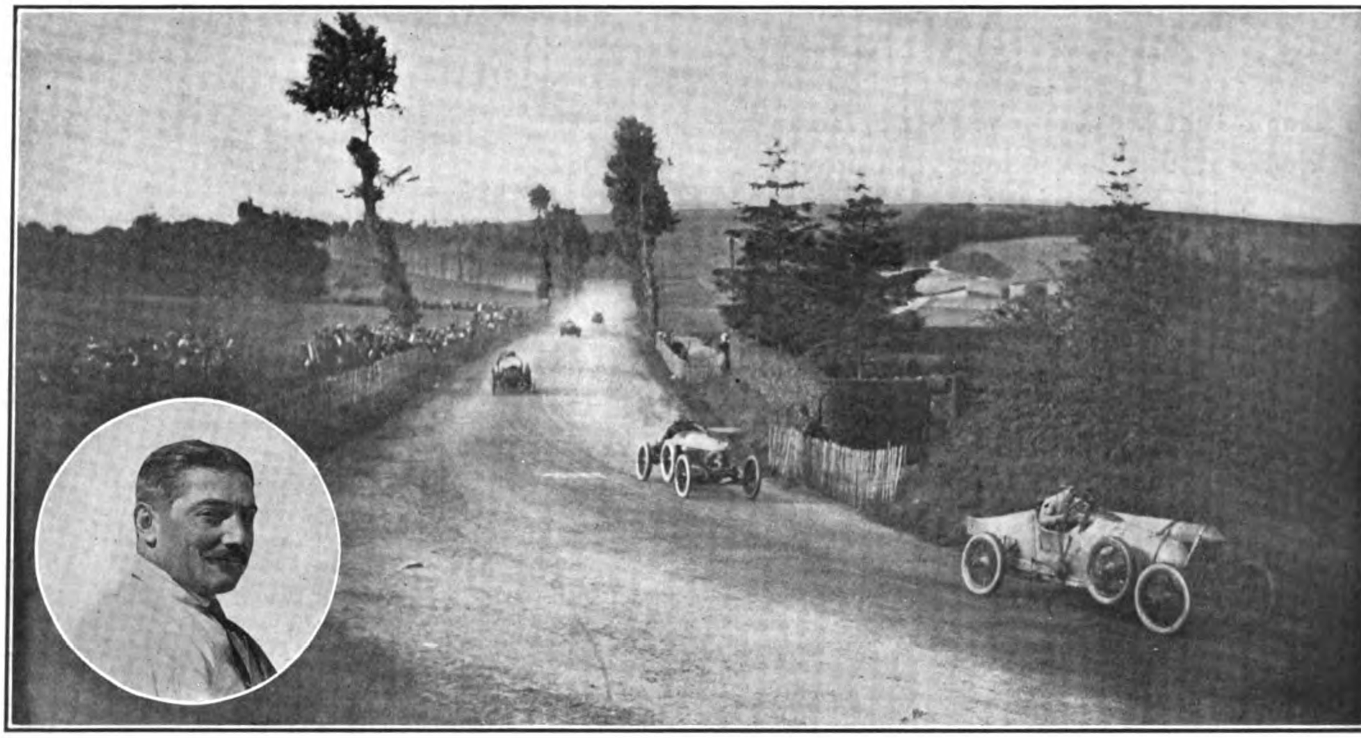
Runabout Class.—The runabouts, miniature tonneaus, surreys and single or double rumble-seated cars shall be divided into seven divisions of Class A as follows:

Division 1 A, $800 and under; division 2 A, $801 to $1,200; division 3 A, $1,201 to $1,600; division 4 A, $1,601 to $2,000; division 5 A, $2,001 to $3,000; division 6 A, $3,001 to $4,000; division 7 A, 4,001 and over.

The speed of contestants is: Division 1 A, 14 miles per hour; Division 2 A and 3 A, 16 miles per hour; Division 4 A, 5 A, 6 A, 7 A, 18 miles per hour.

Four States Tour Is Well Under Way

INDIANAPOLIS, IND., July 9.—Thirty-three cars got away on the second annual Indiana Four States Tour this morning. The first night control will be Ft. Wayne, Ind. A farewell smoker was given the participants in the tour by the members of the Hoosier Motor Club last evening. The tour, which is through Indiana, Ohio, West Virginia and Kentucky, is to last 16 days. It is non-competitive. Seventeen Indiana factories are represented in the cars taking part in the run.



Five cars in view at one time, approaching the village of Eu. (Circle) Boillot, who drove winning Peugeot

Grand Prix Aftermath

Bruce-Brown in Fiat the Virtual Winner, Although Deprived of Laurels by a Vicious Rule

Real Honors of the Race Captured by Sunbeams—Event a Failure from the Viewpoint of Attendance

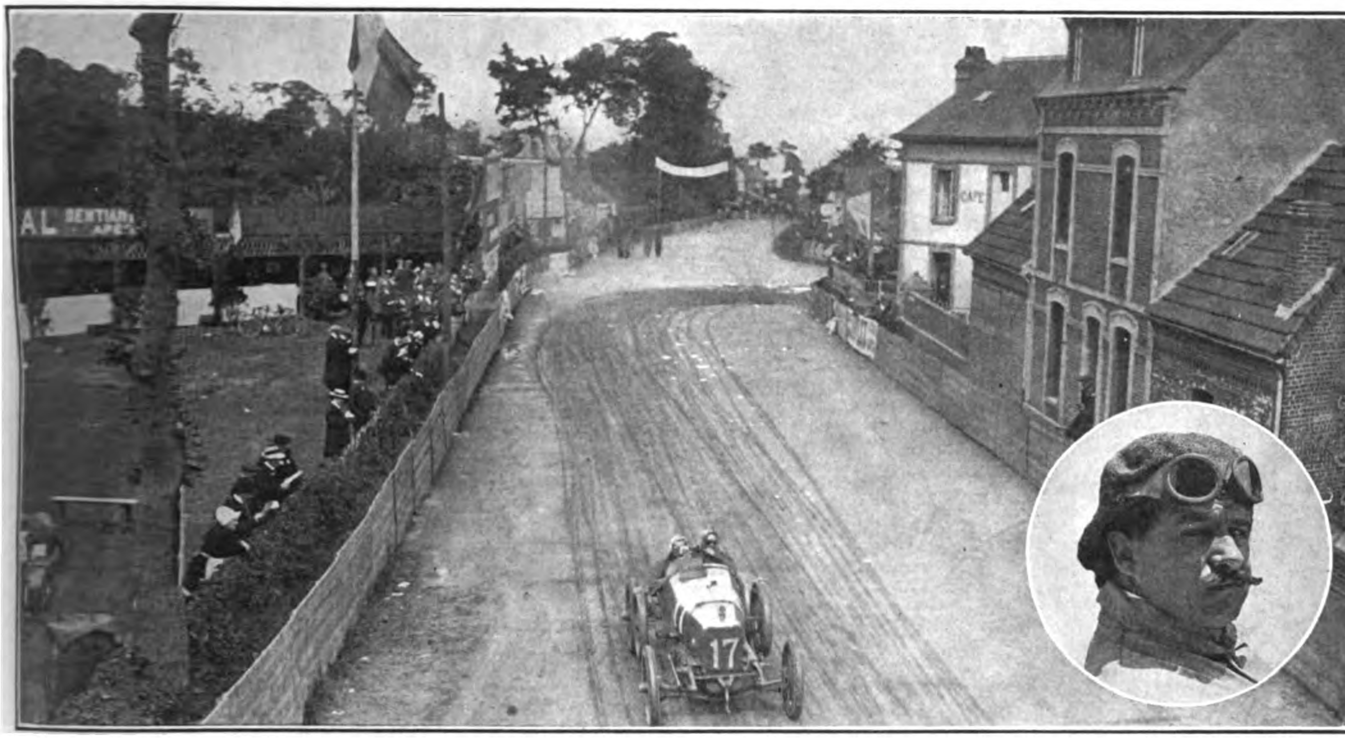
AS had been ardently desired by its organizers, the dual race held on the Dieppe circuit June 25 and 26 turned out before it ended—though with but a skinny chance between successful consummation and dire failure—a love feast celebrating and cementing the cordial understanding of England and France and a move on the chessboard extending this understanding to the English and French automobile industries, but it has not yet been charged that the wish in this case was the father of the result. Nobody has dared to insinuate publicly that the nut which came loose on the second day, spilling the gasoline of the car which stood to win, had been helped over night by an over-zealous patriot to prevent an Italian manufacturer and an American pilot from carrying away the first honors. But this charge is certain to be made in private, since trade animosities had been aroused with regard to the event and German, Italian, Belgian and American manufacturers had practically boycotted it, refusing to second the belated effort of the French industry for re-establishing its former prestige.

It is admitted, however, in the French press that the rule under which Bruce-Brown was prohibited from replenishing his tank more than once during the day's run, though the leakage compelling him to stop carried its own punishment in form of delay, should be amended, being too likely in another instance to turn a virtually earned French victory into unprofitable though not inglorious defeat. *L'Auto* in its issue of June 27 admits that Bruce-Brown should have won the Grand Prix, but consoles its sense of justice by the consideration that the Peugeot car which Boillot, with the aid of the accident, drove to victory, did not only beat the two other Fiat cars in the race on merit alone, but exemplified superior and more modern construction, in so far as the cylinder volume of its motor was only about one-half of the cylinder volume of the disqualified Fiat car, while the weights of the vehicles did not differ materially.

The classification of all the vehicles which finished in the double race is given in the appended table, from which it is seen that the racing interest is exhausted with the performances of the Peugeot car, the two Fiat cars, the Sunbeam team and the

General view of the start and portion of grand stand

De Palma in Fiat passing grand stand at 75-mile clip



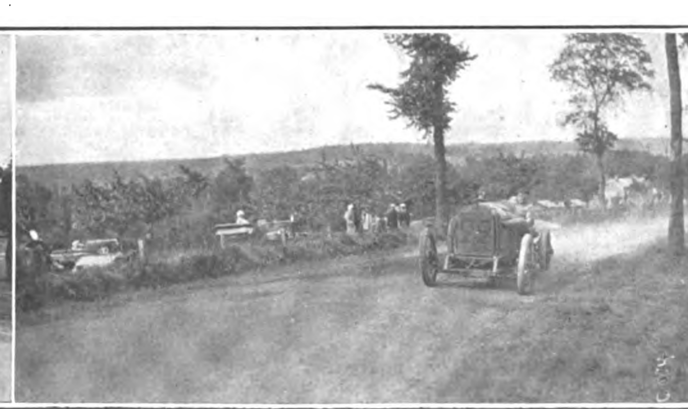
Just beyond the acute-angled turn at Dieppe corner of course. (Circle) Rigal, who drove winning Sunbeam

Belgian Excelsior car driven by Christiaens, the latter being the only six-cylinder car in the race. The others who finished proved regularity at a more moderate speed, and this in the case of the diminutive Mathis car, built at Strasburg and the only German car entered, and in that of the Côte car, whose two-cycle motor required a public demonstration to inspire faith, was a matter of more than commercial interest. The largest share in the racing glory, viewed with an eye to the art of the drivers, the merit of construction and workmanship and the commercial significance—all in one comprehensive glance—goes by unanimous consent to the Sunbeam team that wins the cup for team regularity and with four-cylinder motors of a total cylinder volume of only three liters come within one-half hour of equaling throughout a distance of 1,550 kilometers the speed attained in the unlimited class with motors five times as large. France takes to herself some of this glory of the English manufacture, claiming Louis Coatalen, the chief engineer of the Sunbeam factory, as one of her sons. The merit of the Sunbeam car, says Mr. Faroux in *L'Auto,* lies more in a wonderful workmanship and finish than in any new or extraordinary features of design.

Several cars which were in line for success at the end of the first day are found wanting in the final line-up. De Palma was found to have replenished his fuel against the rules, being in company in this respect with Goux, one of the Peugeot team, who was far behind his colleague Boillot in speed, however, and both De Palma and Goux were counted out. The fast Gregoire cars were withdrawn, out of respect for the dead, when Bassaguana, mechanic to one and brother-in-law to another of the Gregoire drivers, had been killed in the only fatal accident of the event. The Rolland-Pilain car was well up in the race on the first day, driven by Anford and leading De Palma by three minutes, but at the start of the second day Anford's mechanic was incapacitated by fatigue, the spark plugs were found to be fouled, and Anford, in attempting to remedy this trouble, got the wires crossed and was unable to start the car. Pilain was called to assistance, at once discovered the crossing of the wires and corrected it with his own hands. According to the rules, this spontaneous act rendered it necessary that Pilain should himself do the driving, and while he did so he was not fit for the task and lost the place earned for his car in the race.

With regard to the performance of the Fiat team, it is brought out as one of the peculiarities which may develop in an event which is spread over two days that, though Boillot came out winner for both days, he was second to Brown on the first day and also second to a Fiat car on the second day, Wagner beating him more decisively on that day than Brown had done at the opening. As the event was intended as a trial for teams, with a view to bringing into relief the comparative merits of manufacture rather than the skill of drivers, it is considered an anomaly that the Peugeot team, two of which fell behind and did not

Start of Goux's Peugeot. Note how crowd encroaches



The winning Peugeot on the last lap of the big race finish, could come out ahead of the Fiat team though beaten each day by one of them.

The attendance at the race was very meager, and *Omnia*, June 27 issue, comments upon the complete failure of the organizers in arousing popular enthusiasm. People are tired, says the editor, of having it demonstrated to them that the highest speed can be produced more readily by 200 than by 20 horsepowers. They want to know what the speed costs. Hence the construction of racing vehicles should be entirely optional, the distance should guarantee its robustness, and the winner should be he who produces the greatest speed for each liter of fuel consumed. On this basis, he thinks, racing might be revived in France.

FINAL OFFICIAL CLASSIFICATION OF CONTESTANTS
For Grand Prix of the A. C. F.

	h.	m.	s.
1. Boillot (Peugeot)	13	58	02⅗
2. Wagner (Fiat)	14	11	08⅖

Market Changes for the Week

The market for materials pertaining to the automobile industry showed no important changes this week so far as prices were concerned. Steel remained unchanged, with the active business continuing. Among the largest orders was one for 3,000 tons placed by a radiator manufacturer in New England. Copper and tin were weak, the latter decidedly so in consequence of a panic in the London market for this metal.

Gasoline, after having risen to 20 cents last week, remained at this price. Other oils and lubricants remained also at their former quotation. Rubber showed the same strength it had displayed for the last fortnight and a fair business was done at $1.12 for Fine Up-river Para rubber. Tire scrap advanced 1-2 cent a pound.

Legal News of the Week

Receiver Asks Permission to Sell Plant of Atlas Engine Works—Testimony Taken in Prest-O-Lite vs. Searchlight—Oil Company Bankrupt

INDIANAPOLIS, IND., July 9—A petition has been filed in the Superior Court by Fred C. Gardner, receiver for the Atlas Engine Works, asking permission to sell the property. The petition will be passed on Thursday. Mr. Gardner says that the company's liabilities exceed $100,000, that it would be impossible to obtain sufficient money to operate the plant and that to close the plant would mean a considerable loss. An inventory of the company's property has not yet been completed. The receiver has been authorized by the court to borrow $25,000 to meet the payroll and for current expenses.

Prest-O-Lite vs. Searchlight

CINCINNATI, July 3—Earl W. Griffin, as special master in the infringement suit of the Prest-O-Lite Company *vs.* the Searchlight Gas Company of New York and Coughlin & Davis, of this city, today took testimony in this case at the Sinton Hotel. Victor Gluchowsky, a member of the firm of Coughlin & Davis, was the principal witness, his testimony relating to the business of the firm in Prest-O-Lite and Searchlight tanks for automobiles. Winter & Winter, of New York, represented the complainants, and Herrlinger, Dixon & Stewart, of this city, represented the defendants.

Independent Refiners Sales Co. Bankrupt

A petition has been filed by the Oil Products Company of New York City to have the Independent Refiners Sales Company of the same city declared bankrupt. The indebtedness of the company is said to amount to about $10,000 and the assets to about $6,000. An offer was made recently by the company to pay off the creditors on a percentage basis, but it was decided that more money could be obtained by bankruptcy proceedings.

Decision Pending in Taximeter Suit

The suit of the American Taximeter Company *vs.* John Hefferon, John Kavanaugh and the International Taxameter Company of America was argued in the New York Supreme Court on Monday, July 8. Decision will probably be handed down in the near future.

The motion in the case is to enjoin Hefferon and Kavanaugh from hiring or using taximeters of any make other than the Jones taximeter, of which the plaintiff, as assignee of the patent, is the exclusive agent for the United States, and to enjoin the International Taxameter Company of America from leasing to them any make of taximeter.

Saul S. Myers argued for the plaintiff and Jacob A. Cantor appeared for the defense.

Horn Suits Not Filed Until July 3

Based on information received from G. V. O. Lansing, president of the Aermore Manufacturing Company, Chicago, Ill., THE AUTOMOBILE on June 27 stated that this company filed a bill in the United States Circuit Court, Chicago, against the New Era Manufacturing Company, charging infringement of patent No. 1,015,595, owned by the Aermore Company. Upon investigation in the courts it was discovered that this bill was not actually filed until July 3, although Mr. Lansing was notified June 18 by his attorneys that such bill had been already filed.

Demonstrations Are Passé

So Says Vice-President of the Willys-Overland Company—Thinks They Are Graft on the Part of Joy Riders—Gramm in New Company

TOLEDO, O., July 8—"That demonstrations are a thing of the past was evidenced during the Overland District Managers' Convention held recently at the Willys-Overland plant at Toledo," said Vice-President Bennett in a recent interview. "It was not the consensus of opinion that 'demonstrations must go' but that 'demonstrations have gone.' It has been a time-honored custom since the inception of the motor car to give demonstrations to prospective buyers, so that the purchaser might know what his car would do. In the olden days of the horseless carriage demonstrations were imperative because no one was sure how far a car would run without a breakage of some sort. Today the buyer knows what an automobile can accomplish (providing he is selecting a standard make) and does not ask nor require a demonstration. On the other hand demonstrations have been a "graft" on the part of joy riders and a drainage on the dealer. Many a person has entered a salesroom, feigning an interest in a car when the sole object was to secure a ride. The present-day motor car has time and again conclusively demonstrated that it will go anywhere and everywhere, surmount almost any obstacle, climb the steepest grades, and wallow through mud, sand and snow—that is why the public does not need to be shown."

Gramm in New Truck Company

LIMA, OHIO, July 6—The Gramm-Bernstein Company of Lima, Ohio, has been incorporated with a capital stock of $500,000 of which $200,000 is preferred 7 per cent. accumulative stock for the purpose of manufacturing motor trucks. The officers of the company are Max Bernstein, president; B. A. Gramm, vice-president and general manager; Harry O. Bentley, secretary and Fred Bizantz, factory manager.

This organization places Mr. Bernstein in charge of the financial affairs and Mr. Gramm in charge of the manufacturing and sales end. There will be a sales manager and an expert in charge of the publicity department.

The company has awarded the contract for new roofs to the buildings to be occupied by the concern. Factory Manager Bizantz is preparing specifications for the new machinery to be installed. The plant was formerly occupied by a paper mill.

First Lion Car Ready in 2 Weeks

ADRIAN, MICH., July 8—The Lion Motor Car Co., whose plant was totally destroyed by fire June 2, has been reorganized and within 2 weeks the first car will be ready for demonstration. It is announced that the new factory will be ready within 90 days. The Industrial Association of Adrian guaranteed $100,000 to keep the factory in the city. The Wing & Parsons Company has been taken over by the Lion Motor Car Company. The new factory is of increased size, covering 6 acres.

Stewart Motor Corporation Formed

BUFFALO, N. Y., July 8—At a special meeting held last week by the directors of the Stewart Motor Corporation, just incorporated here with a $250,000 capital, T. R. Lippard was chosen president and general manager of the new concern, while R. G. Stewart was selected as vice-president and chief engineer. R. P. Lentz, of Hartford, Conn., was chosen treasurer and secretary, while Robert W. Ingersoll, manager of the Firestone Tire and Rubber Company of Buffalo, will be sales manager for the new concern.

The latest addition to Buffalo's automobile industry has leased the large plant formerly occupied by the Niagara Machine and Tool Works at Jefferson, Superior and Randall streets for the transaction of their business. The new corporation also will occupy the four-story brick structure adjoining this plant and the power plant in the rear. Extensive improvements and alterations are being made on the building and orders are being placed for new equipment and machinery. Offices have been opened at 1056 Ellicott Square.

The Stewart Motor Corporation will engage exclusively in the manufacture of light capacity motor trucks. Arrangements are being made to have new trucks ready for delivery by September 1 and orders are being taken now for delivery at that time. About fourteen various makes of trucks will be made by the Stewart company, the maximum capacity of the trucks being about 1,500 pounds.

Republic Motor Company Formed

A large piece of property has been acquired by the Republic Motor Company, of New York, on Eleventh avenue between Fifty-sixth and Fifty-seventh street. It is the purpose of the company to build cars and sell them through a factory selling organization. The company has been incorporated under the laws of the state of New York. It is under the management of W. C. Durant, who, when interviewed by a representative of THE AUTOMOBILE, said: "This is the first of a series of ten factories to be put up by separate companies in different large distributing centers to build cars which will be especially adapted for their particular locality." The other cities selected are Philadelphia, Boston, Cincinnati, St. Louis, Minneapolis, Portland, Ore.; San Francisco and Los Angeles.

Automobile Securities Quotations

No startling developments were witnessed in the automobile department of the stock market during the past week. While no general trend made itself felt, the majority of securities advanced to a moderate degree. Some consolidation talk of the street relating to a possible merger of various tire manufacturing interests brought about advances in several issues of this class, notably in Goodyear stock, which rose 40 points. Automobile manufacturing securities changed little if any in their quotation, the most important advance being one of 9 points in the case of the Garford stock. The tone was steady and the volume of dealings satisfactory. Following table shows the prices this week in comparison with those of 1911 at the corresponding time:

	1911		1912	
	Bid	Asked	Bid	Asked

Trade News of the Week

Death of A. W. Harris, Oil Manufacturer, a Severe Blow to the Entire Automobile Industry

Matheson Affairs Finally Settled and Company Now on a Sound Financial Basis

THE entire automobile industry will mourn the loss of A. W. Harris, president and general manager of the A. W. Harris Oil Company, Providence, R. I., who died on Sunday, June 30, after a short illness. Not alone will his loss be felt in business circles, but throughout a wide social acquaintance as well.

Mr. Harris was a gentleman of education, having taken his degree at a prominent American institution of learning. The reputation for integrity which characterized his business dealings extended as well to his social intercourse.

In the early eighties Mr. Harris began the manufacture of high-grade steam engine and cylinder oil, building up what he characterized as his "smokestack" business until he was among the leaders in that line. When the automobile industry first began to attain prominence, more than a decade ago, Mr. Harris was one of the first to enter the field of supplying high-grade lubricants for gasoline motors.

So insistent was Mr. Harris on keeping up the quality of his product that the name Harris has always been a synonym for the highest standard in the lubricating oil field. The result has been that Harris oils are recognized throughout the world as among the best on the market.

Mr. Harris descends from a long line of Americans who have done things in the mechanical world. His uncle, William A. Harris, was one of the builders of the famous Corliss engine.

The main business office and factory of the A. W. Harris Oil Company are located at Providence, R. I., and there are branches in most of the principal cities of the country, its product being equally as well known in the Far West as it is in the Eastern section of the country. Mr. Harris leaves a wife and daughter.

Matheson Accounts Cleaned Up

When the Matheson Automobile Company, Wilkes-Barre, Pa., extended its capital to $2,650,000 2 years ago and took in the Matheson Motor Car Company, which was at that time in the hands of a friendly receiver as the result of a suit in equity brought by F. M. Quimby et al., about 2 per cent. of the creditors did not immediately obey the court order which declared for an adjustment on a basis of 50 per cent. stocks, 25 per cent. bonds and 25 per cent. cash. These creditors held back with an idea of obtaining all cash. The accounts have now been cleaned up and the reecivers are to be dismissed. The Matheson Automobile Company has been uniformly successful and has been working continually on a sound financial basis.

Sales Managers' Convention Postponed

The convention of sales managers to be held under the auspices of the Automobile Board of Trade will probably be put over until some time in September. Many of the sales managers are away on their vacations at the present time and a better attendance may be expected at that time of the year.

Car Designed on Dachshund Lines

St. Louis, Mo., July 8—A new car, to be called the Shomee-Dachshund, is to be made in St. Louis, by a company backed wholly by local capital. The name comes from the famous Missouri expression; "Show me." A dachshund is to be on the front of the radiator.

The car is to take a dachshund for a symbol because of its low center of gravity and low appearance. The machine will be overslung, and yet the designer, a St. Louisan, claims that the center of gravity will be lower and that it will have a lower appearance than an underslung car.

The machine will sell at about $1,800, will have Bosch and Atwater Kent ignition, left side drive, 120-inch wheelbase, dry multiple disc clutch, full floating rear axle, Continental engine, Rayfield or the designer's own carburetor and demountable rims. The first car is nearly finished. If it works right with a try-out the machine will be immediately put on the market.

An option on a factory site has been secured and 500 cars will be put out the first season.

Abbott Adds Four District Managers

Detroit, Mich., July 9.—The sales force of the Abbott Motor Company has been strengthened by the addition of four district managers. E. D. Hand, who resigned recently as assistant sales manager of the E. R. Thomas Motor Company, has been given the states of Ohio, Pennsylvania and West Virginia. S. T. Henderson, who was formerly with the Bergdoll Motor Car Company, has been given the management of the sales for a number of Southern states, with headquarters at Atlanta, Ga. F. E. Westcott, formerly representative of the Reo Motor Car Company, assumes the control of the Indiana and Kentucky output. J. E. Warren, who has been connected with the Chalmers Motor Car Company for the past 4 years, takes charge of the Pacific Coast sales as special representative.

S.A.E. Meeting to Be in September

There will be no meetings of the metropolitan section of the Society of Automobile Engineers during July and August, the next meeting being scheduled for the last Thursday in September. Work is being pushed forward on the 1912 transactions which are expected to be ready during the latter part of this month.

Outdoor Show for Mound City

St. Louis, Mo., July 8—Beginning October 8 and ending October 14 the St. Louis Automobile Manufacturers' and Dealers' Association will give its second annual fall outdoor automobile show at Forest Park Highlands. This is the sixth annual show given by the association. Forest Park Highlands, a great summer resort in the heart of the city of St. Louis, has had a large sum of money spent upon its improvement this year, which improvements were made at the suggestion of the automobile trade of St. Louis in order to better suit the big resort for their purposes. The show held at the same place the first week in October, 1911, was a brilliant success, and the plans of the committee contemplate novel methods of advertising which will assure a larger attendance and greater success than last year. The show is open to all St. Louis dealers in automobiles and to accessory trade located anywhere. The show committee appointed consists of H. B. Krenning of the Dorris Motor Car Company, John C. Anderson of the Ford Motor Company, John Phillips of the Phillips Auto Company, Samuel Breadon of the Western Automobile Company, T. L. Houseman of the Overland Automobile Company and Frank R. Tate of the United Motor-St. Louis Company.

Suits have been filed in the United States District Court by the Enterprise Automobile Company for alleged infringement of Dyer patents, Nos. 885,986 and 921,963, against John H. Hooper, Michael J. Bird, Washington Garage Company, David Rumsey, Alexander Krull, Ludwig Kraus and James Barnshaw.

Car Painting Not Costly

Renovating the Automobile No Longer The Expensive Proposition It Was In the Early Days

How Work May Be Done at a Minimum of Cost —Dressing Anew the Accessories

EXPENSIVE painting of the automobile is not always necessary. Plenty of good painting may be done and, as a matter of fact, is being done on a lower cost basis than at first glance may appear possible.

In some way the car owner has come to believe that the painter is an expensive man to visit when painting repairs are needed. Such is contrary to the facts, considering the value the painter is expected to give, and, indeed, does give.

One of the important items of expense attached to the painting of the car is that covering the cleaning up and making the car ready for the painter. To this extent the owner of the car can save himself, for it is manifestly cheaper for him to have the main part of the cleaning up done prior to taking the car in for repairs.

When the automobile was making its sensational entry into the world it was deemed wise to perform a lot of unnecessary operations upon the paint and varnish surface once the car came within the confines of the paint shop. The owner of the car, apparently to keep up appearances and add to the gayety of the situation, came bravely to the front and demanded that all things be done unto the machine to make it one of the finest, regardless of cost. Reasonably enough, he got what he demanded, and quite naturally paid plenty enough for it.

Cheap Work Not Necessarily Bad

But the former things have passed away and today most excellent painting is being applied to the car at a price, generally speaking, which a few years ago would have given everybody concerned a serious case of heart trouble.

To be sure, the automobile, when compared with the horse-drawn vehicle, is at the minimum figure a formidable proposition. However, as stated at the outset of this article, good painting can be done and is being done at reasonable cost.

The surface of the car when it shows a varnish film practically intact, with nothing more serious than shallow checks, is in no condition to need a series of primary coatings, unless the car is above the average and the owner is very willing to pay for non-essentials.

Simply lay hold of the body of the car and put it through a hard cleaning process, scouring all the grease flakes and sandpapering the surface. Surface dents and fractures should get a touch of some good lead and oil paint, and as soon as they have dried putty up with a hard drying putty. The day after scour all putty smears down level with the surrounding surface, using a block of rubbing brick dipped in gasoline.

Then select the body color, dust off and apply color, using a 2½-inch camel's-hair brush. Put on two thin coats, if necessary, in preference to one heavy coat due to make the work look brushy and rough. Then apply a coat of varnish color, which in due time is to be given a light rub over with a block of felt dipped in water and floured over with pulverized pumice stone.

Clean this surface up nicely and with a striping pencil run on some fine relief lines of a contrasting color to give a charm and distinction to the big fields of black, or blue, or green, or maroon or lake, as the case may be.

When this line work is properly dry apply for a moderately fine finish one heavy coat of clear rubbing varnish. For a still finer surface apply, in order, two coats of the rubbing varnish. Rub one or both of these coats carefully down with water and pumice flour and finish with a high-grade elastic body finishing varnish.

In the meantime fetch the chassis along, first by scouring every particle of dirt and grease from the parts.

This is a hard job and it takes patience and soap, and turpentine and crude oil, and sometimes a wash of sal soda to bring the parts out clean and decent to paint over. Then sandpaper over all, dust off and size the conditions up. Any breaks in the surface should get a touch of lead paint, and when this has dried the places needing it should be puttied with a hard drying putty.

Now apply a coat of color, then a coat of varnish color. Rub the gloss of this coat off with a clutch of upholstering moss or curled hair, apply the desired lines of contrasting color and finish with a single coat of heavy chassis varnish.

Along with this work must be taken into account mud guards, fenders, lamps, windshield brackets, radiators and other lawful accessories, all of which, as the car owner may elect, should be given their due proportion of renovating, painting and varnishing.

The automobile top is likewise in order for a process of renovation or for an application of some dressing material. Hand-buffed leather tops seldom require any treatment other than a gentle wash over with castile soap. Machine-buffed leather, when the enamel becomes worn off, will need, and should have, an application of some reliable dressing. All such dressings, however, should be put on very thin and uniform. Mohair tops brushed thoroughly with a whisk broom and then gone over with a soft brush, will come forth renewed and freshened up. Pantasote tops may receive some sort of a renovating treatment to renew them when but little worn, and if past this stage of renewal they should be given a thin, transparent dressing of an elastic nature. Pantasote curtains for railway coach use are often given a dressing of car-body finishing varnish thinned a little with turpentine.

Lamp and windshield brackets, etc., which are desired to go in some dark color corresponding to that of the car body, should, in the absence of a baking oven, be roughened with emery cloth and then given a lead priming coat. Then in due course they should be brought up with color, then one coat varnish color, rubbed, and finished with a coat of hard drying varnish.

Striping Automobile Bodies

Painters have accepted the fact that automobiles are not being, and are not likely to be, extensively striped. The plain lines in harmony with, and enriching the field color are the only ones that are being attempted in the best establishments. And, even with this narrow field of colors, the striping of an automobile is a considerable tax on the painter's ingenuity. It is difficult to find combinations of colors which give a striking or pleasing effect and still are in good taste. A few suggestions as to solving this problem are given herewith:

For medium and deep blue panels, fine lines of deep shade gold bronze, glazed with a light shade of ultramarine blue rivet attention immediately. Upon green fields of Naples yellow at one end and of primrose yellow at the other, glazed with No. 40 carmine or with English lake, the effect is enticing. Lines of chrome yellow glazed with English scarlet lake give a fine appearance.

Battleship gray, striped with 1-2-inch lines of aluminum, edged on one side with ivory black, coating the black in a fine line, reveal a splendid show of color contrast. Substitute a fine line of orange chrome for the black, or a similar line of English vermillion, and the combination produces a pleasing appearance. White striping on a gray field, lined on the edges with carmine, also imparts a distinguished air to a car.—From *The Carriage Monthly*.

Development of Automobile Fire Engines in Germany, While Split Into Electric, Gasoline and Gas-Electric Types, Agrees on Consigning Reciprocating Pumps to Scrap Heap—One of the Rotary Pumps—Subjects under Inquiry

FIRE ENGINE PUMPS—Among automobile manufacturers in Germany who build fire engines of one design or another, chosen largely in each case according to their own preferences, and who naturally wish to sell this product, and, on the other hand, the engineers of the municipal fire departments, who in some instances havé to figure on utilizing the values in wagons and steam pumps which have been in use with horses, and who in all cases wish to suit the design of the fire-fighting implements to those ideas of fire-fighting work which have been developed among themselves and their men through their experience with the old-style equipment—there is at present a lively row which finds expression at public meetings and lectures as well as in the press. The main question involved seems frequently to be this, whether the firemen can be expected to do good work from day to day when they have to learn new fire-fighting tactics as well as the handling and care of new machines. Manufacturers wish to have all those possibilities of improved tactics which they think they have incorporated in their product considered in the light of improved efficiency, and the men who bear the responsibility for the fire protection prefer to await standardization of the modernized equipment, and of the tactics to be adopted with it, before abandoning the idea that the best automobile fire equipment for the present is one which, in everything but locomotion, can be used as nearly as possible in the same manner as the old equipment was used.

Under these circumstances the technical interest centers in the fire engine pump which was a slow stroke stream pump with reciprocating pistons, but which under the new conditions is preferably operated by means of a high-speed motor—either gasoline or electric—and, if only to avoid cumbersome gear reductions, should be a high-speed pump of one type or another. The high-pressure centrifugal pumps developed for this work resemble those known in American practice, but one type has been perfected in the Berlin fire service which is different. It is known as the *Rundlaufpumpe,* or rotary pump, and was designed in the first place by a well-known inventor, W. von Pittler, now deceased. Fig. 1 shows it in its original design and Fig. 2 gives an idea of its most recent development, showing to the right, as viewed from the driving side, a schedule or cycle of the piston action, which may be followed up by comparison with the reference letters in the sectional views to the left. Owing to the indistinctness of the drawings and the cursory character of the description, only a general idea of the mechanism can be gained. The author of the information first comments upon the advantage of piston pumps, that they are adapted for raising water from a lower level where no hydrant pressure is at disposal, while centrifugal pumps must be supplied with water to work with for starting, and refers to the disadvantage that the intermittent pressure stroke of reciprocating pistons subjects the hose to a constant oscillating motion in contact with the ground, which wears the hose out prematurely and which can only be obviated in part by the installation of an air chamber acting as an equalizer. He also mentions the need of safety provisions against sudden changes in the water pressure and the wear to which the pistons are exposed, especially when sand is taken in with the water. His description of the *Rundlaufpumpe* runs substantially as follows:

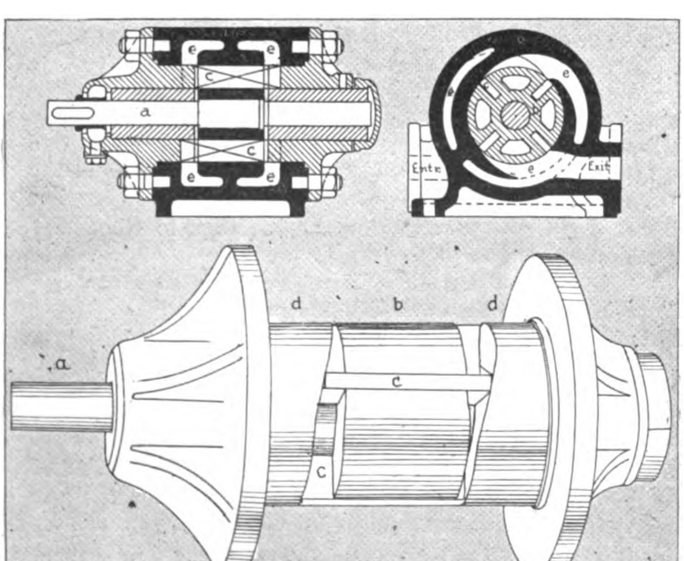

Fig. 1—Sectional views of rotary pump for fire engines as designed by V. Pittler—with side view detail of the rotary piston and adjacent parts

NEW ROTARY FIRE PUMP DESCRIBED

"It is in reality a piston pump with most of the advantages and disadvantages of this type. Its special merit lies in the possibilty of using it at very high speed. It consists of rotary elements operating in a housing, and its action depends upon alternating enlargement and reduction of the spaces formed between the rotary and the fixed parts, without use of ordinary pistons, connecting-rods or crankshaft. The effect is nevertheless that of pistons, being more or less intermittent.

"The interior of the pump consists of a through shaft (*a*) mounted in the extended bearing members noticed to the right and left in two longitudinal views under Fig. 1. This shaft carries a cylindrical body (*b*) in which four radial slots are cut out lengthwise of the body, forming pockets in each of which a rectangular hard-rubber plate is lodged, subject to axial displacement. When the shaft is turned, displacement is effected, because the ends of the plates are guided by contact with the interior end-walls (*d*) of the large bearing members through which the shaft passes, these walls being cut on an oblique curve and at all corresponding points spaced just so far apart that the distance between them is spanned by the length of each of the plates. The spaces *e* (see the sectional views under Fig. 1) are so disposed that those leading to the exit communicate at the right periods with the water which the rotation of the rubber plates brings under pressure, while those connecting with the entrance of the supply are brought under suction, and practically continuous flow from the suction channels to the pressure channels is thus effected. By having four movable plates, eight working spaces are produced and this arrangement in conjunction with high speed gives a continuity in the pressure almost equal to that effected in a centrifugal pump."

In the improved construction represented in Fig. 3 it is noticed that the movable plates are guided by means of obliquely placed ball-bearings K and that the number of the plates has been increased to six.—From *Der Motorwagen*, June 10.

Production of Quartz—The use of pure quartz is coming more and more to the front in art, industry and laboratory work. Mr. B. Daguerre tells in *Revue d'électrochimie et d'électrométallurgie* for April how it is produced. The crushed quartz mineral is placed in a graphite crucible, and the crucible is placed in an electric furnace operated with a current of 70 to 80 volts and 1,000 amperes. The current is tri-phase and acts through three converging carbon poles. The temperature is gradually raised to 1,800 degrees C., whereafter the quartz, now softened, is subjected to the action of an oxy-hydrogen torch.

Artificial Horn—Among the substances which industrial chemists are constantly trying to produce in better and better quality, with a view to the many purposes it may serve, for example, in aeroplanes and automobils, when perfected, artificial horn holds a place comparable to that of uninflammable celluloid. A new product of this nature, which is said to remain flexible and elastic at all climatic temperatures and unaffected by humidity, is obtained by mixing 50 parts of pure caseine, 50 parts of starch, 25 parts of gelatine, 0.25 parts of glycerine, 7 to 10 parts of paraffine and adding to this total quantity from 1 to 5 per cent. of alphanaphtal-sulfonic (sulfonic acid derived from alpha-naphtalene). The process is as follows: The caseine is dissolved in water containing borax. The starch is also stirred into water. In both cases the consistency should be that of a mush. The two mixtures are blended, and the gelatine, to which has been added the glycerine and the paraffine, the latter melted, is virogously stirred in with the rest. At last the sulfonic acid and, if necessary (for economy), inert matter are added. To remove the larger part of the water, the mass is rolled into sheets and, if it is required that all the water shall be removed, these are placed in alcohol. The anhydrated mass is then treated with acetate of alumina. If the substance must be obtained in bulk rather than in sheets the only available method is to unite a number of sheets under hydraulic or other strong pressure.—From *Revue de Chimie Industrielle*, June.

Tire Inflator—If sufficiently simple, inexpensive and reliable, a device which will permit the automobilist to inflate his tires by means of his motor power and without physical effort is likely to meet with popular favor. With this in view, the manner in which a device recently introduced in the French market under the name "Gonfleur Z" is mounted in the chassis as illustrated in Fig. 3. The pump has two cylinders and pistons. Stems extend upward from each piston, inside of the cylinders, of which only the lower halves are used for the working stroke, and the upper ends of the stems are yoked together by means of a crossbar capable of sliding up and down in slits in the upper portions of the cylinder walls. To the crossbar is secured a rod which may be pulled out, passing through the base piece of the pump, by means of a ring fastened to its lower end, thereby compressing the air in the cylinders and driving it out through the discharge valve and into the tire through a hose. A helical spring surrounds the rod and bears against the base. It is compressed by the working stroke and consequently takes care automatically of the suction stroke by its subsequent extension. Both the intake and discharge valves are in the base. The upper end of this pump is swiveled to one of the frame reaches L, as at T. A flexible steel band or chain B is secured at one end to the ring O, and at the other end to the other frame reach by means of a clip, D and C. This band passes under the transmission shaft A and the spring in the pump holds it nearly straight until a small roller mounted by means of a suitable lug upon shaft A, so as to act as an eccentric, is pressed down upon it by the revolution of the shaft. The roller is represented in the illustration by the dotted circles whose positions indicates how the alternate tightening and releasing of the band operates the pump. It is stated in *La Vie Automobile* of June 22, from whose pages this description is taken, that the device is capable of inflating a tire, 33 inches by 3 2-3 inches, to a pressure of 10 1-2 pounds per square centimeter (about 65 pounds per square inch) in 45 seconds, but it is not explained where power can be taken off the transmission shaft without some interference with customary design.

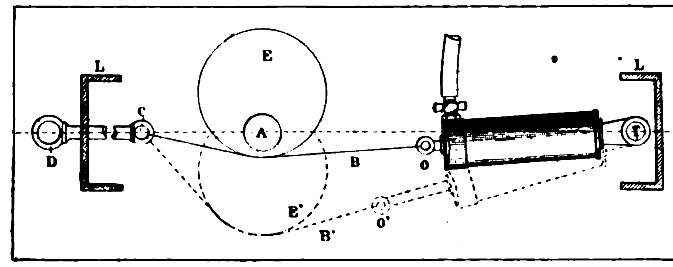

Fig. 3—Gonfleur Z type of mechanical tire pump

Subjects Under Debate—Among the subjects which are at present being investigated mathematically in the European technical press are the following: In *Génie Civil* and *Gasmotorentechnik* the developing of automobile and kindred motors operating on the Diesel motor principle, by preheating the air supply and thereby getting very high temperature at the end of a moderate compression; in *Zeitschrift des M. M. Vereins* the best type of universal joints and the construction of centrifugal speed regulators; in *Die Turbine* the design of centrifugal governors.

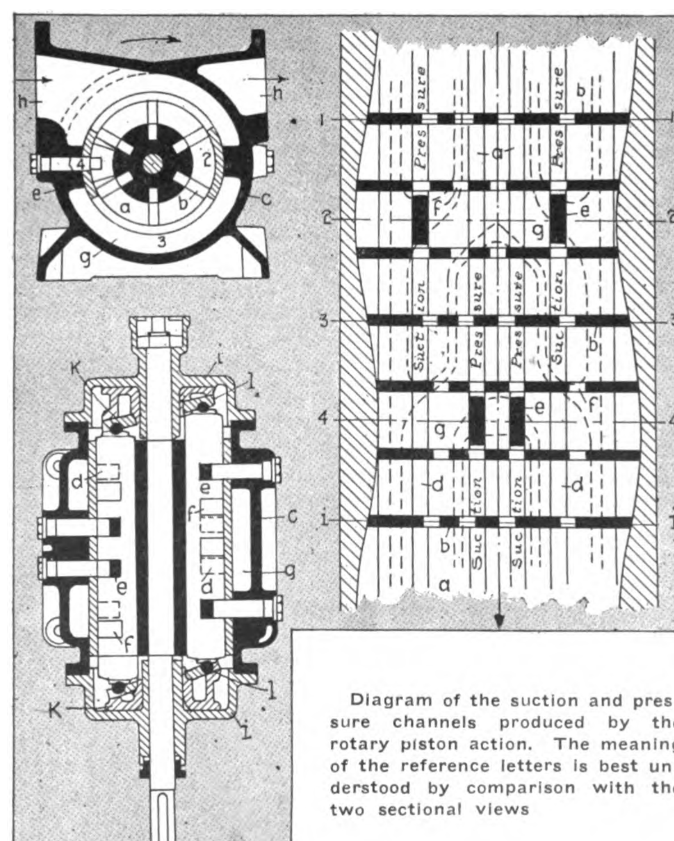

Diagram of the suction and pressure channels produced by the rotary piston action. The meaning of the reference letters is best understood by comparison with the two sectional views

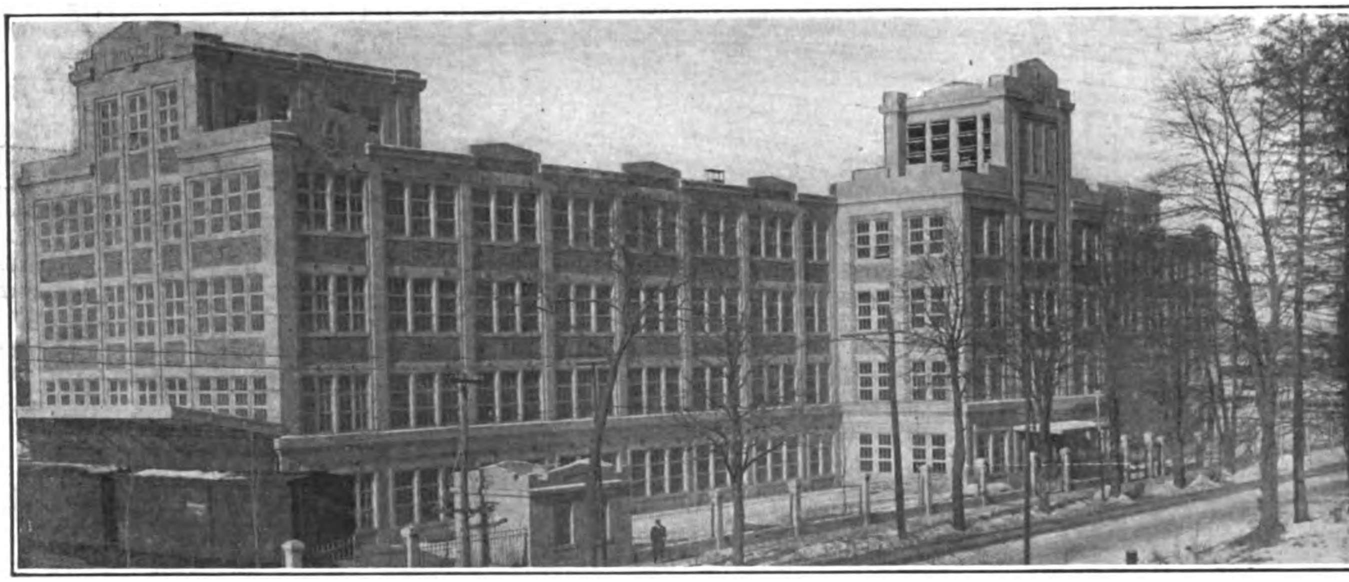

Fig. 1—Front of new Bosch factory at Springfield, Mass., showing railroad tracks coming up against one end of the building

Bosch's Modern Factory

Up-to-Date Shop Equipment and Highly Sanitary Construction Feature The New Works

Workers' Well-Being Considered a Production Factor

SITUATED in the heart of one of the greatest industrial districts of the United States and equipped with the most modern facilities in every respect, the beautiful new Bosch factory at Springfield, Mass., represents a basis upon which healthy and contented laborers may work with a high degree of efficiency. The force of the new factory comprises 1,000 men working on an available floor-space totaling more than 78,000 square feet, giving a space of 78 square feet per man in the establishment, which is illuminated and ventilated in an excellent way. These refinements constitute the most important advancement in the construction of the new plant over that of the old one.

The factory of the Bosch Magneto Company is a four-story building constructed of reinforced concrete, with a street front of 315 feet and a depth of 66 feet. Each story is 13 feet 6 inches high. The front entrance of the building is situated at the middle of the main street side and the way leads through this door to the main stairways which are four stories high and are crowned by the ventilating tower. Opposite the main stairway, on each floor, is a toilet room. From the central section, each floor extends to the end of the building where the ventilating louvers and fire escapes are located. The tower construction above each end of the building contains an intake fan and a cooling installation. The elevators are also situated at the ends of the building, and an electric dumbwaiter is provided which connects the main stockroom on the ground floor with those on the upper stories.

The most interesting features of the factory are: The shop equipment of the plant, which consists of the latest products of machine tool manufacture and includes many tools developed by the Bosch company for its own special uses; the arrangements for ventilating the building, heating the air in winter and cooling it in summer, besides keeping it free from dust, and the power plant.

Details of Ventilating System

In designing the ventilating system, the Bosch company has made a step which puts it in a position to rival the great metallurgical manufactories in Rhineland, Germany, which are famous for their sanitary construction. The fresh air is drawn in by means of two fans, on the two ends of the roof, which force it downward and through the workshops, whence it is expelled by the two large exhaust fans in the ventilating tower, Fig. 2. The quantity of air thus circulated is regulated by louvers, Fig. 4, placed between the work shops and central exhaust flue, and other louvers which are located in the walls of the stairways in the north and south ends of the building. The capacity of the exhaust fans is variable from 50,000 to 200,000 cubic feet per minute, while the intake fans can each deliver 3,000 cubic feet a minute.

In winter, only the exhaust fans are operated, so as to change the air in the shops twice each hour. This action draws in fresh air through 6-inch pipes which extend along the ceilings

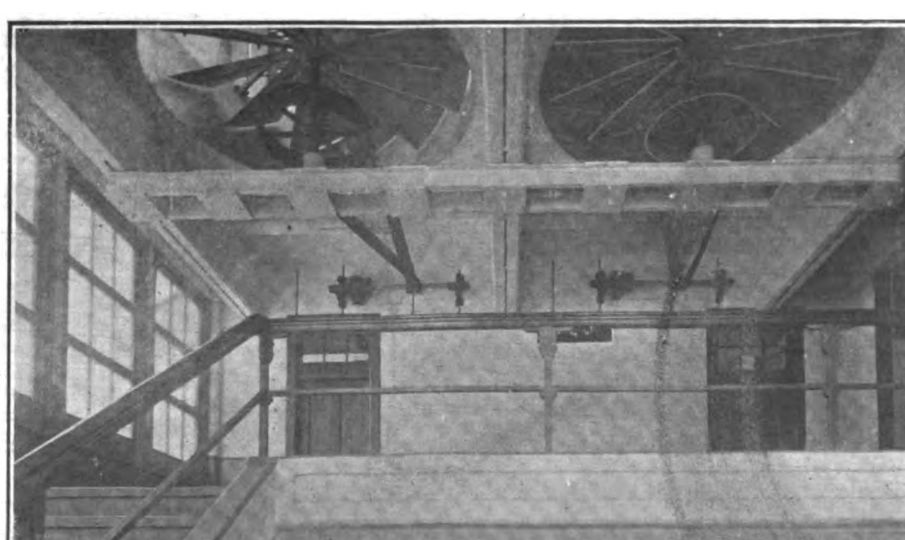

Fig. 2—Exhaust fans over stairway, expelling 50,000 to 200,000 cubic feet of air per minute

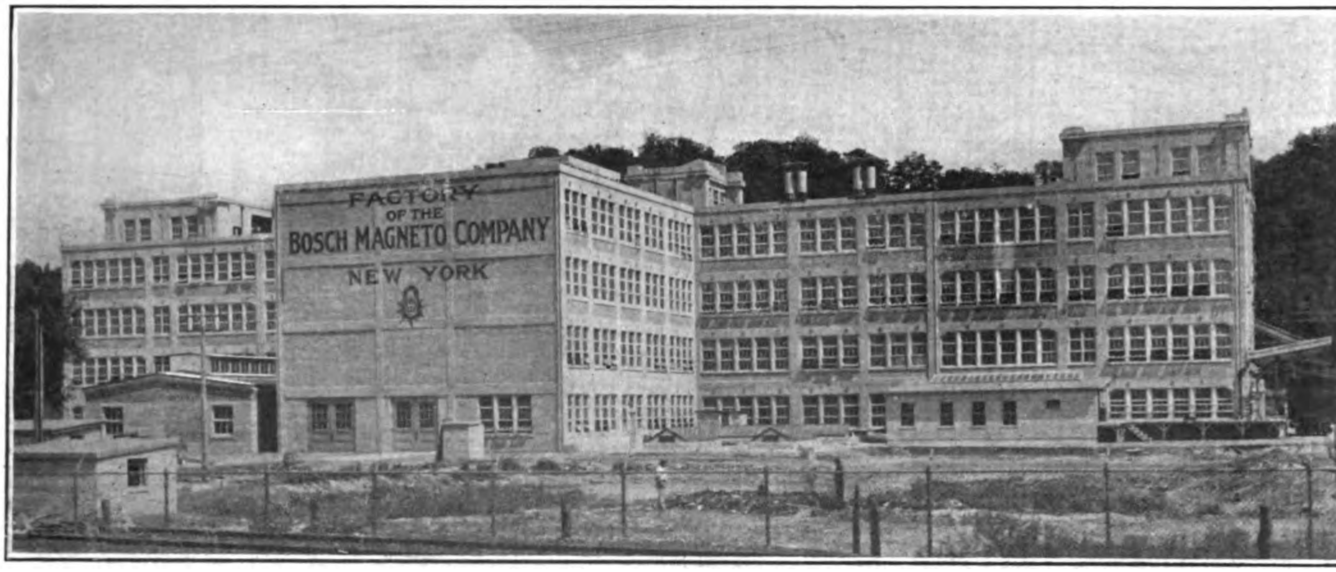

Fig. 3—Rear side of Bosch Magneto Company's new Springfield plant, with platform for unloading railroad trains at the side

and are slotted to permit the air to stream out into the shop atmosphere. This air, being cold, drops toward the floor and replaces the foul air which is exhausted through the louvers and by the fans. In the warmer season, when the windows are opened, the fresh air enters through them, and, as the temperature rises and the need for fresh air increases, the intake fans on the ends of the roof are operated.

During summer the exhaust fans are started 12 hours before sunrise, supplying fully as much fresh air as is necessary. This process also serves to cool the walls and posts thoroughly before work is started and keeps them so for some time. When the weather becomes so hot that a mere change of air does not cool the interior of the shops, the air, before passing through the louvers at the ends of the buildings, is forced through a cooling apparatus, Fig. 5. This installation consists of a series of spray nozzles keeping the chamber in which they are inclosed full of a cold mist which lowers the temperature of the air passed through it.

Heating Scheme is Adequate

An important feature of the ventilating system is that the air currents caused by it do not flow sufficiently close to the floors to raise the dust lying thereon. Incidentally, this arrangement of air streams protects the feet of the workers from cold and its effects.

The heating equipment equals the ventilating and cooling system in ingenuity. The hot air which is used to heat the shops passes through long radiator pipes at a low rate of speed, so that it radiates most of its heat. These radiators extend along the walls, but are separated by partitions from them as well as from the benches placed adjacent to them, the latter partitions being 9 feet high. This arrangement has the following effect: While the workers are protected against direct radiation from the radiator pipes, the air around the latter is heated and rises toward the ceiling, while fresh, cold air is admitted by way of the ventilator shield at the bottom of the windows. The hot air, rising, forms a wall which prevents the cold air from striking the workers and compels it to flow into the space surrounded by the partitions at both sides of the radiator pipes.

Reinforced-concrete factory is well designed and equipped. Elegant outside combined with practical and sanitary interior. Average floor-space per workman, 78 square feet. Fresh air throughout the year keeps the men efficient. The temperature in the factory is kept constant. Electric power and lighting used throughout the plant. Company manufactures many of its own special machine tools. Each magneto is tested and every operation accurately recorded.

Wash and locker rooms are located in the central section, where they form a wing attached to the rear of the structure. A similar wing is attached to the front and it is this wing that contains the main stairway and toilet rooms. The latter are also well ventilated.

Electric power and light are used throughout the factory, being produced by a 280-horsepower Diesel oil engine which is connected to a 200-kilowatt generator. The motor power is transmitted in the form of electric energy conducted from the generator to the shop by the 2-phase, 4-wire, 60-cycle, 440-volt system. The lamps used in the shop when the necessity for artificial illumination arises are 20 and 40-watt units respectively. The main driveshafts actuating the machine tools are 60 feet long. Undoubtedly, these many refinements will tend to keep up, and, if possible, improve the quality of the company's products.

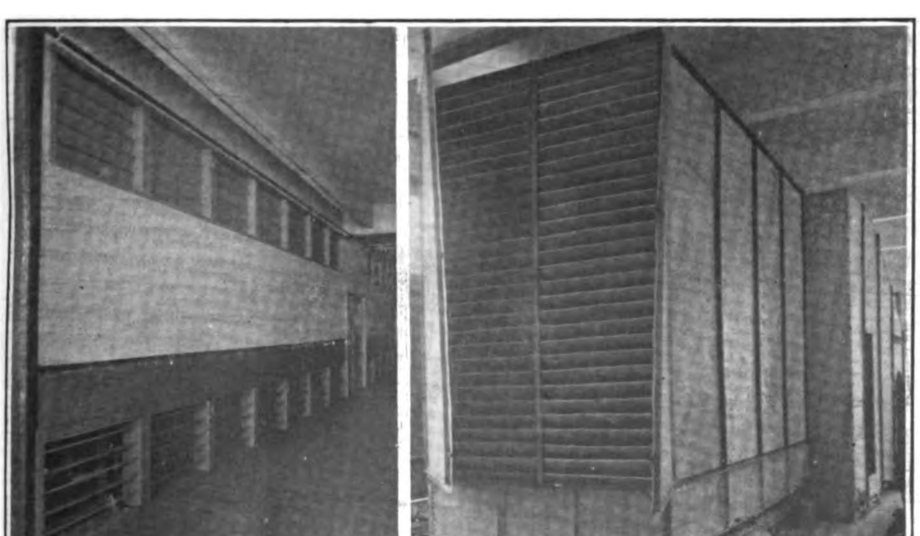

Fig. 4—Louvers regulating the quantity of air. Fig. 5—Air coolers in end towers

Putting Gears into Mesh; Tubes Blow Out Without Apparent Cause; Misfiring in One Cylinder, Motor Chokes; Smaller Radiators to Increase Efficiency; Looking for a Good Decarbonizer; Adjusting an E-M-F Clutch; Increasing Compression

Gears Do Not Mesh Correctly

EDITOR THE AUTOMOBILE:—The driving pinion in the differential set on my car is too deeply in mesh with the large differential wheel. I understand there is a method of curing this by inserting a gasket somewhere in the casing. Will THE AUTOMOBILE tell me how to do it?

Tonopah, Nev. TERRY SINCLAIR.

—You do not mention the type of car you are driving, so that there is a great possibility that you will not be able to make the repair on your car owing to a difference in construction. Taking an average method, however, the work suggested by you would be carried out as indicated in Figs. 1 and 2. The nuts shown in Fig. 1 are taken out and the whole casing containing the differential pinion bearing is removed. A gasket of the thickness that it is desired to pull out the pinion is cut and inserted between the two castings, as shown in Fig. 2. This will have the effect of drawing out the pinion, but the difficulty will not be altogether removed. The chances are that the large differential wheel will have to be moved closer against the small pinion to take up the wear on the parts owing to their wrong engagement. This can be done on some cars, but cannot be done on others. It will be easy to determine if the adjustment is possible in your particular type of car by examining the construction and method of supporting the large differential wheel. If there is an adjustment to move the gear wheel closer into mesh with the pinion it will be readily found.

Do Others Have This Trouble?

Editor THE AUTOMOBILE:—I wish to state my case and find out if there are any others in the same predicament as myself. My tubes, which are of a very well-known make with a good reputation, burst on the rim side and this nearly always happens when the car is standing idle. I have had this happen several times in one day. It started after I had driven my car its first 700 miles, the car and tires being practically new. I have had this trouble ever since. Patches will not cure it, as it rips open under the edge of any patch. I keep the tire fully inflated according to inflation table. The tires are of the clincher type and I have sent to the local agent, who renewed the sample casings I sent, but could not offer any clue to the cause of the trouble. I would like to know if any others are troubled in the same manner.

Lyon Station, Pa. MILTON SAUERMILCH.

—It is impossible to say without being on the ground. Other readers of THE AUTOMOBILE who see this may have had the same trouble and know what causes it. There is a possibility of the security bolts pinching the tubes when you put them into the tire nut, though it does not seem possible that this should happen so frequently. Try taking greater care when placing them in the casing.

Pinching very commonly results from the beads of the casing squeezing the inner tube between them, causing a blowout. Insufficient pressure is the principal cause for this.

One Cylinder Misfires Badly

Editor THE AUTOMOBILE:—Can THE AUTOMOBILE tell me what is the trouble with my car? On a recent trip, soon after starting out, one cylinder began to miss and I could not entirely overcome the difficulty even after changing the spark-plugs, looking over all the wiring and connections, readjusting the vibrator and, in short, doing everything I could think of. It would run along smoothly for a time and then the trouble would develop. The car has been driven only 1,100 miles and has had very careful handling. The compression in each cylinder is the same. The car is a model T Ford.

Portage, Wis. L. E. GRANT.

—Look for a leak in the intake pipe leading to the bad cylinder. There is a chance that the mixture is weakened by a leakage of air into this cylinder which causes it to misfire. Trembler fatigue is sometimes responsible for an elusive misfire. This is rare but should the trouble be traced to this the cure is a new trembler. Clean the contact points in the timer with a few drops of gasoline and be sure that the spark-plug in the missing cylinder is in good condition, both as regards its insulation and the gap at the electrodes, which should be only wide enough to admit the edge of a doubled business card. A mistake which is made occasionally by people who have taken the valves off the motor is putting the inlet spring where the exhaust valve spring should be. After becoming warm, the action of the exhaust valve is

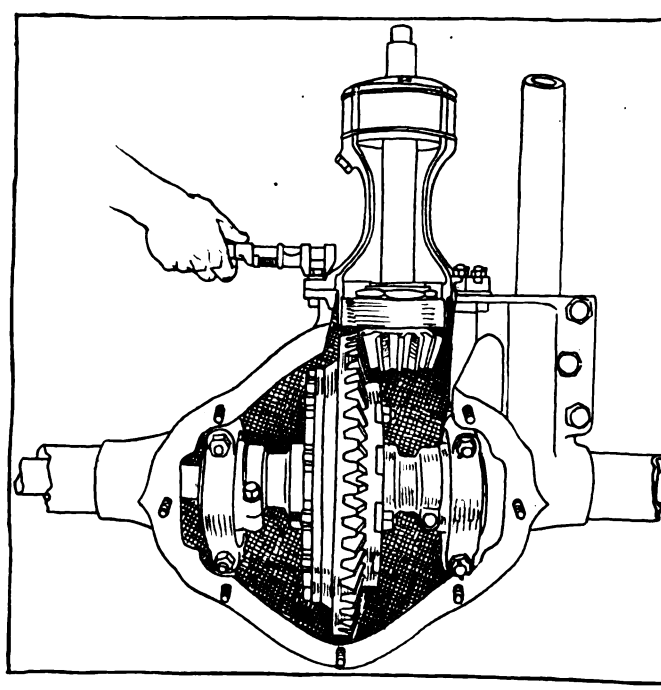

Fig. 1—Showing bolts which have to be removed in adjusting gear mesh

slower, owing to the weaker spring, causing a miss in this cylinder. On the Ford cars a very light trembler adjustment is necessary. If you have not tried a still lighter adjustment it would be advisable to try this. In case the valves have been ground, in spite of the short distance that the car has been run, there is the possibility that the stem of the valve is too long. It is a fact with these cars that the stems wear very much slower than do the valve seats so that a change of adjustment is necessary after a time or else the valves will open too early.

Chokes After a Fast, Stiff Pull

Editor THE AUTOMOBILE:—I have a 1911 Velie which is giving me a lot of trouble by choking up and skipping after a stiff pull of say 1-2 mile or more at the rate of from 25 to 35 miles an hour. I have tried all adjustments on both the B4, 1 1-4 and B5, 1 1-2-inch Stromberg carbureters, but without helping the situation any. The valves are in good condition as are also the piston rings. Can THE AUTOMOBILE suggest a possible cause for this trouble?

Easton, Me. H. R. DELAITE.

—If you are not bothered by air leaks of any kind, the whole trouble lies in an improper carbureter adjustment. It is entirely a matter of starting at the bottom and working through the adjustment rather than simply trying different adjustments after the motor starts to develop trouble. The correct way to adjust the carbureter is as follows:

After you have the gasoline turned on, first notice if the level is correct. It should be 15-16 inch above the rim on the bottom of the glass. If it is not, the level may be adjusted by turning the gasoline level adjusting nut M, Fig. 3. The level in the float chamber does not change as the nut M is turned but only after the motor has been started and stopped. If the level is not correct, it is a matter of turning the nut, starting the motor and then seeing if the level is correct when the motor is stopped. If not, the nut will have to be turned again and the motor started and stopped until the level is finally correct. Next, see if the air valve is seated correctly. It should rest lightly against its seating and this condition can be determined by tapping on the nut above the high-speed spring. If it does not seat, turn up the adjusting nut K, or, if too tight, turn the nut K down. Prime the carbureter until the float chamber is full. It will be noticed that some of the gasoline drops into the adjustable air

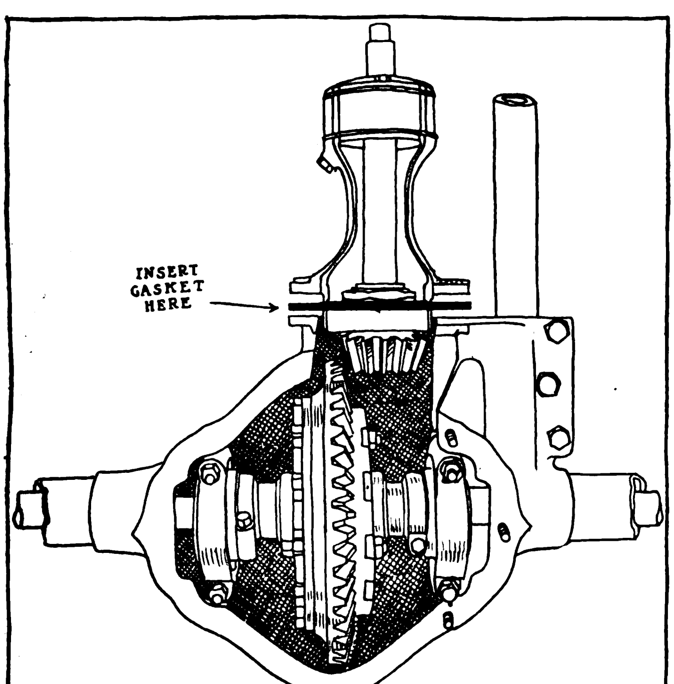

Fig. 2—Where the gasket should be inserted to bring gears into mesh

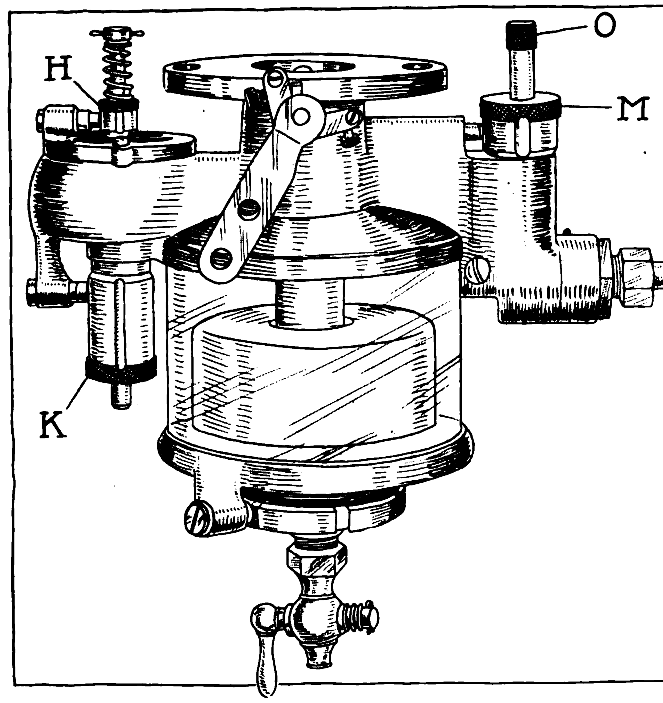

Fig. 3—Illustrating the adjusting points on B-type Stromberg carbureter

cup on the bottom of the carbureter. Turn this cup up as far as it will go and then turn it back two turns. On the average motor this will admit the proper amount of air, which regulates the gasoline supply. Next start the motor and turn the low-speed adjusting nut K with both the throttle closed and the spark retarded until the proper adjustment is secured. If the mixture is too rare, the engine backfires. In this case, turn up the nut K until the motor runs smoothly. It is wise to allow the motor to backfire at first, starting with this condition and screwing up on the adjustment until it runs smoothly. Next advance the spark and open the throttle gradually until it is wide open and if the motor backfires turn up the high-speed adjusting nut H one notch at a time until the motor runs without backfiring. Remember that the valve above the high-speed adjusting nut simply controls the air valve on open throttle or high speed. It should not be in contact with the nut above it when the motor is at rest. The seating of the auxiliary air valve is entirely controlled by the low-speed spring and there should be a space between the nut and the high-speed spring of not over 1-8 inch. It may be that, in adjusting the high-speed nut, in order to stop backfiring at high speeds, you will have to turn up the low-speed nut one or two notches. Do not do this unless you have to. After this be sure to see if the motor runs smoothly on a closed throttle.

The motor uses just enough gasoline to keep it going on low speed, and, as it increases in speed, it takes the necessary supply automatically. The motor suction draws air through the fixed air opening between the adjustable air cup and the bottom of the gasoline chamber, the air passing up through the mixing chamber through the spray nozzle, after which it is joined by the air entering through the auxiliary air valve, producing the required mixture. The more air that comes in through the adjustable air cup and the less through the valve, the richer will be the mixture, and *vice versa* Therefore, the low-speed spring should not be adjusted too tight. To change the spray nozzle, take off the draincock, whereupon the spray nozzle may be removed by means of a screw-driver.

Radiators Could Be Smaller

Editor THE AUTOMOBILE:—In reference to the communication by P. G. Tismer, I think that, in the main, he is wrong. The writer seems to ask a lot of questions but does not pause to

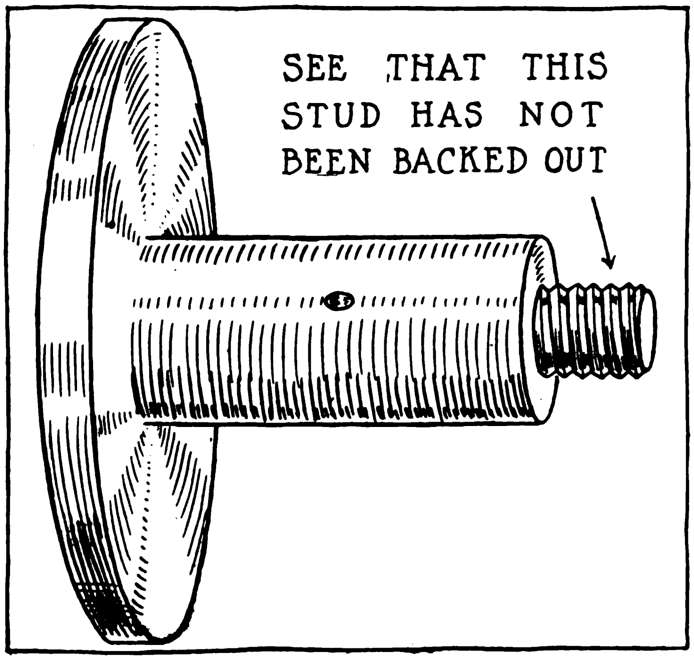

Fig. 4—Stud in flywheel end of E-M-F crankshaft which should be kept tight

take the obvious answer to many of them from daily practice in the automobile field. The Franklin car, for instance, is operated without waterjackets and operates very well indeed, but, nevertheless, it is a fact that the engineers of this concern were compelled to use their utmost resourcefulness in designing the excellent cooling system which they have today. The greatest cooling area which it is possible to submit to the cooling currents of air has been given the cylinders. The motor runs at a higher temperature than the water-cooled motor, but certainly does not reach the high temperature at which Mr. Tismer claims that his motor operates. I would like to know the make of the motor and horsepower. That lubricating difficulties have not developed is remarkable, considering the circumstances under which the motor is compelled to act.

What I do think, however, is that the modern gas engine could be made to operate at a slightly higher temperature and thus raise the thermal efficiency to some degree on account of less loss of heat to the cooling water. I would recommend that the merits of greatly reduced radiator area be investigated as I think that this is a solution of the problem of raising the thermal efficiency of the average touring car.

New York City. READER.

—A reduction of the heat thrown away in cooling the motor would be a very long step towards increasing the thermal efficiency of the motor, but practical difficulties in the way of steam intervene when the temperature of the water goes above 212 degrees Fahrenheit. The boiling radiator is a barrier in the way of reducing cooling area.

Car Has No Clutch Adjustment

Editor THE AUTOMOBILE:—I have an E.M.F. 30, 1910. I would like to know how to adjust the clutch. I have examined it and can find no way to adjust it, although it is slipping continually. How do you do it?

Parkersburg, W. Va. READER.

—There is no way of adjusting the clutch on the car of which you write. There are five things which could cause your clutch to slip and each of them is readily curable. As you offer no clue to which of these five your trouble is due, it would be best to take these up one by one in the order of their probability:

(1) Rivet projecting through leather. The rivets in the leather facing of the cone are supposed to be countersunk. This is essential as otherwise the clutch will not hold. When the metal sticks out beyond the leather there is a metal-to-metal contact which will not hold at all. It often happens that the rivet is only slightly countersunk when the car leaves the factory and after a time the leather wears away, leaving the rivet flush with the surface. The cure is to punch out the offending rivet, counterbore the leather for a short distance and put in a new copper rivet, being careful to get the head well below the surface after the rivet is flattened out.

(2) Leather glazed and somewhat hard. The best cure is to renew the leather. To do this, take the old leather as a pattern to cut out a new piece, or, better still, send to the factory for a new clutch leather. It will cost $2.00, but it will be correctly treated for the clutch facing. When putting it on be careful to counterbore the leather for each rivet. That is, make the hole in the leather first the same size as the hole in the metal against which the leather fits. Then, for a distance of 1-2 the thickness of the leather drill a hole with a slightly greater diameter with the same center as the first hole. This will give a seating in the leather for the rivet. Be careful in fitting the leather to stretch it on tightly or it will wrinkle and the clutch will seize. The probability is that, if the trouble has been the projecting rivet, as taken up under (1), the leather has become somewhat glazed, owing to the frequent slipping. The cure for a slight glaze is to thoroughly saturate the leather with neat's-foot oil. It must stand at least 24 hours after the application of the oil or the leather will not have time to take it all up. The clutch leather must be soft or the action of the clutch can never be right. It would be advisable, as long as you are working on the clutch, to give it this treatment of neat's-foot oil, no matter what the trouble may be.

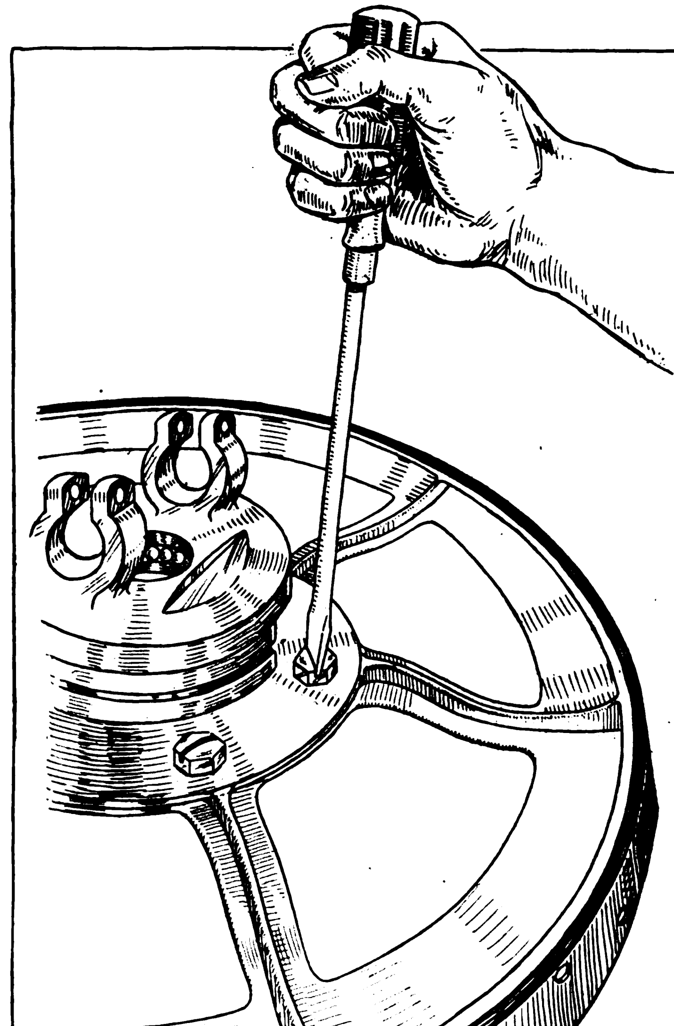

Fig. 5—Removing screw to get at the spring of the clutch used on E-M-F

(3) Leather worn away. In a case of this kind the only possible cure is to apply a new leather facing which may be accomplished under the directions given in (2).

(4) Crankshaft stud bolt backed out. In the flywheel end of the crankshaft is a stud, Fig. 2. The purpose of this stud is to hold the clutch in its correct relative position When the stud backs out a short distance, as often happens after the car has been in use for some time, it does not permit the clutch to fully engage, and, as a result, it slips. The remedy is to turn this stud up as far as it will go. When the clutch is removed the stud should be tried and, if loose, tightened at once.

(5) The last possibility is that the clutch spring is broken. This is extremely unlikely, for you would have found it out before now. Should this be the case, however, the cure is to renew the spring. The new spring will cost very little and it is easily put in place. The bolts shown in Fig. 5 will have to be removed to get at the spring. In replacing these bolts tighten them alternately. That is, take up a turn on every other bolt going around the flange so that the strain falls equally on all of them.

Looking for a Decarbonizer

Editor THE AUTOMOBILE:—I often see dry powder carbon removers advertised. The powder is put into the cylinder after a run and is said to clean out carbon well. Do you know anything about them? I have been in the habit of using a little kerosene oil. The only objection to this material is that you have to clean out the crankcase after it is used. If one could find a really good preparation in powder form it would certainly be a boon. I do not care to try experiments and greatly prefer to learn from the other fellow's experience. I have a 1912 Overland touring car and after more than 1,500 miles on our none-too-good roads, am delighted with it. No carbon has formed as yet in the cylinders.

Bridgetown, N. S. W. A. WARREN.

—The method you use in injecting a little kerosene into each cylinder is very good and should prove very satisfactory. You will not have to renew the oil supply if you do not put more than a tablespoonful of oil into each petcock while the motor is hot. The kerosene will vaporize and dissolve the carbon. There are all kinds of good carbon removers on the market, some giving better results than kerosene because they are stronger solvents. Without an exception they cost more, however, and you should not need them except occasionally if you use the kerosene after each trip. Carbon deposits will never trouble you much, anyway, if you do not use an oversupply of oil and take pains in selecting the oil you buy. Never stint the price on this important article as poor oil will mean all sorts of trouble in the end, not only from carbon but from other evils of bad lubrication.

To Reduce Compression Space

Editor THE AUTOMOBILE:—I wish to reduce the compression space in my Ford 20-horsepower car. I have been thinking of putting aluminum plates inside the cylinder heads, bolting them on in good shape, the plates being cast to the shape of the cylinder heads. I would like THE AUTOMOBILE to tell me how much space to have between the plates and the piston heads.

Mellen, Wis. JOHN LUNDQUST.

—If you are fortunate, this change will cost you only about $2.00. Look at your cylinder at the point where the water pipe to the radiator leaves it and see if there is a small X on the outside of the casting. If so, you have one of the low-compression heads which can be exchanged for a high-compression head at a cost of $2.00 if you take the matter up directly with the Ford people. Aluminum melts at 1,157 degrees Fahrenheit and would not be suitable for use within the cylinder as the temperature at the time of combustion runs considerably above this and the waterjackets may not be able to take care of the extra plates fast enough to prevent trouble Soft gray iron would be more suitable if you intend to put anything

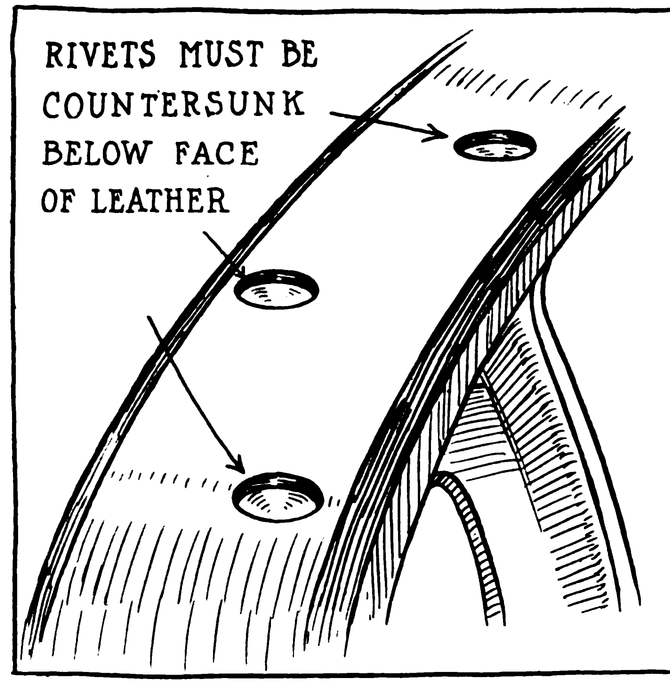

Fig. 6—The copper rivets must always be below the surface of the leather

in the cylinder, although it is not advisable. The amount of space left above the piston would depend on the extent to which you wished to increase the compression. For racing purposes, this could be as much as 90 pounds. The way to determine the volume of extra metal to put into the combustion space is as follows: Measure the compression that you have now in the cylinder. Call this P. Measure the present volume of the compression space as nearly as you can by putting the piston on upper dead center and filling the space above with heavy oil and then measuring this. The way to proceed with this is as follows: Take a gallon, exact measure, of heavy cylinder oil and weigh it. Then pour in enough oil to fill the entire compression space when the piston is on the top dead center of the firing stroke Now weigh the oil that remains. The former weight of the oil divided by 231 will equal the present weight of the oil divided by the cubic inches remaining in the can. 231 less the latter quantity will be the volume of the compression space, V. The volume of metal to be added to the cylinder to increase the compression D pounds would be

$$\frac{DV}{P}$$

A better way of reducing the compression space would be to plane off the lower face of the cylinder where it again fits against the crankcase casting and also to plane off the face of the cylinder head, making closer fits at both these points and permitting the piston to travel further up into the cylinder, thus increasing the compression. It is greatly to be doubted if you will find a perceptible gain in the running qualities of your car after you have changed the compression, except, perhaps, the engine will start more easily.

Letters Should Be Signed

[THE AUTOMOBILE is holding a few queries and communications which have been received unsigned. If a correspondent does not wish his name published it is merely necessary to state this fact in the letter and a nom de plume will be substituted. As an evidence of good faith, however, it is required that all communications be signed. Those which have been received up to date will be held until the identity of the sender is known. All communications will be answered strictly in the order in which they are received.—EDITOR.]

Papers Read at the S. A. E. Convention

Shipboard Meeting Brought Forth Several Valuable Contributions To Automobile Engineering Science

Much of the Material Brought to Light Had to Do With the Commercial Phase of the Industry, and the Discussion Which Followed the Reading of Each Paper Was Particularly Interesting In That It Developed Many Additional Points of Value

Motor Sizes and Drive Ratios for Commercial Vehicles

By E. P. Batzell, S.A.E.

Showing Necessity of Sufficient Power in Motors Designed for Every-Day Truck and Delivery Work—Importance of Proper Gear

ONE of the milestones of the midsummer session of the S. A. E. on the Great Lakes, between Detroit and Mackinac Island and return, was the attention devoted to the most suitable designs of motor for different size trucks, as well as the work in standardizing truck wheel sizes and tires. The two moving convention spirits in this work were E. P. Batzell, who exploited the matter of motor sizes, and W. P. Kennedy, who dealt with standardizing wheels sizes and tires. The discussions on both subjects were exhaustive, particularly that on motor sizes, which brought responses from nearly every representative of truck concerns at the session. The general consensus regarding motors for trucks was that they are too large, consume too much gasoline, are too heavy and out of all proportion to the transmission parts. Every one concluded that it was an error to try to adapt a pleasure car motor to truck uses because the services are so different. In a pleasure car the motor works but a very small proportion of the time, whereas in trucks it is working steadily for 10 hours a day under load. This steady service calls for large crankshafts, large crankshaft and connecting-rod bearing surfaces, large crankcase parts and slower motor speeds. There was a general consensus of opinion in favor of lower piston speeds and the design of motors, to give high efficiencies at medium crankshaft speeds.

The question of permissible or advisable speeds in miles per hour for trucks came up for sharp discussion. Some held for 8 to 9 miles per hour for a 5-ton truck, as compared with 12 or 13 miles per hour by others.

Variations in Truck Practices

Mr. Batzell in his paper, "Motor Sizes and Drive Ratios for Commercial Vehicles," showed the startling variations in truck motor practices, drew attention to the errors of motorizing a truck with a power plant taken from a pleasure car and the expense of over-motoring. Space permits of publishing here only leading extracts from Mr. Batzell's paper, together with the views expressed in discussion by the members. The complete paper may be published later. The following are extracts, setting forth the general points of the paper, but leaving out all of the mathematical calculations required in demonstrating the necessary construction in a motor truck, as well as the numerous charts illustrating the results of various tests:

The question of the selection of motor sizes for commercial vehicles has not been discussed much or often. It may be discussed as to several different basic conditions. In this paper it will be taken up principally from the standpoint of general economy, this being presumably most vital in successful commercial car service. Under general economy there are not only economy in consumption of fuel and oil, but also economy in the initial cost of the motor and its whole upkeep expense. At first the consumption of fuel only will be investigated, as to its variation according to different motor sizes for the same work. By assuming equal working conditions whenever comparison is being drawn, one need not keep track of the total fuel consumption in every case, but of merely the consumption per developed unit of work.

The abnormally great variation of present truck motor sizes is obvious. Taking the motor sizes of trucks of equal hauling capacity, as shown this year at the principal automobile shows, one will find in the case of 1-ton trucks the piston displacement varying from 144 cubic inches to 350 cubic inches, and in the case of 3-ton trucks from 230 cubic inches to 570 cubic inches. Figuring the above volumes at an equal piston speed of about 800 feet per minute, the respective variations become: total piston displacement per minute of 1-ton truck motors from 100 cubic feet to 178 cubic feet, and of 3-ton truck motors, from 135 cubic feet to 264 cubic feet. Taking into consideration the difference of the weight of the vehicles proper, together with their rated load, the piston displacement per pound of this weight in the case of the 1-ton truck varies from 40 cubic inches up to 61 cubic inches, and in the case of the 3-ton truck from 21 cubic inches to 38 cubic inches per minute.

Efficiency Depends on Design

When a truck does a definite amount of work by using some 50 per cent. less volume of piston-swept cylinder space than a similar truck of another make, one motor may be developing less power per cubic inch of piston displacement than the other, or the power losses in the mechanism of one truck may be much greater than in the other. The efficiency of an automobile driving mechanism differs greatly according to the general constructive features incorporated. However, in many cases of well-built trucks the transmission of the motor power to the driving-wheels occurs under approximately equal conditions. Consequently the motors of different size, but developing the same power, are acting under entirely different conditions in regard to transforming their gas explosions into outside work.

The power developed per unit of piston displacement depends on the charge taken into the cylinder, the compression ratio, the heat losses, the carburation and gas mixture consistency, ignition, timing and a few other things. The present discussion refers only to common 4-cycle engines. The compression space in truck motors is frequently 28 to 30 per cent. of the total cylinder volume, as against 20 to 23 per cent., and sometimes less in pleasure cars. Inasmuch as high compression motors develop at medium speed relatively more power than low compression motors, the difference in truck motor sizes can be explained in part by the difference of compression used. A variation of motor size within 5 to 10 per cent. of the piston displacement can be thus explained.

In certain cases it happens that a manufacturer uses a pleasure car type motor for trucks, either because the same motor is used also in his pleasure cars or because he is able to secure the motors on otherwise profitable terms. Putting pleasure car motors into trucks explains further why truck motor sizes vary so much. A comparatively small pleasure car engine is apt to have enough power for commercial car purposes in certain cases where otherwise a larger motor would be advisable; the high compression of the former assisting somewhat in power development. Such an engine, if kept working at comparatively slow piston speed, may hold out well and also prove sufficiently economical in fuel consumption, because it has a higher thermal efficiency than the low compression motor, providing it has a good volumetric efficiency. On the other hand, when an oversized pleasure car engine is used for a truck of comparatively small carrying capacity, the engine will have an abundance of power for even any extreme case of requirement during service, but most of the time it will be developing only a small part of its power capacity. Consequently this engine will work with very little cylinder filling by fresh charge, with small throttle opening, and the thermal efficiency will be low, as well as the mechanical efficiency, because the amount of power lost in the mechanism of the engine proper will be large as compared with the amount of power generated by the motor. Moreover, the initial cost of oversize motors is considerable, and they weigh more and take more space than motors of rational size and power for a given purpose.

Power Plant Should Be Adequate

It might be said that a larger engine gives better assurance against interruptions in service apt to occur from lack of power. This may be true in cases where severe requirements and hard work with large power consumption are anticipated. However, instances of abnormal use of power are not encountered very often, and it should not be considered good policy to fit all trucks of a certain carrying capacity with a power plant large enough to take it at high speed over hard roads on a steep grade. The proper way is to furnish trucks of a certain carrying capacity with power plants of different size to suit most economically the conditions to be encountered in the prospective service. If the selection of power plants is correctly made marked results in economy of service operation can be shown.

It has been already stated that relatively high compression raises the thermal efficiency. On the other hand, it means higher pressure throughout the moving parts of the engine, and consequently the losses due to friction in them become greater also. Moreover, at slow speed the heat losses through the cylinder wall, especially through that surrounding the combustion chamber, are greater with high engine compression than with low, notwithstanding the larger area exposed to cooling in the latter. In some instances these losses may more than offset the gain in the thermal elapsing of the engine cycle. At any rate, they limit the compression ratio, which is economical for commercial car purposes.

When considering the high compression employed in pleasure car motors it must be remembered that they are high-speed motors working most of the time with comparatively low volumetric efficiency. It seldom happens in pleasure car practice that the motor is run at slow speed with the throttle wide open, and when it does happen the duration of such running is generally short. The high-compression motor has sufficient time to recover from this severe working condition which imposes great requirements upon all its parts, and especially upon the cooling system. Pleasure cars, being driven at slow speed mostly with small throttle opening, or with larger throttle opening at higher speed, take only a small quantity of fresh charge into their cylinders per suction stroke, and consequently, notwithstanding the theoretical compression ratio, the compression pressures are comparatively low. This is because the absolute pressure at the end of the intake stroke is lower in a cylinder working with smaller volumetric filling. The commercial cars generally make use of slow-speed engines, which have a more complete cylinder filling by fresh gases, other things being equal. Therefore the high compression ratios, if used in them, would disclose much sooner the bad effects upon the engine parts from the higher pressures of the working cycle, resulting from the more complete volumetric cylinder filling, than if the pressure had been preserved at the average pleasure car values. Thus is established the advisability of a fairly small compression ratio in commercial car motors. Even if this slightly reduces the thermal efficiency, the prolonged life of the motor ought to offset it. Contrary to the nature of pleasure car work the commercial cars are run much more frequently under conditions requiring a fairly constant and large amount of their motor power for a long time. One cannot rely on relieving the motors from signs of overwork during easy runs which alternate with the periods of harder work.

Maximum Torque at Slow Speed

Torque—The volume of cylinder filling by fresh charge during 1-cycle period is closely interconnected with the engine's pressure diagram, it being supposed that the engine has reached the stationary state of its thermal balance, viz., its cycle heat exchange. The cylinder filling is likewise interconnected with the developed motor power and torque, the latter being equal to the mean diagram pressure, times the piston area, times the crank radius, times the mechanical efficiency of the motor. In most well-proportioned automobile motors the maximum torque is developed at very slow speed, the slowest at which the motor will run under full load. However, many features of motor construction, parts alignment, carbureter action, timing, etc., affect this in one way or another so that the point of maximum torque cannot actually be foreseen even approximately. As mentioned, the heat losses occurring during an engine cycle are considerably higher at slow speed, which reduces accordingly the thermal efficiency and the rate of power production per contained amount of fresh charge in the cylinder. If no heat were lost through the cylinder walls, the greatest pressure diagram area of the motor working cycle would be reached at the moment of greatest cylinder filling, perfect carburetion of gas mixture being assumed. But on account of the existing loss of heat this greatest area is located at certain higher revolutions per minute when the length of time per motor stroke, during which the cylinders are exposed to the charge, is reduced. This time should be reduced enough so that notwithstanding a less complete cylinder filling at the higher speed, the most favorable conditions of generating power from the explosive charge are had. These conditions are seldom obtained in practice. They require that the motor deliver considerable work at a low speed, when the latter does not influence appreciably the volumetric cylinder filling through choking in the intake valves and passages. In fact, the slowest obtainable motor speed under load with full-throttle opening would lie most often above the revolutions per minute at which the rate of reducing the heat losses equalizes the rate of volumetric filling decrease with rising speed.

When considering the cylinder filling purely theoretically, as the result of filling a compartment under influence of a pressure difference created by the suction action of a piston, the greatest volumetric filling corresponds to the lowest recorded motor speed. However, if a true reproduction of the motor performance is desired, certain practical points which might alter the former theoretical result must be introduced. One must separate the meaning of actual volumetric cylinder filling, which refers only to volume, from the best cylinder filling, as mentioned in this article. The second meaning is intended to denote not only the volume of gas freshly taken into a cylinder during the inlet period, but also this volume adjusted according to the state of the air and gasoline mixture in regard to the capacity of power development by this latter. Although the greatest measurable volume of air and gas would be drawn into a cylinder at the lowest speed, the conditions of the air, of the gasoline, of the carbureter adjustments, etc., may be such that the most effective mixture consistency, considered from the point of power development per unit of volume, would appear at a somewhat higher revolution per minute. Consequently the point of the best cylinder filling would lie somewhere between the lowest obtainable motor revolution per minute and the revolution per minute at which the best mixture consistency is reached. Its location marks the point at which the decrease of volumetric filling is counterbalanced by the improvement occurring in the mixture quality. Moreover, the condition of some of the motor parts might exert an influence on the moment of best cylinder filling, deduced as the result of apparent power generating, when, for instance, leaky places around the valves, pistons, etc., permit the escape of a larger amount of gases at slower speed.

Changes in the Gas Velocity

The actual volumetric cylinder filling is represented by a curve which has a maximum at the slowest motor speed, gradually decreased up to certain much higher revolution per minute, and then begins to rise slowly once more. This last rising part of the curve can be explained partly by the inertia of the gases acquired during the suction stroke, the inertia increasing rapidly with the revolutions per minute. After a certain speed is reached the gas velocity is so high that a larger amount enters the cylinder during the latter part of the suction stroke; then the decrease is effected through greater throttling of the gas flow due to higher velocity. This would become particularly noticeable at high revolution per minute in motors with late inlet closing, and also in motors with earlier inlet closing, when their inlet valves are small and choke the passing gases considerably. The curve mentioned can also represent the elapsing of the best cylinder filling with the motor speed; in other words, this latter filling coincides with the volumetric one, when assuming that the carbureter delivers a mixture of best consistency from the lowest motor speed on, and that the motor itself is in good condition throughout.

Within practical limits the coefficient of friction generally decreases as the motor runs faster. Another item to be included in the mechanical motor losses is represented by the power required for driving the air fan, the oil and water pumps, the magneto, etc., which also increases with the motor speed. Whether the resulting percentage of total mechanical losses in a motor will increase, remain constant or decrease with the gain of speed depends on the relation between the above-named kinds of power losses. Were it possible for a motor to retain a constant pressure diagram area through a range of speeds, the respective torque curve would gradually drop or rise according to whether the mechanical efficiency dropped or rose. However, the pressure diagram area will almost always be reduced at higher speed, and therefore the point of maximum torque lies at higher revolutions per minute than the area maximum for the case when the percentage of mechanical losses is decreasing at rising speed; the exact location of the point would be where the decrease of diagram area is equaled and compensated by the simultaneous decrease of mechanical losses. On the contrary, should the percentage of the latter represent a value increasing with the motor speed, the maximum torque will be located at the point of greatest recorded diagram area, on the assumption that this corresponds to the lowest speed of which the motor is capable under full load, and that the functioning takes place properly. In the case of an irregularly acting motor, showing from the beginning a rising value of the pressure diagram area, the maximum of the developed torque will be located at lower revolution per minute than that of the area, and also at the point where the increase of one item is compensated by the decrease of the other.

At present many commercial cars are equipped with too powerful motors and with only two forward speeds. Reconsidering the statements of this paper for a case of a two-speed transmission one would find that here the motor must be more powerful than where a greater number of speeds are used because it has to have ample torque when the tractive resistance does not warrant the use of the low gear, but is greater than the average encountered. The single reduction in the drive necessarily being low enough to overcome the greatest expected resistance, and present practice seldom making it more than 30 to 1, or more than twice higher than the lowest ratio figured in the above example, in equally extreme conditions the two-speed transmission requires more than twice the developed motor torque of the four-speed one with a proper lowest ratio, determined in accordance with the description given above. Such an oversize motor would actually perform the service required, but without any consideration of desired economy. In many instances the motion of the vehicle would occur with a tractive resistance by far smaller than that which the motor can overcome with full-open throttle; consequently, the frequency and duration of its runs with partially closed throttle increase. An observation of such trucks in actual service conditions would make this plain, because there is hardly a chance of seeing them running with wide-open throttle, which indicates that the motor is not loaded to economical capacity. On the other hand, the road resistance might become too great to be taken care of by the direct-drive ratio of the car, with open throttle, necessitating the use of the low gear. This ratio might be so low that a very small throttle opening would suffice to develop the required power. Moreover, the speed of the vehicle would be reduced correspondingly, bringing the vehicle down to 4 to 5 miles per hour, or even less, whereas a much greater promptness could be maintained with the intermediate ratio of a three or four-speed transmission. The two-speed transmission involves extra expense, such as for fuel consumed, time wasted by slowing down below the speed corresponding to the actual requirements of the road conditions, large motor with interconnected inconveniences, etc., all for the sake of gaining a trifling simplification in the transmission construction. It is easily seen that the two-speed transmission is not satisfactory in commercial work.

Some Economical Requirements

It is to be noticed that the foregoing discussion deals with the question of the most economical motor size without consideration of the power consumed when accelerating the vehicle. It would be entirely wrong to base judgment as to essential motor size on an assumed rapidity and ease of get-away. A buyer can be influenced easily by a demonstration when a loaded truck is starting under way from standstill with second or high gear in mesh, although in reality ability to do this indicates merely uneconomical action during average service conditions. Starting, as well as the propelling of a vehicle, imposes certain requirements on the motor torque, not its power. The favorable shape of a motor torque curve has been explained, dropping gradually from the lowest revolution per minute on. This gives a double advantage in starting the car with the motor running comparatively slowly. On the other hand, it is often profitable to use flywheel inertia to assist in making the start or overcoming some other increased resistance of short duration. A torque curve having a rise at its beginning makes starting somewhat easier than the gradually dropping one because it is apt to give greater torque values in a certain range of revolution per minute after its maximum. Combination of the torques and flywheel inertia in connection with a slipping clutch gives a quicker start, with the faster running motor with the greater torque, but, as stated above, the rising and subsequently dropping torque curve shape is not favorable to economy and the distribution of drive ratios.

Quick acceleration in congested traffic is more important in a pleasure than in a commercial car; it causes some overwork of the motor and adds severe requirements of efficiency of the general brake system, which ought to cause a stop at least as quick as the time of acceleration; otherwise a heavy vehicle with a great momentum gained by acceleration brings very undesirable conditions into traffic. It is proper to run a heavy truck with low gear in mesh in a tight place, when a comparatively small motor will develop sufficient torque and power to keep the vehicle within reasonable limits of acceleration without disturbing the general traffic order. At any rate, the question of acceleration can be introduced as an item of some importance into the selection of the proper motor size only in those circumstances when frequent stops and starts are anticipated during service. In all other cases it would prove of too little advantage to gain time by a rapid start with a larger motor in the car, as against the lack of economy due to running continuously under a small percentage of its power development capability. The possibility of frequent starts being practically excluded in the service of trucks of large carrying capacity one can omit entirely any consideration of power required for acceleration when determining their motor sizes. On the contrary, motors for delivery wagons, passenger buses, etc., should be selected so as to assure reasonable promptness during starts, which means using larger motors comparatively.

Returning to the motor size finally indicated as the result of the example figured hereinbefore for a 3-ton truck, its dimensions, 3 1-2 inches by 5 1-4 inches, seem much too small, particularly when comparing them with those of present practice. However, one is more accustomed to the latter, although they have been adopted without investigating actual normal and extreme requirements. As stated before, it has appeared safe to use an oversize motor in a truck; thus one did away with possible future criticism as to lack of power. With increasing attention being paid to economical performance in service, which ought to influence the scope and extension of commercial car application, the matter of properly selecting motor sizes according to service conditions rises in importance. It can cause not only a general revision of truck motor sizes, but introduce a greater variety of motor sizes for cars of the same capacity, of the same make, whereby different motors will be selected in accordance with prospective service. Thus one may become gradually educated to the fact that the use of a four-cycle, four-cylinder, 4 3-4 inches by 6-inch motor in a 3-ton truck regardless of the prospective service means at the least a serious disregard of economy. A buyer of commercial cars will do well to look into this side of the question to assure himself that the extra expense connected with the oversize motor remain within allowable limits. The proper solution of the question requires considerable experience and ability. Nevertheless introducing principles of "scientific management" into the matter of purchasing commercial cars is justified, not restricting their application to the organization and management. In this connection it may be mentioned that although this article deals with the question of motor size only, a similar investigation could be made of the other parts and constructive features of the vehicle.

Torque Determines Motor Size

It is of interest to consider in what cases motors of the present large sizes can be worked to their capacity economically, taking for example, a 4 3-4-inch by 6-inch motor in a 3-ton truck. This motor has a piston displacement of about twice that of a 3 1-2-inch by 5 1-4-inch motor, and ought to be treated as capable of delivering twice the torque of the latter under otherwise equal conditions, including piston speed. It can propel the loaded vehicle over a level road of 40 pounds per ton tractive resistance at a speed of 17.5 miles per hour; up a 10 per cent. grade with 100 pounds per ton resistance at a speed of 2.25 miles per hour; and the empty vehicle at 26.5 miles per hour. With the same lowest gear ratio as with the small motor this larger one can take the fully loaded car up a grade of 20 per cent. (11.4 degrees incline) with a tractive resistance of 200 pounds per ton, which corresponds to a soft, muddy road surface. There is no doubt that conditions might be met in practice when reliable service could be rendered only with a motor not smaller than this, but that does not justify its use in all cases. As to the methods by which the proper motor size can be determined, one can say that attention should first be paid to the developed motor torque and its elapsing through a wide speed range, leaving the motor power to play a secondary rôle. It is the required motor torque and not the required power which determines the economical motor size for a commercial vehicle, as well as the suitable drive ratios.

Discussion on the Batzell Paper

C. T. Meyers, General Motors Company, in opening the discussion on the paper, said:

The views in this paper should be attractive to any one who has a truck. Motors in American trucks are too large for the loads they have to draw. The American motors are too much along the line of touring car types. They deliver far less than the maximum torque under ordinary conditions. We can reduce the piston displacement 33 per cent. in many of our truck motors and still have enough power. Mr. Batzell suggests for a 3-ton truck a four-cylinder motor with 3.5-inch bore and 5.25-inch stroke. I do not think this would give enough power with our gearset limitations. I think a motor of this size would be ideal in a 1.5-ton truck carrying a 2-ton load. After many experiments with a 3.5-ton truck with a 5x5-inch motor we put in one 4.5 inches square and carrying a 10.5-ton load, took grades of 3.5 to 4 per cent. on direct drive with a 6.5 rear axle ratio. I should like to give data we have collected on trucks to prove that the motor is rarely called upon to show its maximum torque. When using the too large motor we are burdening the truck with additional weight and making the owner spend too much for gasoline. Many important changes can be made in gearbox design. A motor truck speed of 13 miles per hour is perfectly feasible under many conditions, but the average truck of today operated over average city streets and average country roads by the average driver will not operate at the best advantage to the owner at such a pace. Our 5-ton truck works at 9 and 9.5 miles per hour. If all of these matters are taken into consideration by designers it is possible to make a good truck at less cost to the maker and owners.

David Fergusson, Pierce-Arrow Motor Company, said: The motor should be made as small as possible in order to do the work, and in trucks it should be kept at as constant speeds as possible. Regarding motor size, it should be such that it has not to work at over 75 per cent. of its capacity for a 10-hour day; otherwise it will not endure as it should. Experience is the main factor in determining motor sizes in trucks. We have over 200 in daily service, many of which have been working for over 18 months. For 5-tons the motor is four-cylinder, 4.875 by 6 inches, and it gives good results. It is an easy problem to determine the necessary motor size for a commercial vehicle when you have the correct size for one truck model. I think 18 miles per hour for a 2-ton truck, 15 for a 3-ton size, and 12 or 13 for a 5-ton, satisfactory. The truck motor must last longer than that of the pleasure car; it should readily last for 10 years and many more. If you put in too small a one, it will not last that long.

Mr. Bachmann's Brief Comments

E. R. Bachmann, the Autocar Company: I have been with our company since the inception of the truck movement, and think Mr. Batzell has offered material to furnish the basis of some very valuable thought for commercial vehicle practice. The correct size of a motor for a truck calls for more care than in a pleasure car. The necessary motor size in a pleasure car depends on the speed that the buyer wants, whereas in the commercial field it is solely a problem of transportation, and the various truck parts must be so proportioned as to transport goods at the lowest possible cost. Our company made an analysis of the different motors and trucks at the recent commercial vehicle shows, and the motor sizes in relation to truck load varied so much as to conclusively prove that the industry is in a very young state. In many trucks the motors are too large for the gearbox used; these must be proportioned. If a truck designer in laying out a truck installs a motor capable of taking all grades from the Atlantic to the Pacific on direct, he is wrong and his action is as absurd as that steam engineer who would use the same locomotive to transport merchandise over the Rocky Mountains that he would use on the plains.

Charles E. Duryea, C. E. Duryea Company: I have been building occasional delivery wagons since 1898, and I am in favor of keeping the motor speed low, and I have always aimed at designing a motor to give high torque at crankshaft speeds of 600 or 800 revolutions per minute. The difference between the high-speed motor and the low-speed motor is that between the race horse and the draught horse. We should have the draught horse type of motor. I favor the two-cycle type, as it fills its cylinders better at low crankshaft speeds and so pulls better than the four-cycle. You cannot get as much power out of a two-cycle at high speeds as a four-cycle, but more at low speeds.

J. G. Perrin, the Lozier Motor Company: The relation of tire life to truck speeds is a vital factor. The motor can be made to drive the truck at high speeds, but the life of tires under such service is limited. We must calculate the critical point in this regard.

Mr. Birdsall Gives His Views

E. T. Birdsall, Detroit, Mich.: I agree with Mr. Batzell. I favor a small high-speed motor with crankshaft, crankshaft bearings and crankcase parts of size for a very large motor. To be explicit, I favor using a motor of 3.75-inch bore and 5.5 or 6-inch stroke, and making these parts as heavy as would ordinarily be used in a 5.5 by 5-inch motor. This would do for a 3-ton truck, the motor operating at 1200 revolutions per minute. In the matter of truck speed in miles per hour it resolves itself solely into what you want to pay for tires. If, like some truck owners, you propose to use it for 18 months, working it 24 hours out of the day and at highest speeds, so by that time you will have got your money out of it and be ready to buy a new one, as some do, because they vainly imagine it is cheaper, then speed is everything. A 5-ton truck should not work at over 9 miles per hour.

Howard Coffin, Hudson Motor Car Company: The foundation of this matter is not a question of cylinder bore, but one of piston speed in feet per minute. It is a question of determining the speed limits for cast iron pistons to work against cast iron cylinders and the experience of big engine practice has settled this question, and why should we throw such information to the winds? Our basis of design for a truck motor should be the same as the basis of design on which makers of large motors have been following.

Henry Souther, New York City: The weight of the truck motor with relation to the weight of the truck is important. We made a mistake in the pleasure car field; we began with too light motors and then made them heavier. In the aviation field the makers started with too light motors and are now making them heavier; and now in the truck field the same error is being committed. The truck motor must run steadily and longer than the pleasure car one, and we must make the parts larger and heavier and use better materials. These factors must be taken into consideration in connection with low piston speeds. Such a motor will last.

W. A. Brewer, London, Eng.: In England we built trucks too light at the start. Now we use a 4-inch bore on 3- to 5-ton trucks. The cylinder sizes are not the fundamental point from which you carry out your truck design. With us the depreciation in trucks averaging 20 miles per day in heavy service, has been in the replacement of small motor parts or accessories.

Worm and Helical Gears As Applied to Rear Axles

By Frank Burgess, S.A.E.

An Outline of the Qualifications Necessary in an Efficient Worm Gear, With a Description of an Apparatus for Testing Same Before Installation

FRANK BURGESS by reading a paper on "Worm and Helical Gears as Applied to Rear Axles" struck a responsive chord in many listeners, and the discussion which followed the reading of the paper was comprehensive. The paper is as follows:

European practice, extending over a period of 15 years, has given ample evidence of the eminent success of the helical type of gearing, and I feel confident in saying that in the near future a large percentage of the cars in the United States will be equipped with this drive. Mileage records of 50,000 to 124,000 have been established.

Regarding the terms worm, helical and spiral I would say that spiral gear is the term commonly given to a gear the teeth of which have a uniform twist parallel to the axis, although for technical correctness the word helical should be used instead of spiral. A spiral is a line generated by progressive rotation of a point around a fixed axis, with a constantly increasing distance from the axis. Two forms of the spiral are the plane and the conical. Kent states: "When the axes of two helical gears are at right angles, and a wheel of one, two or three threads works with a larger wheel of many threads, it becomes a worm gear, or endless screw, the smaller wheel or driver being called the worm and the larger or driven wheel the worm wheel."

I suggest standardization of terms, and that to avoid confusion any gears of the helical type transmitting motion with shaft angle at 90 degrees, with a speed reduction less than 10.1, be termed right-angle helicals; and with any other than 90 degrees shaft angle the term helicals, stating specifically the exact angle of shafts. If shafts are parallel the term helical spurs should be used.

As the term right-angle helical is not as convenient as the term worm gear, and inasmuch as for automobile work most ratios will be less than 10-1, with 90-degree shaft angle, I would suggest the term helical gears as most appropriate. Otherwise it would be better to use the general term worm or worm gear to include all reduction ratios, even as low as 1-1. This matter should be settled promptly one way or the other.

The History of the Worm Gear

Worm gears were used at an early date. Archimedes is credited with the invention of the screw in 250 B. C. for the purpose of launching a large vessel built under his direction. Hero of Alexandria in 150 B. C. showed the screw in several forms of his spiritalia. About 1600 Jacobi Bessoni designed a rude lathe for cutting wooden screws. Important improvements in screws and screw-cutting machinery were made by Jesse Ramsden, Henry Maudslay, Sir James Barton, Sir Joseph Whitworth and William Sellers.

During the past 20 years great strides have been made in the development of helical gears. The adoption of these gears for parallel and right-angular drives has made practically a new element in machine design. Until this form of gearing was made commercial by the invention of special machinery suitable for economical production, there was considerable reluctance on the part of the manufacturers to adopt the helical gear.

The principal reason for the adoption of the helical form of tooth appears to be its peculiar quality of silence, regardless of speed or load. With the best methods of design and assembly, great durability, strength and efficiency are obtained.

I believe that on all styles of cars in the United States the worm gear could be used successfully for rear axle purposes.

The successful worm gear should embody the following qualifications:

1. Cheapness of construction.
2. Strength for resisting shocks
3. Hardened and smooth surfaces for durability.
4. Material of a suitable composition to reduce friction.
5. Simplicity of construction and mounting.
6. Perfect bearing condition.
7. Noiselessness at any speed or load.
8. Reversibility.
9. Lightness in weight.
10. Efficiency in power transmission.

Granting that there is some argument against the worm in regard to trucks as to the dead axle proposition, this could be overcome by using the worm gear on each end of the axle, the same as sprocket wheels, having a double worm gear drive in place of the cumbersome chain drive. If at first slightly more expensive than the chain and sprocket drive, less repairs will more than make up the difference. Care should be taken to have accurate and first-class bearings, both radial and end-thrust.

Considerable discussion has arisen in regard to the relative merit of the straight and Hindley types, the latter having been first used by Hindley, of York, England. In my opinion both can be used successfully, although each has its own advantages and disadvantages. For most purposes, particularly where considerable power is to be transmitted, the Hindley has the advantage, but with ordinary machinery it is somewhat more difficult to obtain the same degree of accuracy that can be obtained in the case of the straight type.

From tests made there is no question but that there is a larger bearing surface on the Hindley type of worm than on the straight. Therefore this type of gearing will for the same pitch present a bearing of greater durability and manifestly heat less than the straight type, particularly under heavy load.

With first-class bearings the Hindley type has the advantage, as a smaller and lighter gear can be used, thus reducing expense, especially if made up in large quantities

The hardening process for the worm should be such as to cause the least amount of distortion, careful methods of heat treatment being employed. The benefit of this is that the gear teeth of the Hindley type which it is impracticable to grind can thereby be lapped, making the teeth concentric with the hole, which is very essential in a worm of this type. The gear should have a mirror-like polish. In this way with hardened concentric polished tooth surfaces the Hindley type presents a better surface of contact than the best form of straight worm, even though the latter is finished by grinding.

Details of the Hindley Type

The gear is flanged on one side with eight lugs with hole in the center of each for mounting on differential casing. There is a slight shoulder on each side of this gear so that the differential casing will form a double web, stiffening the gear so that there is no opportunity for side vibration, thereby reducing the bronze metal to a minimum.

The worm gear should be made of a special mixture of hard bronze. The gear should be slightly polished after being cut to insure a perfectly smooth glazed surface to mesh with the hardened polished worm. This set of gears, properly housed, with ball bearings and the right lubricant used, will give an efficiency of at least 90 to 95 per cent.

A simple method of testing the gears for efficiency without elaborate apparatus is to run them in their regular housing, containing a bath of oil, subjected to load to be transmitted. If they do not have a high temperature after running several hours they indicate high efficiency and suitability for the given purpose.

Proper Testing of Motors, Determining Various Factors

By Herbert Chase, S.A.E.

Finding Friction Losses in Motor, Analyzing the Exhaust and General Standardization of Testing Methods Are Among the Needs of Present Practice

ONE phase of the recent S. A. E. meeting which will interest every car owner, every car maker and every car salesman, was the appointing of a committee to investigate the question of motor testing and submit a report on the possibility of standardizing to some extent motor testing. At present there is anything but standardization in this work, with the result that motor tests mean little and have no basis of comparison. The feeling is strong for uniformity for purposes of comparison. At present many of the tests have little meaning and scarcely any permanent value. They are often deceptive to everyone except the person making them, and often he is misled in his conclusions.

This subject was presented by Herbert Chase, in charge of the testing laboratory of the Automobile Club of America, who presented in printed form a voluminous report on the testing of a Pierce motor in that laboratory. This test was very exhaustive and took recognition of frictional losses in the motor, back pressure in the exhaust manifold, heat distribution, pressure drop in the intake manifold, thermal efficiency, constituents of exhaust gases, ratio of air to gasoline weight, power required to drive the motor when idle, and other details. Much of the data presented were more or less discounted, owing to the fact that in the test the regular Pierce-Arrow carbureter was not used and Designer Fergusson of the Pierce-Arrow Company claimed many inaccuracies of motor performance were due to fitting a carbureter not designed for the motor.

Friction Inside the Cylinders

In the matter of the ratio of air to gasoline it varied from 12.2 to 1 to 14.2 to 1 for wide open throttle and 10 to 1 up to 13.5 to 1 for part-open throttle positions.

The test showed that in analyzing the power required to drive the motor when idle, a large proportion of friction in the motor is due to the rubbing of the pistons and rings against the cylinder walls and the friction of gases passing into and out of the cylinders. When the intake and exhaust manifolds were off, spark-plugs out, compression reliefs out and valve covers off, it took 2 horsepower to drive the motor at 600 revolutions per minute, a little over 4 horsepower at 1000 revolutions per minute, 8 horsepower at 1400 revolutions, and 10 horsepower at 1600 revolutions per minute.

The net horsepower necessary to drive the motor when the throttle is wide open and the other openings to the cylinders are only those which the valves allow, as in the regular functioning of the motor when running under its own power, is as follows: At 600 revolutions 2 horsepower; at 1000 revolutions 6.5 horsepower; at 1400 revolutions 12 horsepower; at 1600 revolutions almost 16 horsepower.

When the pistons and connecting-rods were removed the horsepower necessary was as follows: At 600 revolutions one-fifth horsepower; at 1000 revolutions 1 horsepower; at 1400 revolutions 2 horsepower, and at 1600 revolutions 2.1 horsepower.

The test on back pressure in the exhaust manifold showed that it amounted to nearly 8 pounds per square inch at high speeds. The report suggested a dividing of the exhaust manifold in six-cylinder motors because two cylinders are exhausting at the same time, and before one cylinder has completed exhausting, the exhaust valve of the next cylinder opens and some of the exhaust from the latter causes a considerable rise of pressure in the former. This, the speaker claimed, could be obviated by the divided manifold.

Some interesting facts on the operation of gasoline motors were presented in connection with the analysis of the exhaust gases. The manograph used in the tests showed that combustion in the cylinders is seldom the same in two consecutive cycles, and so the expelled gases are not likely to have the same composition. In the test the combustion was not perfect in any run, there being always some CO, carbon monoxide, present; and in some cases the proportion was almost as great as the CO_2. Again, there was in many cases a trace of pure oxygen remaining, as much as 2 or 3 per cent. of the latter existing side by side with the CO. This proved that the mixture within the cylinders was never absolutely homogeneous. Apparently some molecules of oxygen never came into contact with molecules of CO until the temperature was reduced to such a degree that combustion of the latter did not take place.

Finding Volumetric Efficiency

Volumetric efficiency is an important motor test, by it being meant the percentage of total volume gases drawn into the combustion chambers at different crankshaft speeds. To explain: If a motor has 300 cubic inches piston displacement it should, to be at maximum efficiency, raw in 300 cubic inches of gasoline mixture, but it rarely does this. The slower the motor works, the higher the efficiency, but almost proportionately as the speed increases there is a falling off of the volume of gases drawn in, or volumetric efficiency, as it is designated. In the tests the following volumetric efficiencies at different crankshaft speeds were obtained: At 300 revolutions crankshaft speed, the efficiency was 87 per cent.; at 1000 revolutions it was 79 per cent.; at 1200 it was 74; at 1400 it was 71 per cent.; at 1600 it was 68, and at 1700 revolutions it was 64 per cent.

Herbert L. Connell of the Packard Company, in his paper on standardizing motor testing and co-operating in this work, outlined the necessity for such work.

The great present need is for uniformity in the carrying on of each class of motor tests and in the reporting of the same. As conditions are now there is such a divergence of methods that even the most carefully developed tests are only of value for their individual conclusions, and it is almost impossible to link them with other tests for the purpose of drawing conclusions from a broader point of view or for direct comparison. The same condition existed at one time in the field of steam engineering. To meet this the American Society of Mechanical Engineers developed their codes of boiler and power plant tests. These codes have been revised at intervals as conditions and continued study dictated, and have been held as practically absolute and universal standards. Tests carried on under them give engineers an opportunity to pick out relative values, for there is the assurance that the results are really comparable. The buyer bases his specifications and conditions of acceptance upon these standard tests. Although the time has not yet come when the purchaser of a gasoline motor is given or demands standard tests and characteristic curves, yet that time may not be so very far off. A study of past and present announcements shows a tendency to this. At first there were the exaggerated claims of power which the public soon learned to discredit; then came the general rating by the very arbitrary A. L. A. M. formula, and now we notice numerous statements of the formula rating followed by actual brake test readings. The advantage of the old formula method was that it dealt with definite denominations only, and there could be no question as to the methods used behind the mysteriously locked doors of the experimental room. The inadequacy of the A. L. A. M. horsepower rating is well known, but some of those who are stating brake horsepower have based their claims on very low averages, doubtless for fear of reviving the old distrust of such ratings. This state of affairs is obviously unfair to all concerned, but until tests can be conducted in accordance with a code that is universally known to be standard, and to give comparative results, the conservative can hardly do otherwise.

To get back to the engineering standpoint, a very few examples will suffice to show the present state of chaos and the advantages of standard methods. The effect of atmospheric and barometric conditions on the action of a motor has often been observed, but one practically never sees these conditions mentioned in a report. In exhaust pressure measurements comparisons are now impossible because one investigator may have taken his readings 3 feet from the motor with the pressure tube flush with the inside of the pipe, while another may have used a tube extending some distance into the pipe, near the motor, and with the tube end beveled. It is not hard to imagine the effect the difference of position might cause, while in the latter case a velocity factor would be added to the pressure reading. It would really make but little difference if the tube were placed to get the average pressure or not, as long as the method was uniform in each case, for then the results would be comparative.

A standard length of brake-arm has been suggested. This length could be established as that found in the majority of laboratories and would mean only a minor change in the equipment of those not belonging to that majority. Of course, each engineer in his own laboratory knows the relative meaning of his own brake-pulls even without converting them into inch pounds of torque or to horsepower, but think how a standard arm would facilitate the quick grasping of results by the number of our consulting engineers who visit many different test rooms. So much seems ample to suggest the possibilities and need of standardization in this line, and to justify the S. A. E. in doing in its own field what the A. S. M. E. has done so well in power plant work.

Fields Open to Research

Other possibilities are open to a committee on motor testing after a code has been developed and while developing it. One of these is to act as an advisory board in broadly mapping out lines of investigation. This would apply especially in relation to the work being done at the leading technical schools in this country. Here we have well equipped laboratories and well trained men, but it is surprising to know the difficulty advanced engineering students have in settling upon a line of research. The difficulty of picking a particular field is not so great, but to know where to begin and how to get somewhere in the allotted time is the sticking point. Take the hypothetical case of the man who chooses the internal combustion engine. The chances are almost ten to one that his first thought is an investigation of alcohol as a fuel. Why? Because every one who has read the semi-technical magazines, and even the Sunday newspapers, knows that alcohol as a motor fuel is still an almost unsolved problem, from the commercial standpoint at any rate, and it is a peculiarity of youth that it desires to tackle something new instead of building up on an old foundation. Our student probably does not even dream that the engineers responsible for the creation of the smooth-running motor cars do not know the state or condition of the fuel entering the cylinders, and therefore he chooses a problem he knows exists. By the time his "credit" has been earned he probably has not developed a wonderful alcohol carbureter or given any very valuable data to the world, although he has learned a lot about running a balky motor. To carry the hypothetical case further, let it be assumed that the S. A. E. testing code is a standard and that the committee that devised it has been continued and has turned its attention to its advisory function. Our student who has chosen some kind of motor testing, and is further presumed to be in a laboratory which has adopted the S. A. E. code and co-operates with the S. A. E. program when practical, finds that he no longer has a wilderness before him, but that certain paths have been mapped out. Even if the time at his command is relatively short, he may work on a subdivision of a subject that will form a definite link in a definite chain of investigation. You will probably ask if the student and the instructor will take to such a plan. Observations and direct expressions of opinion are emphatically in the affirmative. The why and the how of the student appreciating suggestions in the choice of work has been shown. As to the interest and care that would be given to the work after it was started, there is a psychological factor that will take care of that. Men reaching the point of such work have already learned to be careful, and by that time they have mostly gotten the engineering bug so that anything that looks to be a practical engineering problem instead of the classroom variety is attacked with a zeal that is surprising. There should be no fear that the personal activities of the engineers in charge of the laboratories would be infringed upon. It is not the idea to dictate work, but merely to make suggestions that might well be studied, thereby giving opportunity for a greater common interest.

There are problems of a general nature and of considerable importance which have had to wait while those of more momentary interest were disposed of. Some of these investigations have lapsed because no laboratory of a manufacturer could give the time to carry them through. With co-operation between the technical, commercial and private laboratories a committee should be able to direct the course of a general investigation so as to make it produce definite results and be of a great deal of benefit.

At its last meeting the Detroit Section of the S. A. E. passed a resolution to inquire into the availability of the United States Bureau of Standards for carrying on certain tests of a highly technical nature This was a definite expression that there is need for work that cannot well be carried on at the motor car factory. It also suggests the possibility of including the government departments in the plan of co-operation.

There are two further advantages that would arise if the S. A. E. took an official or semi-official interest in the technical schools. The first is in the matter of equipment. Manufacturers are constantly being requested to loan or donate motors and other modern equipment to the school laboratories. This is often at the request of some particular student, and when he has completed his course the investigation is not continued. Under the new plan the donor would have far greater assurance that the tests on the apparatus would be carried to the end intended and that a real benefit would result from his generosity. The second benefit would be the training gotten by the young men doing the work, for this would particularly prepare them for the motor industry.

Berlin Prefers Electric Fire Engines

In reply to persistent declarations to the effect that the fire department of Berlin and adjacent metropolitan fire district contemplates to introduce gas-electric fire engines, Commissioner Reichel, who has all the development of fire apparatus for this important district completely in charge, makes the emphatic statement that propulsion by electric batteries for the city proper and by gasoline engines for the remoter districts, and for the vehicles used in the administrative work of the fire service, remains the approved system which has been found perfectly suitable. When the automobilization of the rolling stock began in 1906, twenty steam pumps were on hand and it was made obligatory to use them. They were mounted in the electric vehicles. In some instances the steam plants have worn out and have been replaced by gasoline engines driving rotary gear pumps of a construction developed by the department, which never found the centrifugal pumps satisfactory. In some instances a dynamo equipment has been added in order to utilize the gasoline motor better, but the pure electric propulsion system in these cases remains what it was. The fire engines propelled by gasoline engines are also equipped with rotary gear pumps. Summing up, the commissioner writes: "The Berlin fire service now possesses fifty automobiles and needs in all 145. If I did not test everything thoroughly and did not keep all strange influences energetically at a distance, I would, no doubt, by this time have in Berlin the largest museum of automobile fire-fighting equipment in the world. Smaller museums of this description have unfortunately already been collected in several places."—From *Der Mortorwagen*, June 10.

Harking Back a Decade

FROM *The Automobile and Motor Review*, July 5, 1902:

It has been demonstrated recently that a small private automobile stable can be built for about $300 with sufficient accommodations for a single small car. The tendency of the times is to use private automobile stables rather than to patronize the new-fangled garages or public automobile stations.

The Automobile Club of Great Britain and Ireland will put on a road test of pneumatic tires early in the Fall. The conditions call for a run of 3000 miles at 150 miles a day. Hostile observers will accompany each car as well as official observers. Alfred Harmsworth has offered cash prizes of $750. The competing tires will become the property of the club after the run and will be carefully examined. The set of tires that goes through the run under the conditions and appears to be in the best shape after its conclusion will be declared the winner.

The first machine which the H. H. Franklin Manufacturing Company of Syracuse put on the market was bought last week by a New York customer. It is a four-cylinder, air-cooled engine 3 1-4 by 3 1-4 inches and is capable of 15 miles an hour on high speed at 750 revolutions per minute. The extreme speed of the machine is reckoned at about 30 miles an hour. The transmission is by sun and planet gears inclosed in an oil-tight box.

William M. Lewis, president of the Wisconsin Wheel Works of Racine, Wis., announces that his company is perfecting engines which will be used in automobiles to be turned out by the company in January. It is stated that the new cars will be called Mitchell, from the middle name of Mr. Lewis.

The National Association of Automobile Manufacturers proposes to exhibit vehicles made by its members at the international automobile show which will be held in London next March. The association figures on securing a large space and proposes to ship the cars in a single consignment on both ocean trips.

The developments of the past week have shown that the Quaker City council is amenable to reason and as a result of the brake tests, control tests and other demonstrations of various types of automobiles, the proposed ordinance limiting motor speed to 5 miles an hour in Philadelphia has been amended out of all semblance to its original shape. The bill, as it will be presented for action, will probably divide the city into three sections, allowing a maximum speed of 15 miles an hour.

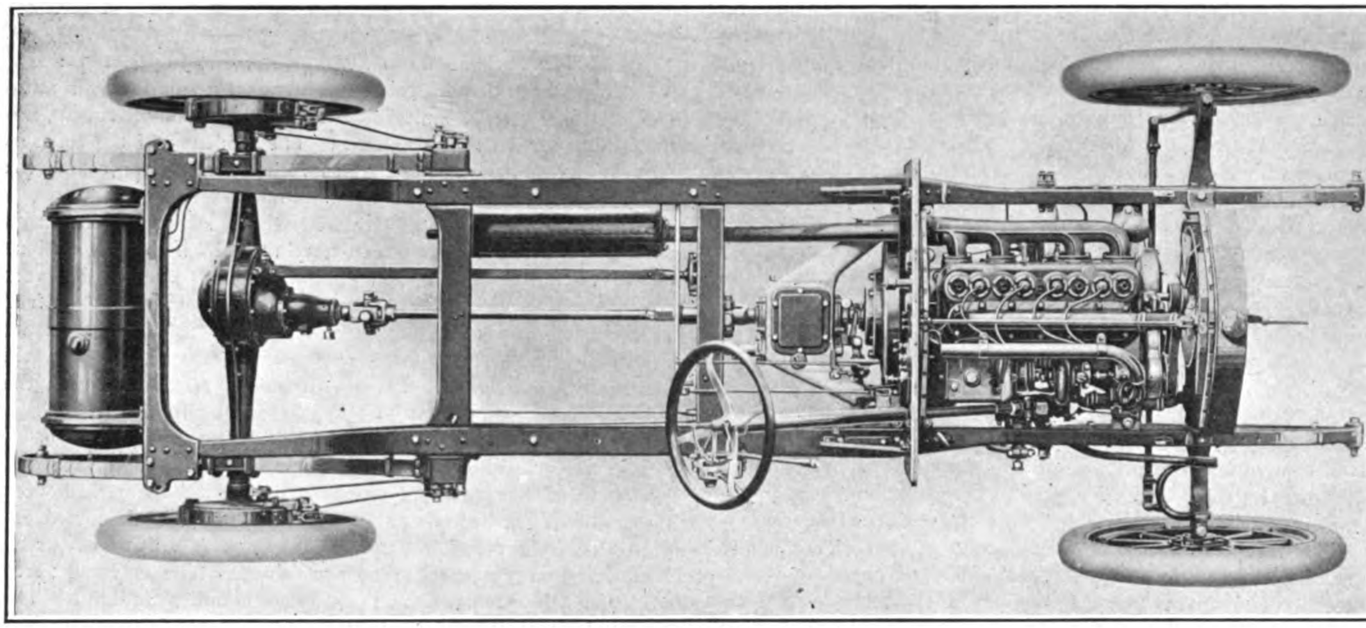
Alexander Winton in his new powerful racing car, The Bullet, set a new world's mark for a measured mile at 51 4-5 seconds. This is 3-5 seconds lower than Fournier's mark. The trial was not sanctioned and the A. A. A. probably will not recognize the record. Mr. Winton has declined to state what is the horsepower of the new machine.

Small Truck to Oust Army Mule

MILWAUKEE, WIS., July 8—That the 3-ton truck will probably never be sufficiently utilitarian for army use, and that if the army mule is to be supplanted by the modern means of transportation, it will be the 1½-ton truck that will be utilized, are deductions gained by Capt. C. R. Williams, U. S. A., in charge of the exhaustive tests of motor trucks which have been going on since February, 1912.

Following the truck run from Washington, D. C., to Indianapolis during last spring, the manufacturers who made the best showing were invited to compete in a more severe test, under actual martial conditions, during the march of the middle western regiments of regular infantry, cavalry and artillery from Dubuque, Ia., to Sparta, Wis.

By the time the army reached Madison, Wis., 124 miles from Dubuque, Capt. Williams came to the conclusion that no truck with a capacity rating of more than 1½ tons would form a feasible means of army transportation. To quote Capt. Williams: "The heavy 3-ton truck has proven a failure for army use. The 1½-ton truck I predict will supplant the army mule."



Chassis of the new Hudson Model 37, showing new location of gasoline tank and drive features

Two New 1913 Hudsons

Model 37, the Four-Cylinder, Is Very Different from the Company's Product Last Year

Details Regarding the New Six-Cylinder Model Not Yet Made Public

THE coming season will see entirely new types of cars on the market under the Hudson name. These are to be two models, a four-cylinder and a six-cylinder type. The features of the new four-cylinder model, which is known as model 37, are in no way similar to those of model 33, which was the company's only type last year. Considerable speculation is in evidence as to the features of the six-cylinder car, the details of which are not yet made public.

The model 37, which is just out, has a new type of motor, the body design is distinctive and much more sweeping in its lines than that of its predecessor. The chassis is entirely new, the self-starting system is different, the location of the gasoline tank has been changed. In fact, it is an entirely new proposition except that the frame is the same as that of the 33 and the gearbox, gears and method of mounting the transmission as a part of the power plant are features which have not been changed.

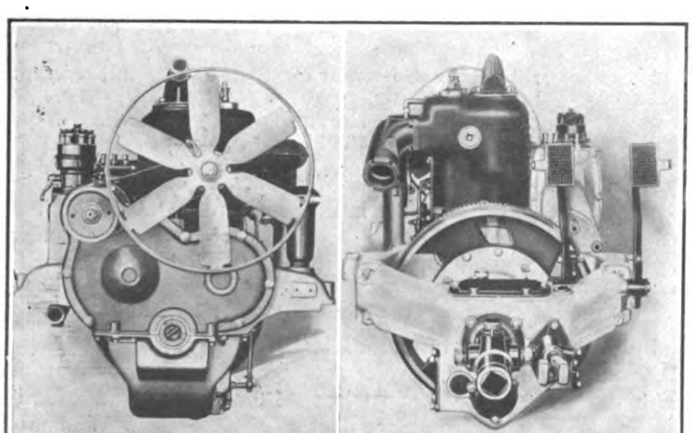


Fig. 2—Front and rear views of new four-cylinder Hudson motor

The motor of the new four-cylinder model is of the monoblock construction, the bore of the cylinders being 4⅛ inches and the stroke 5¼ inches. It has been designed to develop 37 horsepower at 1,500 revolutions per minute. Intake and exhaust manifolds are mounted on the same side of the motor as shown in Fig. 9. Either of these may be removed without in any way disturbing the other. The water outlet manifold WM is of large proportions, while there is a single connection with the cylinder casting for the vertical intake manifold IM, which is water-jacketed, the water being piped from the cylinder water jacket. As shown in the illustrations, the exhaust manifold EM connects individually with each cylinder, running parallel with the top of the motor up to the third connection, where it slopes downward to clear the floor of the car.

Valves Are Interchangeable

The valves are constructed to be interchangeable and are of nickel steel. They have a clear opening of 1¾ inches, this being possible on account of a diameter of 2 inches. The push rods are extra long and the springs are conically wound, the smaller diameters being at the bottoms, as shown at VS. The tappets P are of the mushroom pattern, being in contact with the cam faces at all times. They are provided with means for taking up at their upper ends in the form of nuts and lock-nuts. A casing having two large cover plates completely houses the valves, rods and tappets to the exclusion of dirt. This feature insures the proper lubrication of the bearings, as no dirt can get in to interfere with the effectiveness of the lubricant.

The pistons are of gray iron and have been made specially long in order to better distribute the side thrust between them and the cylinders and thus to reduce the wear on both to the minimum. With the idea of reducing motor vibration, the pistons are carefully balanced before being assembled in the motors.

Nickel steel studs secure the wrist pins WP in place, being made to have a press fit within the bosses to prevent shake. The studs are prevented from working loose by cotter pins. The wrist pin bearings are of hard phosphor bronze, 1 1-16 inches in diameter by 1⅞ inches in length, being pressed into the small ends of the connecting-rods.

As to the connecting-rods CR, they are of drop-forged, heat-treated alloy steel of I-beam section. At the crankshaft ends four nickel-steel bolts fitted with castellated nuts hold the bearing caps in place. In taking up the connecting-rod wear, thin shims are used, and they are interposed between the caps and the rod ends.

A three-bearing crankshaft CS is used with this motor, this being a marked change from that of the former model 33, which was equipped with a two-bearing crankshaft The bearings are of bronze, lined with nickel babbit. The front bearing and the center bearing are each 2 inches in diameter, thee former being 2 9-16 inches in length, while the latter is 3 inches. These two bearings are seen at A_1 and A_2 in the sectional view of the motor. The rear bearing A_3 is the larger, having a diameter of 2¼ inches and a length of 3 15-16 inches. The connecting-rod bearings are 2 inches in diameter and have a length of 2⅝ inches.

Like the crankshaft, the camshaft S is mounted on three bearings of nickel babbit, the sizes being 2¼ inches in diameter by 2⅜ inches in length for the front bearing B_1, 2¼ inches by 1⅜ inches for the center bearing B_2 and 1⅞ inches by 1¼ inches for the rear bearing B_3. The camshaft has been made extra large in diameter to preclude any possibility of its deflection when lifting the valves. The cams are integral with the shaft, and, in addition to the eight which operate the valves, there are two cams which actuate the small horizontal oil pump and the air pressure pump.

Helically-cut steel timing gears are used, being mounted in the usual location at the front of the motor. Oil-tight cases fit over them and they run in oil to increase their silence and wearing qualities. Easy removal has been aimed at in their mounting, which is made a simple matter once the gear cover is taken off.

Flywheel Is Close to Bearing

The flywheel F is so designed that its weight is brought as close to the bearing as possible. This aids in reducing whipping stresses and relieves strain on the shaft. The rim overhangs the bearings completely, as will be evident from an inspection of the sectional drawing of the motor, Fig. 9.

The cooling system is made positive through the use of a large centrifugal pump located on the opposite side of the motor from the valves and on the motor-generator shaft. This pump may be removed by means of couplings at either side without in any way disturbing the other apparatus. This also applies to the packing of the stuffing-boxes. Reference to the illustration brings out the peculiar mounting of the shaft on two bearings, one at either side of the pump and each made integral with the upper half of the crankcase. Due to the monoblock casting, there is only one inlet water manifold connection with the cylinders, the waterjacket space being a unit around all four cylinders. The jacket space has been made ¾-inch wide all around, and, with its very wide type of water outlet manifold, the motor is designed for free water circulation. The cooling fan is belt-driven from a pulley mounted on the end of the pump and motor-generator shaft.

A constant level splash lubrication system is employed for lubricating the connecting-rod bearings, wrist-pin bearings, camshaft bearings, and so on. The front and rear main bearings are positively lubricated by means of the plunger oil pump already mentioned. This pump is operated by a cam mounted on the camshaft and it has a horizontal stroke. There is a sub-bottom to the crankcase where the oil is first led. Four troughs LT hold the oil into which the ends of the connecting-rods dip, and the overflow from these troughs runs down into the bottom of the crankcase, which slopes downward to the center. A sump here collects the lubricant, and it is pumped from here through OP back to the main bearings by the oil pump. The breather pipe and oil-filler pipe are combined and placed over the left front mounting of the motor. There is an inner wall to this pipe through which the oil enters, while the space between this and the outer shell forms the air outlet or breather. Inspection of the sectional view reveals the large oil holes for lubricating the bearings. Two holes G_1 are provided in the front bearing of the crankshaft, two J_1 in the center bearing and one H_1 in the rear main bearing. The pipe connection to the latter is seen in the figure at H_2. The piping from here to the pump and also from the front bearing to it is clearly seen in the halftone illustration of the left side of the motor. For lubricating the lower bearings of the connecting-rods, the holes R are drilled into the centers of the rod ends from the sides of the rods. Some of the oil which is splashed from the troughs LT enters the bearings through these holes. The oil, before entering any of the motor parts, is strained to exclude any foreign matter. A pressure gauge on the dash indicates whether or not the oil is circulating properly.

The motor is fitted with a Zenith carbureter, which is designed for factory adjustment once and for all. To facilitate starting in cold weather, the carbureter is fitted with a dash strangler

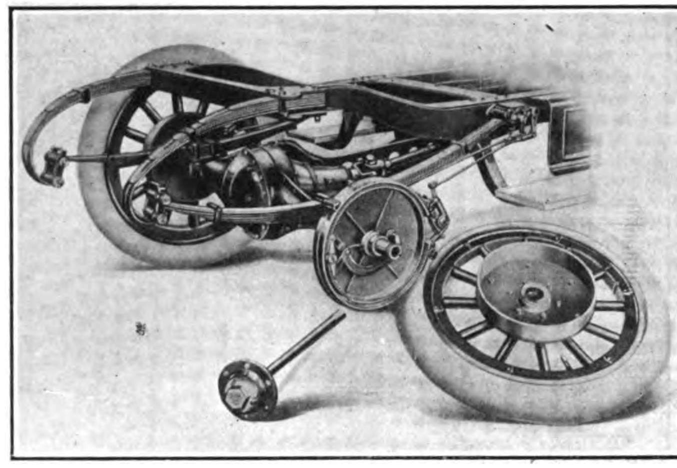

Fig. 3—Rear system of Hudson 37, showing springs and brakes

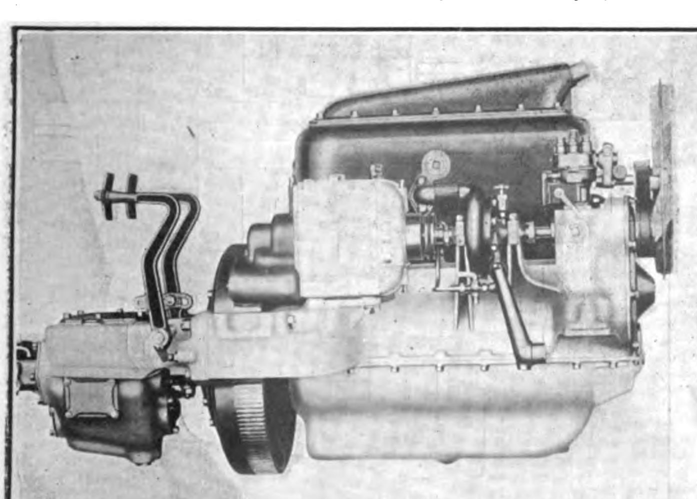

Fig. 4—Right side of motor used in the Hudson Model 37 to be marketed this year

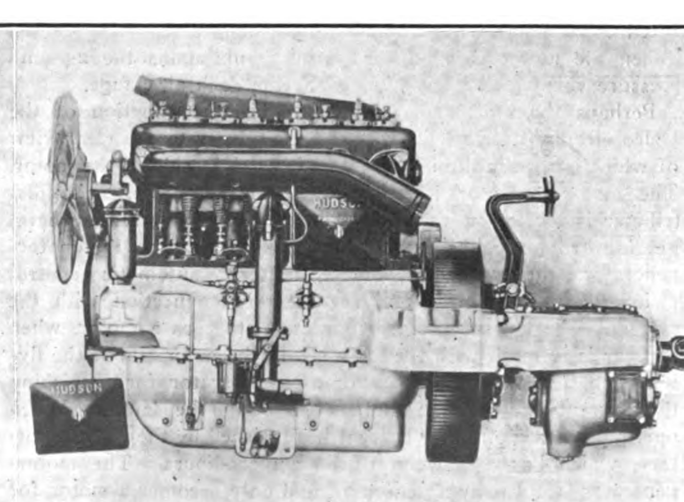

Fig. 5—Left side of the motor

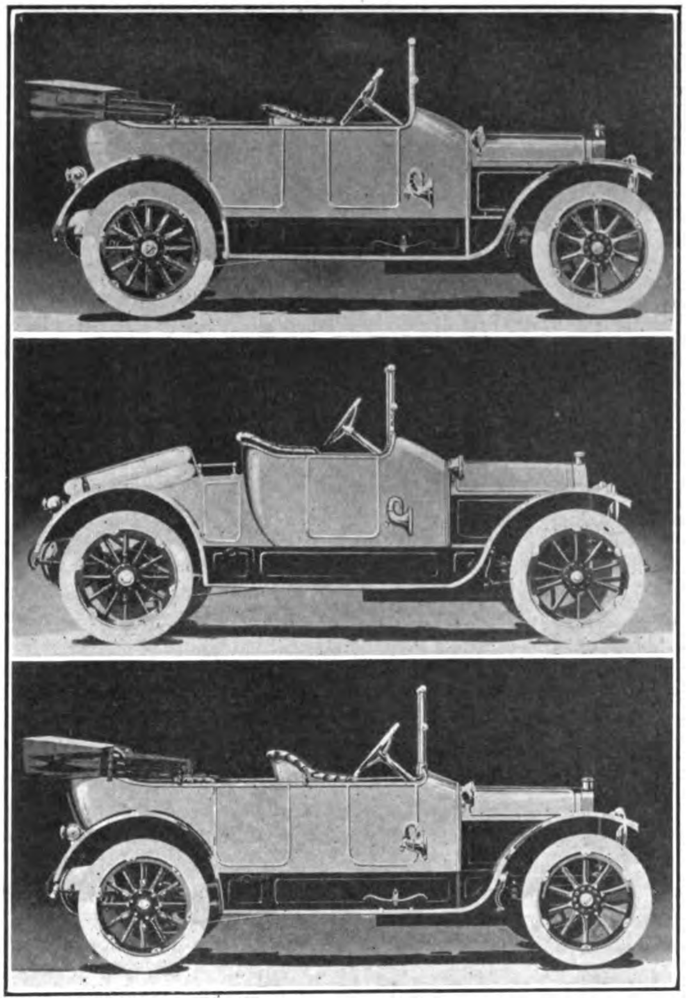

Fig. 6.—Torpedo, roadster and touring bodies to be furnished as regular equipment

which causes an extra-rich mixture to be sent to the cylinders. By means of the air-pressure pump the gasoline is fed to the carbureter under a 2-pound pressure from the gasoline tank, which is located at the rear of the machine under the frame, a new departure for the Hudson concern and one which is rapidly gaining in favor with American manufacturers and users of cars. Two substantial leather-lined brackets hold the tank in place. It has a capacity of 22 gallons and is of cylindrical shape made of heavy-gauge pressed steel. At one end of the tank a gauge is mounted which indicates at all times the amount of fuel in the tank. If necessary to drain the gasoline for any reason, the plug fitted at the bottom of the tank may be pressed into service. When the motor is running, the pump maintains the 2-pound pressure very closely, as indicated by the dash air gauge.

Perhaps the most radical change is in the adoption of the Delco electric starting, lighting and ignition system, a clear view of which is seen in the illustration of the right side of the motor. The motor-generator is mounted to the rear, while the distributer is located at the front, its shaft being driven by bevel gearing from the horizontal shaft. In addition to the motor-generator, there are a storage battery, automatic control switches, cut-out device and regulator in connection with the system. The motor-generator operates either as a motor, when its gear is in mesh with the teeth cut in the outer rim of the flywheel to turn the crankshaft, or as a generator for furnishing the current for ignition and for lighting the lamps. When operating as a motor, the current is furnished by the storage battery, which has a capacity of 80 ampere-hours. The motor-generator is normally a generator, and only becomes a motor for starting. In starting, the driver pushes a button on the dash and presses the clutch pedal forward. This sends current from the battery to the motor and at the same time meshes the flywheel teeth with the motor gear. As soon as this turning over of the engine causes fuel charges to be drawn into the cylinders the motor starts to run on its own power and the operator releases the button. The generator then takes up the work of supplying the ignition current and of charging the battery to its capacity. When the latter reaches this state, it floats on the line and is ready for use in driving the motor. The system furnishes dual ignition, with magneto type of spark for ordinary running and the battery ignition in cases of emergency. A kick switch on the dash controls the operation of either source of current. The lamps may be operated either from the generator direct or through the storage battery. A three-key light switch is placed on the dash for sending the current to the lamps, and a special feature is the placing of a small lamp on the dash for reading of gauges at night. This lamp is in circuit with the rear lamp, and, if the small dash lamp goes out, it is an indication that the other lamp is also out of order. An extension lamp is furnished which can be attached to any of the regular lamp sockets.

Clutch Is of Noiseless Disk Type

The clutch is of a noiseless disk type, self-contained in an oiltight case which is a part of the flywheel. The disks are steel stampings ground 8 11-16 inches in diameter. There are eight disks, which have cork inserts, on the driving member. The driven disks are seven in number and are of plain steel. The idea of the corks is to insure a soft and smooth clutch engagement and to eliminate jerks and slippage in getting under load. The clutch spring is located in a hole bored in the end of the crankshaft. A ball-thrust bearing transmits the pressure to the clutch drums. Small springs are placed between disks to insure their separation when the clutch is released. A half-and-half mixture of oil and kerosene lubricates the arrangement and serves to prevent grabbing and to aid in free action. Lubricant is added through a plugged hole in the casing, which may also be used for cleaning the clutch.

The transmission is the same as that used on the previous model 33. It is of the three-speed selective type, with direct drive on third. A V-shaped member bolts to the rear of the motor, making a unit power plant construction and carrying the transmission gears. Gears are of large size, have strong teeth and wide faces and are mounted in malleable iron cages which prevent them from working loose in the aluminum case. Roller bearings are used throughout the transmission and the gears and bearings are kept running in oil.

Power is transmitted from the transmission to the rear axle through a propeller shaft of nickel steel and two universal

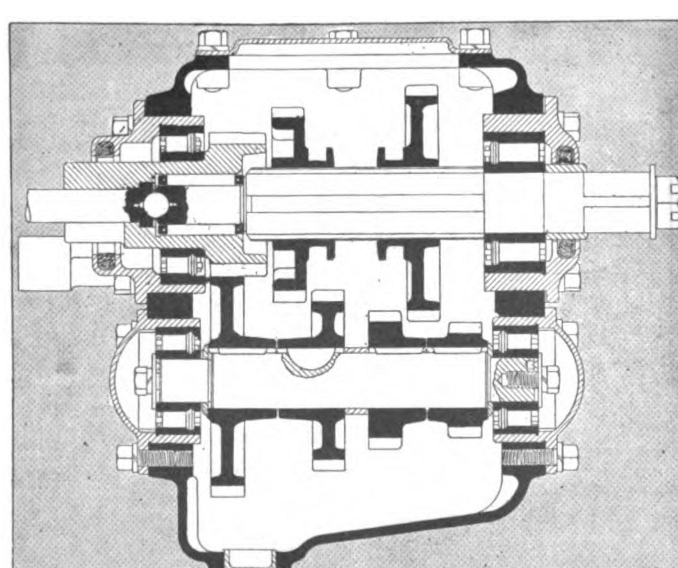

Fig. 7—Plan view of the Hudson gearset

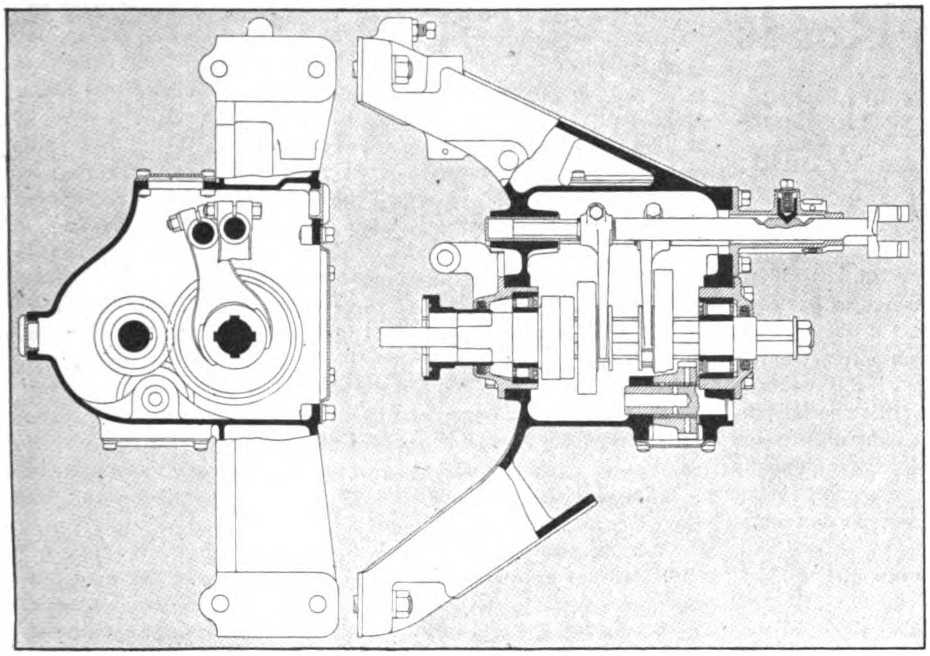

Fig. 8—Transmission and frame used on the new four-cylinder Hudson

joints. The sliding shaft, squared for the universal joint mountings, has a width of 1 3-8 inches across the face and is 5 1-2 inches long.

Specially Strong Front Axle

The front axle is an alloy steel, one-piece rock forging, heat-treated. It is an I-beam section and at its smallest point measures 2 3-8 inches in height and has a depth of 1 1-2 inches. The pressed steel rear axle is of the floating type made by the Bower Company, the two halves being welded together and bolted for extra strength. Driving gears and differential are mounted as one unit, which is bolted to the axle and easily removable without taking the whole axle down. The construction of this unit is such as to allow the adjustment of pinion and driving gear without interfering with the other parts. The pinion and differential case are mounted on large roller and thrust bearings, and the whole runs continuously in a bath of oil. Driving shafts are constructed of nickel steel, oil-treated and due to the floating construction may be removed without disturbing any other parts of the axle. The driving pinion is made of hardened nickel steel and the crown gear is of a specially hardened alloy steel of large section. The plate on the back of the axle may be removed for inspection or adjustment of the differential part. Each end of the axle carries two roller bearings on which the wheels are mounted.

Another departure from former Hudson four-cylinder automobile design is in the use of a substantial torsion arm which runs from the front cross-member of the frame, on which it is mounted in a double spring buffer, to the rear, where it fastens to the axle, as shown in Fig. 1, instead of the torque tube construction in which the propeller shaft was completely inclosed.

The brakes are of the usual double type mounted on the rear wheels. They are 14 inches in diameter and have a 2-inch face. Foot brakes are external contracting, emergency brakes internal expanding. Brakes are lined with special non-burnable lining fastened to the brake bands with copper rivets. The brake drums are pressed steel of one piece type, bolted to the wheels with twelve bolts.

Side frame members are of one piece pressed steel, heat-treated. They are of channel section, 4 inches high, 3 1-4 inches deep and 5-32 inch thick. These members are narrowed in front to give a smaller turning radius. A drop of 4 1-2 inches is made on the rear of the frame in order to secure a lower center of gravity for the whole chassis. There are three cross-members, one at the center of the frame, one half-way back, to which the front shackles of the springs are fastened, and the rear member, which extends out to receive the spring ends.

The springs are made flexible by the use of a large number of thin leaves, which are tongued and grooved to prevent side motion, in addition to which leaf retainers are used. Phosphor-bronze bushings are provided in all spring eyes and the shackles are drop-forged and machined to size. Grease -cups are provided to lubricate the spring bushing. The front springs are semi-elliptic, have a length of 37 inches and a width of 2 inches, while the rear springs are of three-quarter elliptic type and are 50 inches long by 2 inches wide.

The wheels are of the artillery type, the spokes being 1½ inches in diameter, and constructed of second-growth hickory. In the front wheels 10 spokes are used, with a corresponding

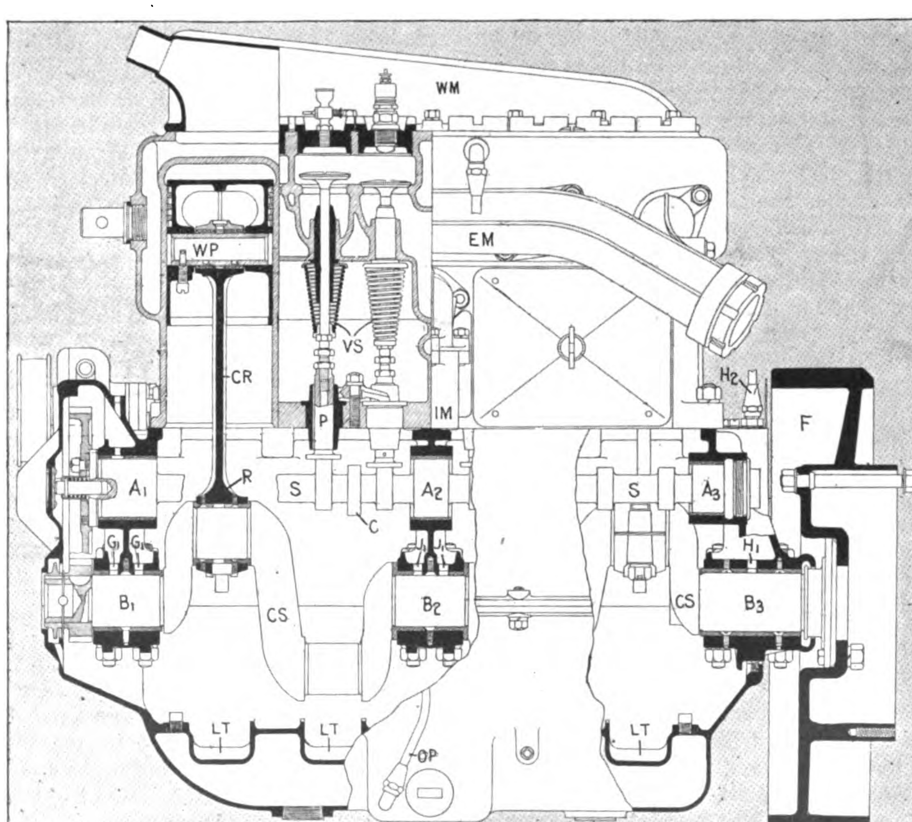

Fig. 9—Sectional diagram of the new four-cylinder Hudson motor

Says We Have No Roads

Lord Montagu Thinks That with Suitable Highways Foreign Tourists Would Flock to This Country

LORD MONTAGU of Beaulieu, editor of the English motoring publication *The Car* and one of the men who has done much toward bringing the automobile into general use in England, has just returned to New York after an extensive trip through the motor car manufacturing centers of this country. When a foreign expert comes to our shores for the special purpose of studying us we can be sure that the searchlight is turned on our tenderest spots; our weaknesses stand out prominently against the background of our successes and an unequaled chance of seeing ourselves as others see us is offered if we but make use of the rays of this same searchlight.

When the staff man of THE AUTOMOBILE saw our distinguished visitor in his apartment at the Ritz-Carlton shortly after his arrival from the middle West, where he had made a critical tour of our largest factories, Lord Montagu had formed concrete opinions regarding the status of the industry in this country. In response to a question regarding the impressions gathered during his stay in this country, his reply showed amply that in his opinion the manufacturing industry had far outstripped an industry which should have kept pace with it; that is, the art of road-building.

"Just think," said Lord Montagu, "here in America you have three-quarters of a million cars and next year you will have a million, and yet you have no roads to run them upon. Not that you do not spend enough money; your appropriations are on a generous scale; still you put all the money in building the roads and hardly any in keeping them up. There seems to be no legislative method of obtaining money to maintain the roads after they are built. I know nothing whatever about your politics, but I do think that your future President, whoever he may be, should heartily endorse a nation-wide good roads campaign. In our country the roads were built before the motor car; in many instances these come down from the early Romans. Our whole road system has gradually developed and we have a regular maintenance tax laid upon the road users. Your roads have come after the automobile and you eat up your appropriations in building, but there is no system by which you tax those who use the road, in order to maintain it.

"Why, if you had good roads throughout the country, tens of thousands of foreign tourists would gladly pay a tax of say a dollar for each 50 miles to come to the United States and view its wonderful scenery. This would mean an enormous inflow of foreign money into the country. The customs house could make arrangements with tourists who intended taking their cars out again so that there would be little expense in that direction. Now these tourists are kept away by the roads. The best roads I have seen during the time I have spent in traveling about the country have been in the vicinity of New York, Boston, and Washington. Throughout the middle West the roads are nearly all dirt and are in extremely bad condition.

"Regarding the motor car industry itself, needless to say it is tremendous; it is growing so fast that it is impossible to tell where we will end. In the cheaper cars especially the manufacturing business is tremendous, as is shown by the great number of your lower-priced cars which are sold in England. We have not done much in the cheap car way, but so far have left that for you to do.

"The use of the car in England is different from what it is in the United States. You use your cars mostly for pleasure driving; we have outgrown that. Our business men use their cars to come to the office. We use them in place of the trains. In our own office there are gentlemen who come from their homes, 40 miles from town, daily in their cars. America has not reached the stage yet where automobiles are used on a large scale for purposes of utility; here they are used nearly entirely for pleasure purposes."

Lord Montagu will leave New York on July 16, having booked passage on the Lusitania.

---

number of hub-clamping bolts. The number of spokes and bolts is increased to 12 in the rear wheels. All wheels are fitted with 36 by 4-inch demountable rims.

Steering is accomplished through a worm and worm gear combination of the irreversible type. The worm gear is integral with the shaft and is of the full gear type, the design being carried out in this way in order to provide an adjustment in case of wear.

Control features are standard, the throttle and spark levers being mounted on a sector on top of the steering wheel as in the usual design. The control is right-hand, the levers being placed at the driver's right inside the body. Clutch and service brakes are adjustable and are found in the usual positions. The steering wheel has a diameter of 18 inches.

As to the standard equipment, this consists of the starting-lighting-ignition system already described, full complement of lights, 12-inch upholstery, speedometer, magnetic gasoline gauge, demountable rims with extra rim and tire holder, 36 by 4-inch tires, windshield, mohair top and curtains, top cover, license-carrier and full set of tools.

The standard body types are the torpedo, touring car and roadster designs. These are all new and distinctively cleancut in appearance. The cowl and dash are made in one piece of sheet metal, no wood being used. The roadster in particular is of pleasing design and is fitted with doors of large size. A new feature is the rear compartment, which is also fitted with two small side doors and through which a suitcase may be slipped, the inner compartment being large enough to accommodate two. Tire brackets are placed on top of this compartment, and, in addition to the tires, a tire trunk may be carried. There is also a door in this part which provides space for the tools, tire chains and so on. In the roadster and torpedo models tire brackets are provided for carrying extras at the driver's right, while the only other apparatus which is carried on the running board is the storage battery of the electric system.

Other body types, such as limousines and coupés, are furnished by the makers on special orders.

The price on the three standard models has been fixed at $1,875, a slight increase over the prices placed on the model of last season.

Delay Buying Licenses Pending Test

JACKSON, MISS., July 9—Much public opposition has developed to the automobile license tax imposed by the last legislature. Thus far only 207 machines have been registered and it appears that the majority of owners will wait until the new law is tested. The state's attorney announces that prosecutions will begin promptly after August 1, when it is provided that all taxes must be paid.

Advocating Good Roads in Ohio

COLUMBUS, O., July 8—The Ohio State Highway Commission and the Ohio Good Roads Federation have started a 3-months' campaign in the interest of good roads building in Ohio. The primary object of the campaign will be to influence the voters of the State in adopting the provision of the Ohio Constitutional Convention of issuing $50,000,000 bonds for road improvement in the Buckeye State. The matter will be voted upon at a special election to be held September 3.

Calendar of Coming Events

What the Months Ahead Have in Store for the Automobilist—Shows, Conventions, Race Meets, Etc.

Shows, Conventions, Etc.

July 10-20	Winnipeg, Man., Canadian Industrial Exhibition.
July 22-27	Detroit, Mich., Cadillaqua Week.
Aug. 5-7	San Francisco, Cal., Pacific Highway Convention.
Sept. 17-20	Denver, Col., Convention International Association of Fire Engineers.
Sept. 23-Oct. 3	New York City, Rubber Show, Grand Central Palace.
Dec. 7-22	Paris, France, Paris Automobile Show, Grand Palais.
Jan. 4-11, 1913	New York City, Thirteenth Annual Show, Madison Square Garden and Grand Central Palace, Automobile Board of Trade.
Jan. 4-11	Cleveland, O., Annual Automobile Show.
Jan. 20-25	Philadelphia, Pa., Annual Automobile Show.
Jan. 27-Feb. 1	Detroit, Mich., Annual Automobile Show.
Feb. 1-8	Chicago, Ill., Annual Automobile Show.
Feb. 10-15	Minneapolis, Minn., Annual Automobile Show.
Feb. 17-22	Kansas City, Kan., Annual Automobile Show.
Feb. 24-March 1	St. Louis, Mo., Annual Automobile Show.
March 3-8	Pittsburgh, Pa., Annual Automobile Show.
March 8-15	Boston, Mass., Annual Automobile Show.
March 17-22	Buffalo, N. Y., Annual Automobile Show.
March 19-23	Boston, Mass., Annual Truck Show.
March 24-29	Indianapolis, Ind., Annual Automobile Show.

Race Meets, Runs, Hill Climbs, Etc.

July 15	Milwaukee, Wis., Reliability Run, Wisconsin State Automobile Association.
July 15-18	Cleveland, O., Reliability Run, *The Cleveland News.*
July 21	St. Louis, Mo., Track Meet.
July 22	Dallas, Tex., Farm and Ranch Tour, Dallas Automobile Club.
Aug. 8-10	Galveston, Tex., Beach Meet.
Sept. 17	Milwaukee, Wis., Grand Prize Race.
Sept. 20	Milwaukee, Wis., Wisconsin Challenge and Pabst Trophy Races.
Sept. 21	Milwaukee, Wis., Vanderbilt Cup Race.
Sept.	Chicago, Ill., Commercial Vehicle Reliability Run, Chicago Motor Club.
Sept.	Washington, D. C., Reliability Run, Automobile Club of Washington.
Sept.	St. Louis, Mo., Track Races, Universal Exposition Company.
Oct. 7-11	Chicago, Ill., Reliability Run, Chicago Motor Club.
Oct. 12	Salem, N. H., Track Meet, Rockingham Park.
Nov. 6	Shreveport, La., Track Meet, Shreveport Automobile Club.

Foreign

Sept 26-Oct. 6	Bourges, France, Agricultural Motor Car Exposition.
Nov. 8-16	London, England, Olympia Automobile Show.
Jan. 11-22	Brussels, Belgium, Annual Belgian Automobile Show. Centenary Palace.

If the proposition is carried the money is to be used to carry out the state-wide plan of road improvement and will be expended under the direction of the highway commissioner. None will go except for the improvement of what is known as main traveled roads from one center of population to another. Later roads leading into the main thoroughfares will be improved under the direction of county commissioners, and it is expected to have all of the highways in the Buckeye State improved within a very few years.

Friends of the movement assert that there is no commercial proposition of greater importance at the present time than the improvement of wagon roads. It is estimated that 75 per cent. of the commerce of the United States starts over the public highways of the country. The average American farm is 10 miles from a railway, although in Ohio the distance is less.

Boom Trunk Road Across Alabama

SELMA, ALA., July 9.—After more than a year's work motor car owners in this city and vicinity feel that they are assured a model road which will span the state from Georgia to the Mississippi lines. Thursday a meeting of all those interested will be held in Demopolis for the purpose of forming the Selma-to-Mississippi Highway Association. The road is to start on the Alabama side of the river just opposite Columbus, Ga., and will extend through Montgomery, Selma, Uniontown, Faunsdale, Demopolis and on to the Mississippi line near Meridian. Missionary work has been done along the whole line of the road during the past year and there is no question but that, when put to a vote, the building of the road will be authorized. The object of the association will be to aid the work done by the counties financially and in other ways.

T. C. A.'s Canadian Frontier Branch

The Touring Club of America has established at Niagara Falls, N. Y., the Niagara Frontier Branch, under the direction of Howard O. Babcock, a prominent and well-known automobilist of that city.

The Touring Club officials decided to locate a touring bureau at this point, owing to its splendid geographical location, and especially for the convenience of motorists touring from the United States into Canada.

Automobilists will find always available at the Niagara Frontier Branch, in the International Hotel, bulletins giving the latest information. not only of road conditions in New York, Ohio and Pennsylvania, but of the main travelled highways in the Dominion.

Motorists in the United States contemplating touring in Canada can receive valuable assistance from Manager Babcock of the Niagara Frontier Branch in securing through the Customs House bonds, permits and licenses which will facilitate their entering the Dominion.

Still After Illegal Tag Users

HARRISBURG, PA., July 8—The crusade made by the state highway department in forcing the automobile dealers of the Keystone State to observe the law governing the use of the dealers' tag is being continued. The fault found is that few, if any, of the men selling cars use any other than the tag that can be used under the law for demonstrating the car to a possible purchaser.

Another point which the highway department is about to enforce is the wearing of the drivers' personal registration pin. These pins have been secured by every dealer, but it is claimed that the section of the law prohibiting the chauffeur from running a car without the pin prominently displayed is a dead letter.

Alco Truck Acts as Pathfinder

KEYSTONE, IA., July 6—The transcontinental Alco assumed the rôle of pathfinder today when the crew in charge agreed upon request from Denver Board of Trade transcontinental route boomers to supply information on roads and bridge conditions. A delegation of tourists from Denver are on their way West, following in the path of the big motor truck.

Iowa bridges have been found woefully weak. The truck fell through a bridge near this city, the second in three days. It was jacked up and pulled through under its own power. Sentiment is strong along the Iowa route for better bridge facilities. The vehicle fell through a bridge 11 miles west of Clinton, dropping 6 feet to the bed of the creek. The crew jacked it up on boxes of soap which makes up the cargo. A runway was built with more boxes and the truck reached the other end of the bridge easily. A group of farmers notified the crew that they had been agitating for a new bridge for some time.

Aside from this incident considerable work was required in replanking and bracing other bridges. A few required block and tackle to keep them secure.

Pope-Hartford Stars at Davenport

DAVENPORT, IA., July 6—The annual hill climb of the Davenport Automobile Club took place on the morning of the Fourth, being witnessed by several thousand spectators, although started at 7 o'clock in order not to conflict with the races of the Mississippi Valley Power Boat Association. There were eight events. The Pope-Hartford carried off the honors of the day, winning four firsts, a second, third and establishing the best time of the day for the steep climb of four blocks, 18 seconds flat. The Cadillac made the next best record with three firsts and a second.

The Engineering Balance Wheel

WHETHER the mature judgment of the conservative engineer or the snap judgment of the masses shall determine the features of design in the new models is a question which the board of managers of not a few factories have not possessed enough stamina to sanely adjust. They have wavered. Their corps of consulting engineers planned a well-balanced chassis, a mechanical creation worked up into a symmetry of efficiency; a resultant in which each part was proportioned with regard to its perspective in the final picture; they completed it, they tested it and found it efficient, equal to the demands and more. Then came the crucial moment: The selling representatives from the four corners of the land met to lift the veil, to analyze the new car, to see it with the eyes of him who meets the public face to face, and with the eyes of him who has to market the product and satisfy the consumer.

They saw and were not content. They objected to the body lines; the convex line must be changed to a straight one, and the concave to a convex. The public would not buy anything else; all selling effort would be increased five-fold if such alterations were not made. The engineer heard and obeyed. It was his to design to sell and not design to drift the company into the shoals or onto the rocks. The public had its way.

A year passed by. Once more the engineering corps fashioned their product, scaling it in accordance with the engineering formulæ and moulding it in harmony with the best accepted practices. But once more the dealer calipered the product through the eyes of the public and once more engineering worth was set aside and public demand pedestaled.

This vacillating program has been going on for several years; each season sees sane engineering dethroned and public taste enthroned, and each succeeding year witnesses the discarding of the public whim of yesterday and the adoption of the engineering fact of the day before. So it continues, not with one firm but with a hundred, every one terrified as to what the public will say. Will they buy or leave it?

Many concerns have experienced this nightmare for several seasons, particularly since the early announcement of models which has resulted in the setting of certain automobile fashions which the makers must make at least a pretense of following. A brief survey shows that the public demands are often wrong; used this year only to be discarded tomorrow; adopted today for a little glittering tinsel and discarded tomorrow because of absolute inefficiency.

This has taken place this year, it has taken place within the last 6 months and it will take place again. It assumes hundreds of different forms. With one maker it is wheels. He has found that a certain diameter of wheel is best suited for his chassis. He has tested it out with such and found it correct. With a larger or smaller wheel the performance of the machine is entirely different, far from being so good. But when the factory aims meet those of the selling force, the engineer has to give way, the other size is put on and the car starts out on its career badly handicapped, just because the dealer imagines that the public wants it.

There must be a line drawn, a line on one side of which the engineering requirements of the designers are placed and on the other side the wishes of the public. At present many factories have never drawn such a line. They will give almost anything to sell and give a different anything each succeeding year. Selling is their only goal. On the other hand, there are those who have stood solid on the rock of engineering practice, and, although they were lagging at times when gauged by public pulse, yet the passage of 4 or 5 years invariably has found them in the lead.

There are too many concerns which are afraid to draw the line. They have not enough confidence to take the step. They hang onto the old, because it has suited the public, until without warning this fickle public casts it aside. The strong concern is the one that decides what is right and then goes ahead, determined not to be led by the public but to make the public think its way. More of such are wanted.

There is a right and a wrong in engineering and the right cannot be followed continuously because the public constitutes the other half of the equation. One construction may be better in the hands of the public than another, at which time it is business acumen to give way to conditions for a time, only as a stepping-stone to the eventual. But where a company is constantly turning east, west, north and south only to take an about-face turn the next season, an engineering balance wheel is needed. The strongest concerns today are those that get things right from an engineering point of view and then start out to convince the public. They continue their warfare until they convince the public. With some, they were not all right, and they generously gave away, not afraid to acknowledge their errors. Others have proved too obstinate, slaves to their own whims, and it is rarely that a whim does not rise to the surface although its period of attention may be very brief.

Not a few concerns lack that business stamina necessary to go out to convince the public. They are afraid others will reap an immediate advantage and they see the rewards of today rather than the cumulative profits of the year. Instead of convincing their dealers, they let their dealers convince them. Instead of progressing, they are merely vacillating. Instead of educating the public, they are merely letting them play the ostrich rôle.

Big Registration in Bay State

Figures for the Past 6 Months Show that Receipts Are Already $110,667.25 Ahead of Last Year—Many New Commercials

BOSTON, July 6.—From the figures just compiled by Edward J. O'Hara, who has charge of the automobile department of the Massachusetts Highway Commission, further evidence is given of the importance and growth of the motor industry in the Bay State.

Although but 6 months have passed the total receipts have run $110,667.25 above the same period for 1911. Not only that but the entire year of 1911 is bettered by $9,039.22. And there are still some heavy registrations to come for many of the summer residents will help swell the total between now and August.

Last year there were 38,907 cars registered. Up to July 1 last there were 40,833. As a lot of men are still waiting for their machines, some of the factories being somewhat behind, the total registrations will go much higher.

The increase has been general along the line, too. For example last year there were registered 3658 motorcycles. Up to date there have been 3759 such machines registered. The manufacturers and dealers have increased also, for there were but 870 named throughout 1911 while there are now 1027, an increase of 157. New concerns are being formed every week, so the figures will increase.

That there has been a steady growth in the number of commercial vehicles sold throughout the state is shown by the figures for these. In 1911 there were about 2000 trucks registered. This year a distinct tabulation is kept on these vehicles and up to July 1 there had been registered 3100 such vehicles.

This shows a gain of about 35 per cent. That there would be more sold if there had not been the agitation to keep such vehicles off the road by hostile legislation, but which fortunately did not pass this year, is the opinion of some dealers. Some of the men who now own trucks have said that until reassured that commercial vehicles would not be legislated off the road they would not invest in more equipment.

In the number registered this year are many old cars that have been turned into delivery wagons. They come under the truck rating. But not being built originally for the heavy truck work they will last but a year or two under the hard service and so they will be displaced by real trucks.

With the state receiving $513,201.67 to date and considering what will be received from fines this year in addition to the total from motor trucks it is estimated that the receipts this year will easily go over $550,000 and they may even reach as high as $600,000.

The following table shows the increase in the motor industry in the Bay State, during the past year:

	Year 1911	To July 1, 1911	To July 1, 1912
Automobiles	38,907	32,212	40,833
Motorcycles	3,658	2,854	3,759
Manufacturers or dealers	870	783	1,027
Operators	11,061	6,370	7,939
Operator renewals	25,345	21,079	24,388
Chauffeurs	4,183	2,241	2,702
Chauffeur renewals	11,361	7,157	7,771
Examinations	6,137	3,321	3,736
Commercial vehicles	*2,000	*1,500	3,100
Total fees	$504,162.45	$402,524.42	$513,201.67

*Approximately.

New Roads in Yellowstone Park

Heyburn, of Idaho, Introduces Amendment to Sundry Civil Bills Asking for Appropriation of $250,000 for the Purpose

WASHINGTON, D. C., July 8—Senator Heyburn, of Idaho, following the introduction of a resolution calling for an estimate of the cost of construction of new roads, or changes in the present roads, in the Yellowstone National Park, in order to permit the use of automobiles and motorcycles therein, without interfering with the present mode of travel in vehicles drawn by horses or other animals, followed it up with an amendment to the sundry civil bill calling for the appropriation of $250,000 with which to make the suggested changes.

So far the estimate asked for from the Secretary of War has not been submitted, but it is expected that it will be in time to be used as an argument in favor of Senator Heyburn's amendment. At present the use of automobiles in the Yellowstone Park is seriously interfered with, due to the restrictions placed on the practice. In addition, there is danger to the drivers of horses or mules when the latter meet motor vehicles on some of the narrow roadways.

Senator Heyburn thinks the Yellowstone Park is destined to be one of the most interesting of spots for motorists and, while he would extend this use of it, he is anxious to protect other travelers.

Senator Jones, of Washington, has also introduced an amendment to the sundry civil bill under which the sum of $35,000 is appropriated for the improvement of the government road between the National Park Inn, in the Mount Rainier National Park, and the point where the government road leaves the national forest reserve.

Wisconsin Gains 3,000 Registrations

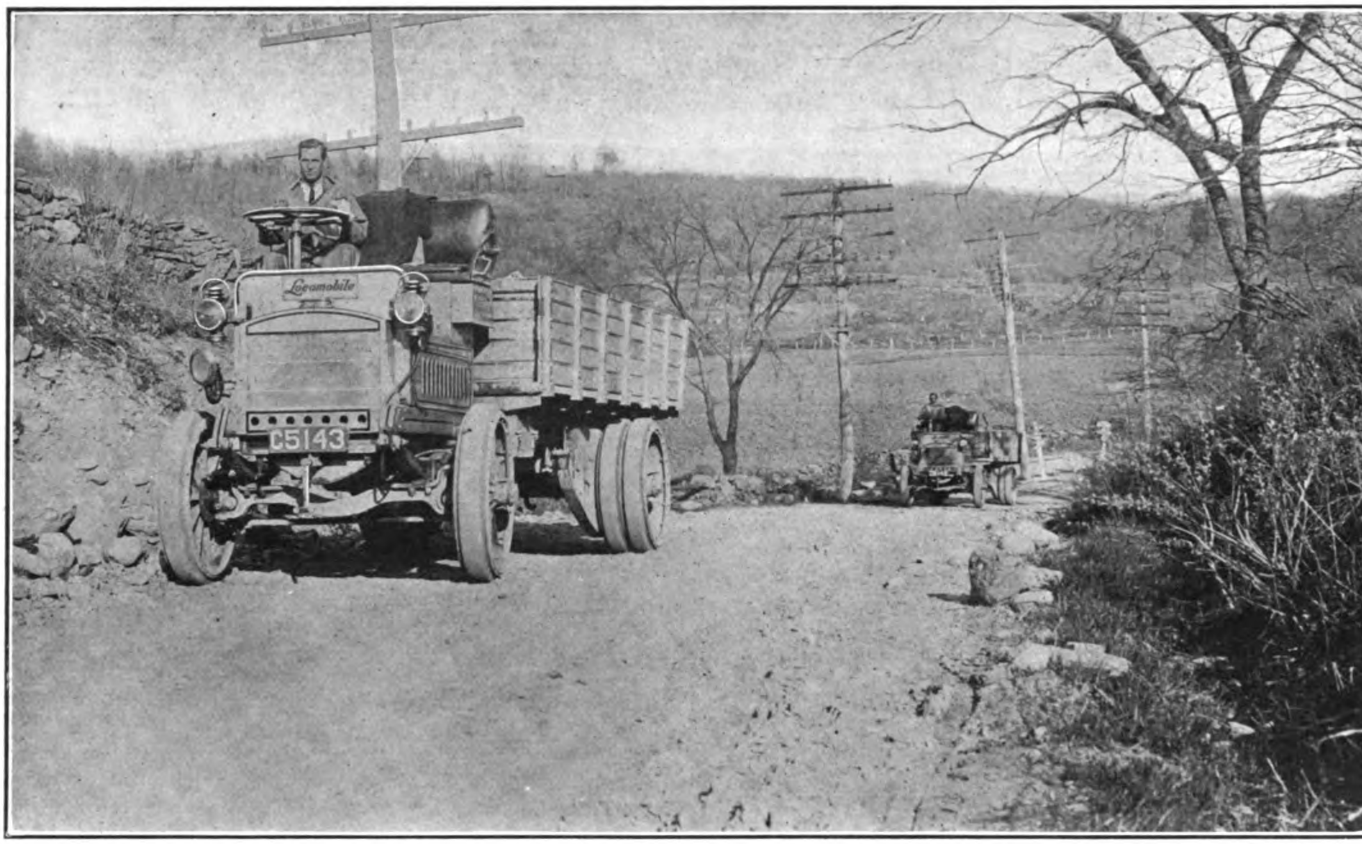
MADISON, WIS., July 8—On July 1, 1912, 21,416 licenses for motor cars had been issued by the secretary of state of Wisconsin, an increase of more than 3,000 over the corresponding period a year ago. In addition, there have been issued 4,100 motorcycle licenses and 972 dealers have been registered. Private owners and dealers pay $5 per year and motorcycles $2 annually, making total receipts by the state of $120,000. After paying the expenses of maintaining the registration bureau, the secretary of state turns the residue into the state highway fund. It is calculated that nearly $100,000 will be raised for highway purposes each year in Wisconsin under the new state aid law, which appropriates $300,000 for the building of highways.

Pennsylvania's Big Registration

HARRISBURG, PA., July 8—The $500,000 mark was reached several weeks ago by the state highway department in licenses and registration fees for automobiles, motorcycles and chauffeurs when the registrar issued license No. 50,000. The record for less than half a year breaks all past registration.

The money is not available for the improvement and maintenance of state highways, but at the next session of the Legislature a bill will be introduced specifically providing that this money and other similar fees can be used for road purposes. There is also $1,000,000 in the fund from past years.

News of the Week Condensed



5-ton Locomobile truck used by Bridgeport Hydraulic Company in constructing dam. Note the hilly country covered

LUNCHEON for Batchelder—A representative committee of Seattle automobilists gathered at luncheon recently in honor of A. G. Batchelder, chairman of the executive committee of the A. A. A. In the company were Judge J. T. Ronald, president of the Pacific Highways Association; Judge Richard A. Ballinger, Judge Alfred Battle, C. E. Plimpton, president of the Automobile Club of Seattle; Joseph Blethen, W. A. Avery, Frank M. Fretwell, R. P. Rice and George Bentel, of San Francisco.

Philadelphia has Motz Branch—A Philadelphia branch of the Motz Tire & Rubber Company, in charge of William M. Shibbs, has been established at 1409 Race street.

Moore Nyberg's Assistant Manager—W. E. Moore has been promoted to assistant general manager of the Nyberg Automobile Works, Anderson, Ind. His position as production manager will be filled by Otto Schultz.

Whiting has Philadelphia Agency—The Philadelphia branch of the Mercer Automobile Company has been absorbed by the Whiting Motor Company, of New York, which will hereafter have the agency for Pennsylvania, Delaware and Maryland.

Willys at North Shore—President John N. Willys, of the Overland-Garford-Gramm companies, has opened his summer home on the north shore of Massachusetts near President Taft's cottage, and he will spend as much time as possible there.

Studebaker Branch in San Antonio—C. W. Hartman, manager for the Studebaker Company in Texas, with headquarters in Dallas, announces the opening of a branch house in San Antonio. This is done with a view of handling the south Texas trade.

C. H. Washburn Dies—Charles H. Washburn, for 35 years associated with the Mitchell-Lewis Motor Company, Racine, Wis., died on July 5, aged 61 years. Mr. Washburn was prominently identified with the evolution of the present Mitchell-Lewis company.

Boorse Interested in Schreiber—Hugo C. Boorse, Milwaukee, Wis., has taken a large financial interest in the Schreiber Motor Car Company, state agent for the Locomobile, Haynes and Hudson. The name of the company has been changed to Schreiber-Boorse Motor Car Company.

Perrin Resigns from Regal—C. C. Perrin, who for the past 3 years has been assistant sales manager for the Regal Motor Car Company, Detroit, Mich., has resigned from that position to accept a position as sales manager with the American Motors Company, Indianapolis, Ind.

Buy Up Duplex Coil Company—F. C. Rueping and R. C. Wells, Fond du Lac, Wis., have purchased the interest of E. J. Huber and J. C. Fuhrmann, principal owners of the Duplex Coil Company, manufacturing coils, magnetos, ignition supplies and electric lighting systems for motor cars, and will continue the business with Mr. Wells as general manager.

Makes Record Time—H. W. Topping, 1093 Summit avenue, St. Paul, Minn., made an automobile trip last week from New York City in 5½ days plus 3 hours.

Sells Accessories in Batimore—Ferdinand C. Latrobe is now handling a general line of automobile accessories in the Oakland Motor Company building, Baltimore, Md.

McCool Wins Promotion—O. N. McCool, formerly sales manager of the Start-Lite Company, Chicago, has recently been made secretary and general manager of the company.

Gets Zilio Agency—The Baltimore, Md., agency for Zilio, the vegetable compound which is used in place of air in tire casings, is now in the hands of H. F. Parker & Company.

Making Over Its Building—The Auto Tire Sales Company, 151 West Sixth street, St. Paul, Minn., has begun to make over its building to get additional space. A. P. Jungck is manager.

Magee Flanders Comptroller—Charles A. Magee, formerly comptroller of the General Motors Company, has taken a position of similar nature with the Flanders Manufacturing Company, Pontiac, Mich.

Salina Now Motorized—The last horse in the Salina, Kan., fire department has been discarded for a KisselKar truck, which has been found much more efficient in responding to alarms than the horse-drawn type of apparatus.

Hawes Joins Everitt Forces—F. W. Hawes has been appointed production engineer for the Metzger Motor Car Company, Detroit, Mich. He was formerly in the engineering department of the Cadillac Motor Car Company.

More Bids Wanted—All of the bids received by the director of safety of Columbus, O., for the erecting of a municipal garage to house the police patrols were above the estimate and were rejected. The work will be re-advertised.

Young Goes to Regal—C. S. Young, engineer and designer for the Lozier Motor Car Company, Detroit, Mich., has severed that connection and has joined the forces of the Regal, with the title of assistant general manager to Fred Haines.

Redwood Falls Tour Begins—The second annual tour of the Redwood Falls Automobile Club began July 12 and will end July 15. The first night stop was at Austin, Minn., and the second and third nights at the Hotel Radisson, Minneapolis. There are about 100 of the tourists.

Builds a Racing Car—C. E. Ross, of the Ross Garage Company, of Columbus, O., has completed a 90-horsepower racer which he will enter in the Columbus 100-mile race August 25. The engine is one of Mr. Ross's own construction and he claims that the car will make 100 miles per hour.

Good Roads Club Formed—The Yakima County Good Roads Association, consisting of all the civic bodies in Yakima County, Washington, was formed recently. The purpose of the association is to work out plans for the location of the roads to be built with the proposed $1,000,000 bond issue.

Many to Tour to Detroit—Invitations to participate in the Cadillaqua parade and festivities have been accepted by automobile clubs in Cincinnati, Indianapolis, Dayton, Chicago, Milwaukee and Grand Rapids in addition to a large number of smaller cities in the state of Michigan. It is announced that all will tour to Detroit.

St. Louis Firms Combine—The Chicopee Motor Car Company, handling the Cutting and Stevens-Duryea in St. Louis, Mo., has consolidated with the Superior Motor Sales Company, holding the Stoddard-Dayton. The combined concern will be known as the Superior Motor Sales Company.

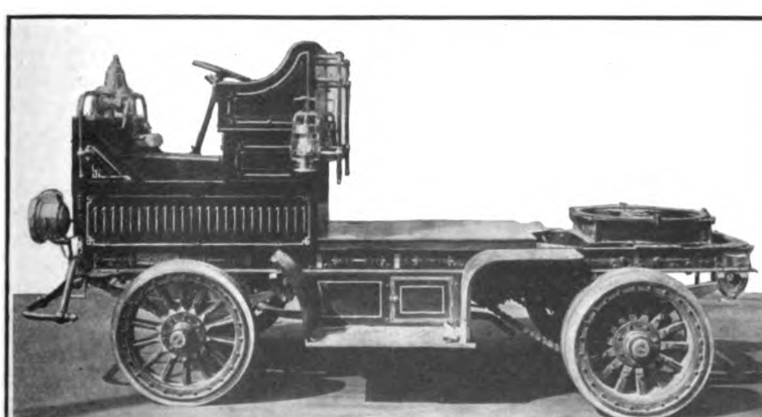
Now Hudson Agents—Walter J. Bemb, central district sales manager, and L. J. Robinson, southern district sales manager, for the Hudson Motor Car Company, have resigned from the Hudson company and have established the Bemb-Robinson Company as distributors for the Hudson line in the vicinity of Detroit, Mich.

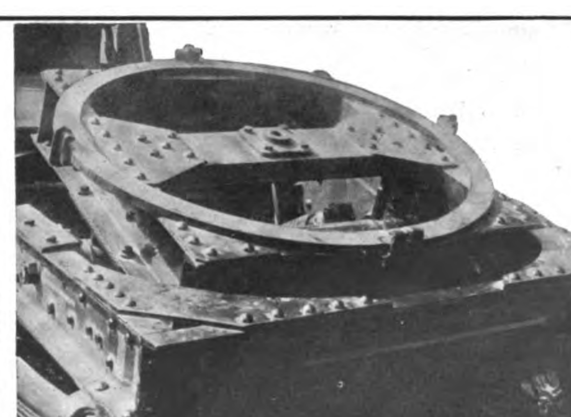
Archey-Atkins to Move—The Archey-Atkins Company will move into a new salesroom at Capitol avenue and Michigan street, in Indianapolis, Ind. The Globe Realty Company has completed a three-story reinforced concrete building for the use of the company, which has the agency for the Hudson, Pierce-Arrow and Detroit Electric.

Big Regal Convention—Preparatory to the distribution of the coming season's output, there has been held at Detroit, Mich., a convention of the traveling representatives of the Regal Motor Car Company. Business sessions were held each day, but mixed in with the more serious parts of the program was enough pleasure to make the gathering one of the most enjoyable as well as one of the most profitable in the history of the Regal organization.

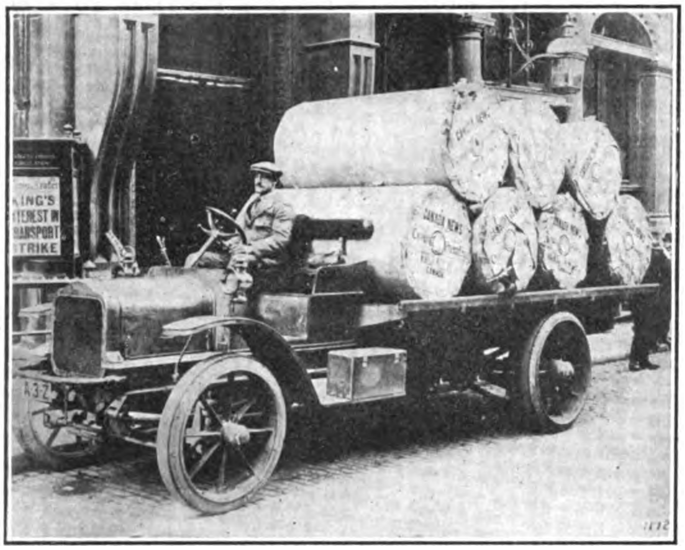
Peerless Men Honored—Academic recognition of the contributions made by the heat-treating department of the Peerless Motor Car Company, Cleveland, O., to the improvement of metals for use in motor cars was given by the Case Scientific School, of Cleveland, recently when it conferred the degree of Metallurgical Engineer upon Robert Abbott and Mark Ammond. Abbott is the chief metallurgist of the Peerless Motor Car Company and Ammond his assistant.

Alco Tractor for Schenectady—The American Locomotive Company has just furnished to the Schenectady fire department an Alco tractor designed to replace horses in drawing hook-and-ladder trucks to fires. Upon the tractor is mounted a fifth-wheel device to which the ladder truck is attached, the latter being guided independently of the tractor. The operation of the fifth wheel is not affected when the tractor drops into a depression of the road. The tractor has a 110-inch wheelbase, and its tire equipment consists of 36 by 5 single solids on front and 36 by 4 dual solids on the rear.





Alco tractor built for the Schenectady fire department, used to draw hook-and-ladder truck. Detail of fifth-wheel device



White truck used by London newspaper during strike

Henderson Offices Are Transferred—The Henderson Motor Car Company, Indianapolis, Ind., has removed its offices to its factory at North West and Fourteenth streets.

Motz Branch in Cleveland—The Motz Tire & Rubber Company, Akron, O., has established a direct factory branch in Cleveland, O. The branch is in charge of Charles Serfass.

Nelson Resigns from Diamond—F. O. Nelson has resigned as manager of the Diamond Rubber Company's Los Angeles, Cal., branch and will shortly enter business for himself.

Work Begun on Atlanta Building—Work was started recently on the new building for the Oakland Southern branch in Atlanta, Ga. The building will be located at the corner of Peachtree and Linden streets.

Crane Chicago Locomobile Man—George A. Crane, formerly with the Knox Automobile Company and United States Motor Company, has taken charge of the Locomobile business in the Chicago territory.

Garford Sells Patrol Wagon—The Garford Company, Elyria, O., has sold a patrol wagon to the city of Newark, N. J. The wagon is a 40-horsepower machine, has a capacity for twelve passengers and a maximum speed of about 45 miles an hour.

Tire Company's Branch Moves—The United States Tire Company's St. Louis, Mo., branch will move to the northeast corner of Compton avenue and Locust street about July 15. This is directly across from the new building of the Firestone Tire & Rubber Company.

Kemps Purchase Repair Station—Harry C. Kemp and Matt C. Kemp have bought from W. D. Rightmire the tire repair station at 1629 Hennepin avenue, Minneapolis, Minn., and will change the name from the Minneapolis Auto Tire Repair Station to the Minneapolis Tire Repair Company.

Republic Branch has New Quarters—The Northwestern branch of the Republic Tire Company, St. Paul, Minn., has moved to a new building at 167-169 West Sixth street. The showroom is 25 by 100 feet. It has a heated driveway for winter use. In the basement is 5,250 square feet of storage space.

Wheeler Now Manager—C. E. Wheeler, formerly connected with the Franklin branch in Boston, Mass., has been made manager of the R. C. H. Corporation branch in that city, filling the vacancy caused by the transfer to the Pacific Coast of William Jordan, who has been manager of the Hub branch for several months.

To Have Sociability Tour—The Mankato, Minn., Automobile Club will have a sociability tour July 16 to Faribault by way of Madison Lake, Elysian, Waterville and Morristown. The Faribault club will meet the tourists on the road and escort them to the picnic grounds. The Mankato club will then return by Owatonna, Wasseco and Janesville.

Minneapolis Club After Thieves—The Automobile Club of Minneapolis, Minn., has paid $500 in rewards to two city detectives for capture of automobile thieves, one of whom is in St. Louis to be brought back. The club paid a large sum toward expenses in the capture of four automobile bandits who have terrorized the city and vicinity for a year.

White Bear Grows Again—The White Bear Auto Company has absorbed the St. Paul, Minn., agency for the R-C-H cars, and will have sale of the cars in Ramsey, Dakota, Washington and Chisag counties. The salesroom will be in the new garage of the company at 161-163 West Sixth street, St. Paul, into which the company has just moved.

Truck as a Strikebreaker—During the recent teamsters' strike in England which tied up practically all the transportation in London, the *London Daily News* employed a White 3-ton truck to haul its supply of paper from the docks to the publishing office. Without the truck publication would have been suspended during the strike. The *News* is now a convert to motor draying.

New Electric Ambulance—Washington, D. C., has added another motor-driven vehicle to its fleet of municipal machines. It is a Detroit-Electric ambulance and is used by the emergency hospital. The machine is the gift of a Philadelphia woman who formerly resided in the national capital. The car is finished in battleship gray, with bird's-eye maple interior and red upholstery and has all the latest hospital equipment.

Marion, Ind.—Railway Motor Car Company; capital, $200,000; to make automobiles for use on railways. Incorporators: G. R. Stewart, J. D. Worth, Eben H. Wolcott, Hiram Beshore, W. G. Worth.

Rye, N. Y.—Jacob Werner, Inc.; capital, $1,000; to deal in automobiles. Incorporators: Jacob Werner, Ellen J. Werner, George J. Werner.

San Antonio, Tex.—Ford Sales Company; capital, $5,000; to deal in automobiles. Incorporators: M. D. George, Clifton George, G. H. King.

GARAGES AND ACCESSORIES

Buffalo, N. Y.—Stewart Motor Corporation; capital, $250,000; to manufacture light capacity trucks. Incorporators: T. R. Lippard, R. G. Stewart, R. P. Lentz.

Clarksdale, Miss.—Essenkay Sales Company; capital, $4,000; to deal in punctureless tires and fill inner tubes. Incorporators: J. L. Hartshorn, J. W. Primrose, I. L. Ledbetter.

Detroit, Mich.—Capital Auto Lock Company; capital, $10,000; to manufacture automobile locks. Incorporators: Benjamin Noble, Arthur E. Schreiter, Walter W. Martin.

Detroit, Mich.—Parker Avenue Garage Company; capital, $10,000; to conduct a garage and repair shop. Incorporators: F. P. Schneider, Joseph E. Weisenberger, Walter M. Trayor.

Dothan, Ala.—Alabama Airless Tire Company; capital, $6,000; to make punctureless tires.

Elmira, N. Y.—International Resilio Company; capital, $50,000; to make and sell a preparation to take the place of air in tires. Incorporators: Raymond Nichols, Daniel L. Tharp, Samuel L. Welch, Henry Collin, Philip E. Lenergan.

Far Rockaway, N. Y.—Far Rockaway Garage; capital, $1,000; to conduct a garage and repair business. Incorporators: John A. Kilgallon, Michael J. Walsh, John J. Walsh.

Club to Post Road—The Automobile Club of Southern California is making preparations to post the road from Los Angeles to Mt. Wilson.

Clement Leaves Spokane—G. B. Clement has resigned as manager of the Spokane branch of the Goodyear Tire & Rubber Company, and will go to San Francisco to engage in the automobile business.

Essenkay in Maryland—The Essenkay tire filler is now being handled in Maryland and the District of Columbia by the Essenkay Sales Company of Maryland, Baltimore, Md. Clarence H. Clark is manager.

Installed in New Quarters—The Missouri Motor Car Company has moved into its new building at 3005-07 Locust street, St. Louis, Mo. The concern handles the Amplex, Alco, Abbott-Detroit and Marmon.

Hadley with Lenox—W. K. Hadley, until recently with the Marion Motor Car Company at Indianapolis, Ind., is now general sales manager and purchasing agent for the Lenox Motor Car Company, Boston, Mass.

Automobile Line Started—A motor car service has been installed between Gueydan and Florence, La. A seven-passenger car is being operated on a regular schedule and initial business is said to be encouraging.

Boston Firm Dissolves—White, Ware & Leatherbee, Boston, Mass., for some time New England representatives for Louis J. Bergdoll Motor Company, Philadelphia, Pa., have discontinued their agency and the firm will be dissolved.

Williams Made Advertising Manager—D. B. Williams, who has occupied the position of assistant sales and advertising manager of the American Motors Company, Indianapolis, Ind., has been appointed advertising and publicity manager.

Death of W. M. Jenkins—Williard M. Jenkins, one of the best known of the Boston motor dealers, and agent for the Abbott-Detroit and K-R-I-T cars in Boston and vicinity, died recently at his home at Exeter, N. H., after a brief illness.

A. N. Mayo Dead—A. N. Mayo, Springfield, Mass., one of the heaviest stockholders in the Fisk Rubber Company, died recently at his home. Besides the interests held in the Fisk company, Mr. Mayo also owned stock in the Knox Automobile Company.

After Good Roads in Montana—Secretary P. N. Barnard, of the Kalispell, Mont., Chamber of Commerce, suggests bonding the state for $10,000,000 to build a uniform system of highways in Montana. Resolutions will be submitted to every similar association for presentation to the Legislature for action.

Combine Against Gasoline Rates—In order to be able to purchase gasoline and oil at better rates than could be obtained from local retailers automobile owners in Texarkana, Ark., have formed a co-operative society. It is claimed that arrangements have been made whereby several cents per gallon will be saved on gasoline.

No Meeting at Atlanta—The Atlanta Automobile and Accessory Association, Atlanta, Ga., has decided to give up its attempt to hold a meeting this summer on the Atlanta Speedway. A canvass of the situation demonstrated that a good entry list could be secured but the scheme was deemed impracticable when the cost of putting the track surface in condition was learned.

Hood Goes to Boston—Wallace C. Hood, formerly sales manager of the Everitt Motor Car Company, has gone to Boston, Mass., to join the firm of J. S. Harrington & Company, New England agents for the Everitt. He will have general charge of sales and distribution from the Boston, Worcester and Providence salesrooms making his headquarters in Boston.

Philadelphia Peerless Branch—A new factory branch of the Peerless Motor Car Company will soon be opened at 245 North Broad street, Philadelphia. R. W. Cook, formerly sales manager of the Philadelphia Peerless agency, will be in charge of the branch. Pending completion of the building the offices of the Peerless company are in the Abbott building, Broad and Race streets.

Special Ice Cream Trucks—The Lippard-Stewart Motor Car Company, Buffalo, N. Y., has built five panel body delivery cars, of 1,500 pounds capacity each, for the Hoefler Ice Cream Company, of Buffalo. The floor of the bodies is lined inside with zinc to prevent salt water from leaking down on the mechanism. Over this zinc is a removable oak grating on which the freezers are set.

Macon's Two-Story Garage—The Harrold Banking & Savings Company, of Macon, Ga., has awarded a contract for the erection of a garage on First street. The building will be two stories high.

Perkins & Corliss Build—A large brick garage is being erected on Western avenue, Gloucester, Mass., for the Perkins & Corliss Company, giving the firm much larger room than it now possesses.

Rothfuss Garage Being Enlarged—The Rothfuss Garage, of Williamsport, Pa., is to be expanded so as to have a capacity for forty automobiles. The addition to the building will be of brick and concrete.

Goltra Opens in Greenwich—Newton R. Goltra has opened a garage on Railroad avenue, Greenwich, Conn., under the name of the Depot Garage & Machine Works, in which a general garage will be carried on.

Council Bluffs' Growing Motordom—The continued progress of the automobile in Council Bluffs, Ia., is illustrated by the fact that Barney Gilinsky is constructing a garage on corner Broadway and Eighth street.

Cohen Buys in New Britain—The garage on Arch street, New Britain, Conn., conducted by H. B. Freeman, of Hartford, has been sold to Aaron Cohen. The purchase includes the Ford agency formerly conducted by Freeman.

To Store Cars in Gardiner—M. M. Spear and W. L. Tozier have taken the lease of the garage building on the causeway opposite the depot at Gardiner, Me., and have opened a general accessory business and storage service there.

Loos' Garage Has No Posts—Loos & Son, Coshocton, O., have moved into their new garage, which is of cantilever construction, so that cars may be driven through the garage without meeting an obstruction.

Fillow Company Expands—The Fillow Auto Company, Danbury, Conn., has purchased two lots immediately east of its garage on Crosby street, and the land will be leveled immediately and used for day storage temporarily. Later on a new structure devoted to the motor truck business will be erected on the property and joined to the company's present structure.

Minneapolis Has Electric Garage—Fred H. Day and Harry I. Murphy have opened an electric garage in Minneapolis, Minn., the establishment being named the Owl. It is a two-story building and covers a space of 70 by 70 feet; the capacity of the garage is for 150 cars. The new electric garage building by the Kemp Brothers Automobile Company will be completed in July.

BIG Chalmers Addition—The Chalmers Motor Company, Detroit, Mich., has approved the first general plans and will start work at once on an extensive addition to the present plant. The immediate operations will consist of the erection of one four-story building which will form a connecting link between the present assembling building and machinery building, both of which are four stories, 60 by 400 feet. This structure will be 191 feet long by 71 feet wide and four stories in height, adding 55,000 square feet of floor space to the present manufacturing facilities of the Chalmers Motor Company. Construction arrangements will also be made for an additional building to be joined to the new structure and to be an exact duplicate of the three main buildings of the factory, which are 60 feet wide by 400 feet long and four stories in height. The new structure will be an all-concrete and steel building. There will be no beams or girders showing anywhere in the interior of the building. The estimated cost of this building is approximately $75,000. Equipped as now contemplated the total cost of the structure will be between $150,000 and $200,000.

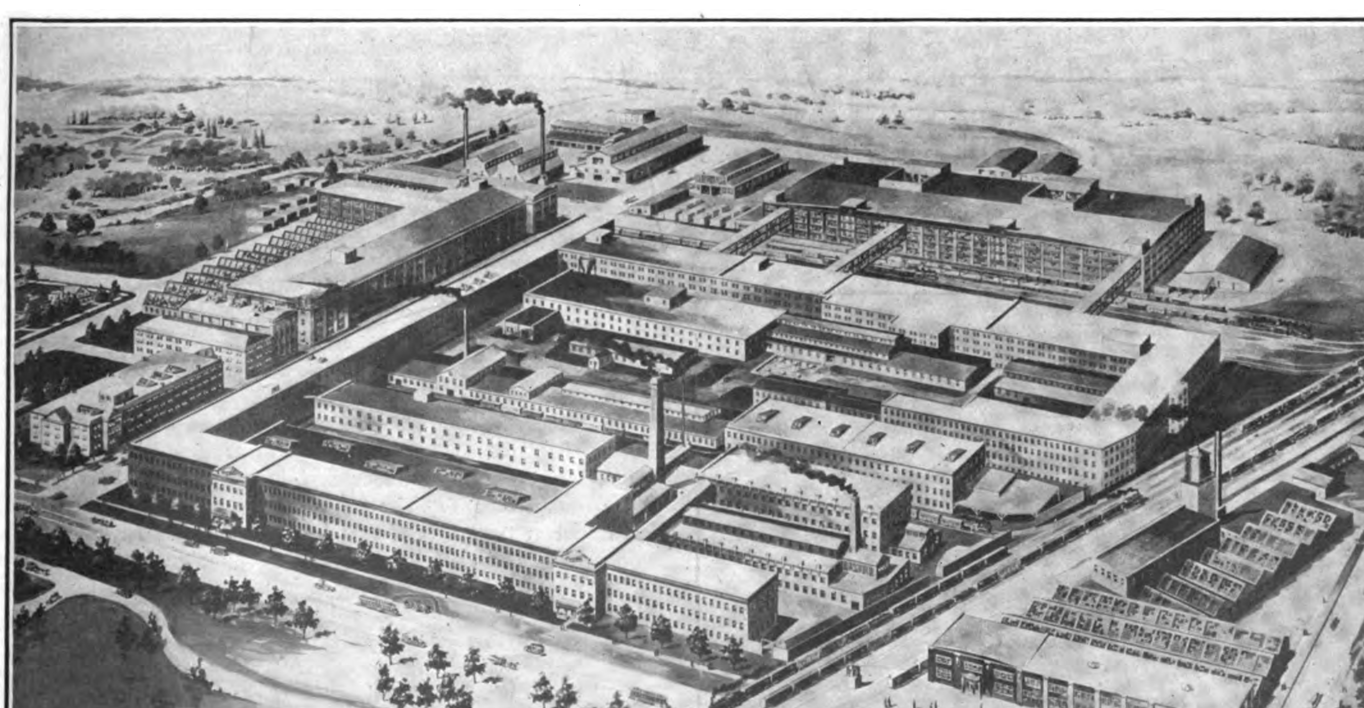
Ford Buys Real Estate—The Ford Company has completed the purchase of a trackage site in Minneapolis, Minn., which will be used for the erection of an assembling and distributing plant for the Northwestern service of the company. The cost of the site is $51,000. Operations will start at once.

Nyberg Works to Make Trucks—The Nyberg Automobile Works, Anderson, Ind., is to manufacture trucks on a large scale. The Nyberg truck will have a 3,000-pound capacity and sell for $2,000. One of these trucks, loaded to its full capacity, will be in the Indiana Four States Tour. This will be one of the most severe tests to which a gasoline truck has ever been subjected, for the route through Ohio, West Virginia, Kentucky and Indiana will present obstacles which only the best of trucks can overcome.

Kissel Increases Capacity—The Kissel Motor Car Company, Hartford, Wis., began work on July 1 on the construction of a new body building shop to be 100 by 100 feet in size, two and one-half stories high, of fireproof construction. The new building will nearly double the Kissel company's body-building facilities, and is made necessary by the 40 per cent. increase in the 1913 production as compared with 1912.

Hess-Bright Company Moves—The Hess-Bright Manufacturing Company has transferred its office to its new factory at Front street and Erie avenue, Philadelphia. Removal of the manufacturing department of the business will be performed progressively during the month of July. The old quarters at Twenty-first street and Fairmount avenue have for the past two years been inadequate for the rapidly growing business of the company, and the new site, which covers some 13 acres, affords ample room for much needed expansion.

Hartford Rubber Works Expanding—As soon as inventory is closed at the factory of the Hartford Rubber Works Company, Hartford, Conn., extensive alterations will take place at that plant. The boiler plant capacity will be increased by the addition of a new building, 50 by 100 feet, which will be built of reinforced concrete. This will enable the company to enlarge its engine power to 3,000 horsepower. Among the improvements planned is an automatic coal-feeding mechanism, a 200-foot smoke stack and numerous improvements of the plumbing. A turbine, driving an 800-kilowatt generator, will also be installed.



Plant of the Willys-Overland Company at Toledo, O., where the Overland cars are made

Manifold-Injector Starter; Vacuum Core Tire; New Model of Gasoline Meter; Coes Special Wrench for Automobile Use; High-Grade Rubber Casings and Tubes

The Blitzen Acetylene Starter

AMONG the many acetylene starters which have been offered to the automobile public of late, the Blitzen starter, Figs. 1 and 2, is especially deserving of mention because of its simplicity. The starter consists of a needle valve interposed in the acetylene lead between tank and intake manifold, this valve mechanism being combined with an electric cut-out. In the cut-away view, Fig. 1, N is the needle, which is made of tool steel and seats on soft metal S1. The needle-valve stem which is screw-threaded to engage the spindle S is actuated by the handle H, and, when the needle is opened by turning the handle as far as possible in a clockwise direction, the handle touches the piece C1. This piece has an extension T which is connected to the low-tension terminal on the magneto, so that when acetylene is admitted to the manifold, the contact of the handle and the piece C1 cuts out the ignition system by short-circuiting the magneto and admits a charge of acetylene to the motor. The acetylene enters through L1 and leaves through L2, and the needle is brought back to its seat by the action of a coiled spring inside the casing C; at the same time the contact of H and C1 is interrupted. The charge of acetylene in the motor keeps the same ready for starting, so that by throwing the switch on the battery the motor is started, after which the switch is kicked over on the magneto. If the motor has been standing for some time, especially with the compression release cocks open, the first thing to do is to close these, give the crank a quarter-turn with the ignition cut out, then switch on the battery and thereby start the motor.

A Thermos Lunch Restaurant

Under the name Thermos Motor Restaurant, the American Thermos Bottle Company 243 West Seventeenth street, New York City, manufactures a touring lunch outfit containing two Thermos bottles, plates, knives and forks for either four or six persons, napkins, salt and pepper shakers and wicker-covered glasses. This equipment is inclosed in a black patent-leather waterproof casing.

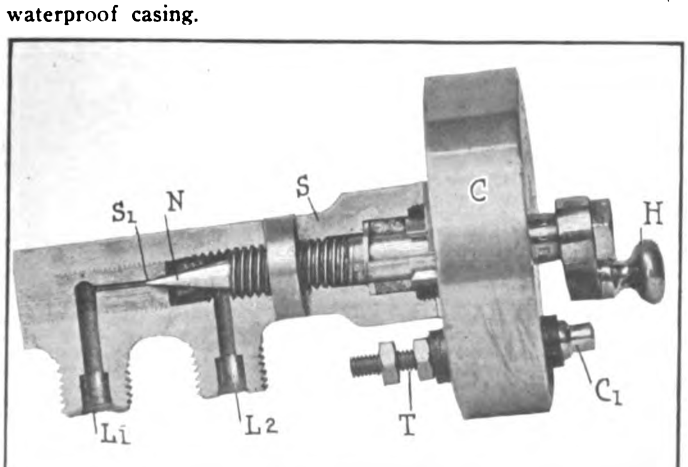


Fig. 1—Distributer of Blitzen starter with one half cut away

Woodcock Vacuum Tire

Substituting an evacuated space for the air of inner tubes, W. J. Woodcock, 102 Gates avenue, Brooklyn, N. Y., has constructed a vacuum tire for automobiles which consists of a rubber core bored with an annular vacuum chamber, the cross-section of which is in the shape of a figure eight. A fabric layer of substantial thickness is arranged around the rubber core, and a rubber tread is laid over the tread portion of the fabric. The vacuum space is also surrounded by a layer of fabric. To put the tire in running condition it is deflated by a pump, the influx of atmospheric air being prevented by a check valve. With the load of the car acting on the tires, the tendency is to compress the shape of the vacuum chamber. This tendency is counteracted by the exterior atmospheric pressure, resulting in a very elastic tire, according to its inventor and manufacturer. The partial vacuum in the tire tends to keep it cool.

Latest Smith Gasoline Meter

The Smith Gasoline Meter, 1789 Broadway, New York City, has redesigned its product, which is shown in Fig. 5. In the newer model, the indicator part of the meter is a brass cylinder over which slides a tape on which is printed the maximum number of gallons of gasoline contained by the tank, while the older model has an indicator finger moving over a circular dial printed in gallons. The construction of the meter is clearly illustrated in Fig. 5. It consists of a float F carried by the gasoline in the tank and held in the same vertical plane, at all times, by a brass rod R and a brass pipe P. A linen cord attached to the float is led through the pipes P, P1 and P 2 and its end is connected to that of the linen indicator tape which is held tight by the weight of a square brass column, 2 inches long, sliding in the square tube T. The float is made of 18-gauge brass and perforated at two places in its top and bottom, the holes being connected by short pipes soldered thereto, making the entire float perfectly tight. The float is made in two sections, an upper and a lower one, which are soldered together. The height of P and R varies with that of the gasoline tank and is so dimensioned that the pulley-containing connection comes within the space of the filler cap which holds the top of the rod and pipe in position while their lower ends are held in place by the plate P3 resting on the bottom of the tank. Tightness around the passage of the pipe P is insured by a lead packing placed between the tank bottom and the nut N screwed up against it.

The connection between the cord and tape is obtained by the use of the piece C1, which is of brass and bored with an axial passageway opening into one worked toward the opposite and along part of the length of the piece. A knot made in the cord is slipped through the second-mentioned passage, while the tape is drawn through the axial passage and a knot is used to keep it in place. The mechanism M, which consists of the brass cylinder and two spindles over which the tape slides, being kept in alignment, is simple and strong, and made of very few parts. This mechanism is inclosed in the indicator casing C2, the front of which is of beveled glass marked with a black line to give exact readings on the tape. The installation of the gasoline meter on the car and the correct marking of the tape are simple operations, and once installed, the device need never be worked with again as it is practically foolproof.

Special Automobile Wrench

In Fig. 3 is shown the special automobile wrench made by the Coes Wrench Company, Worcester, Mass. The tool is of the ordinary monkey-wrench design and works on the same principle of worm and nut engagement. The strength of the material and the proper shaping of its portions make it especially suitable for automobile use. One of the distinguishing features of this wrench is the strong, heavy, movable jaw. The gripping faces of the jars are plain, and a tight hold on the object may be obtained by this tool although there is no locking provision made in its construction.

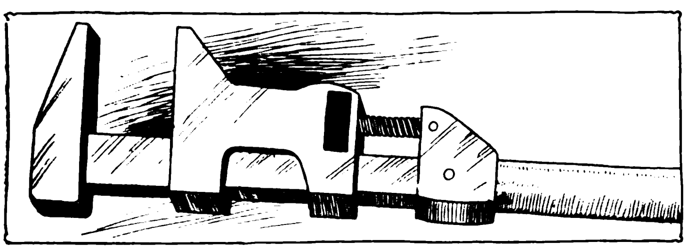

Fig. 3—Coes special automobile wrench, showing simple and substantial lines and very strong grip jaws

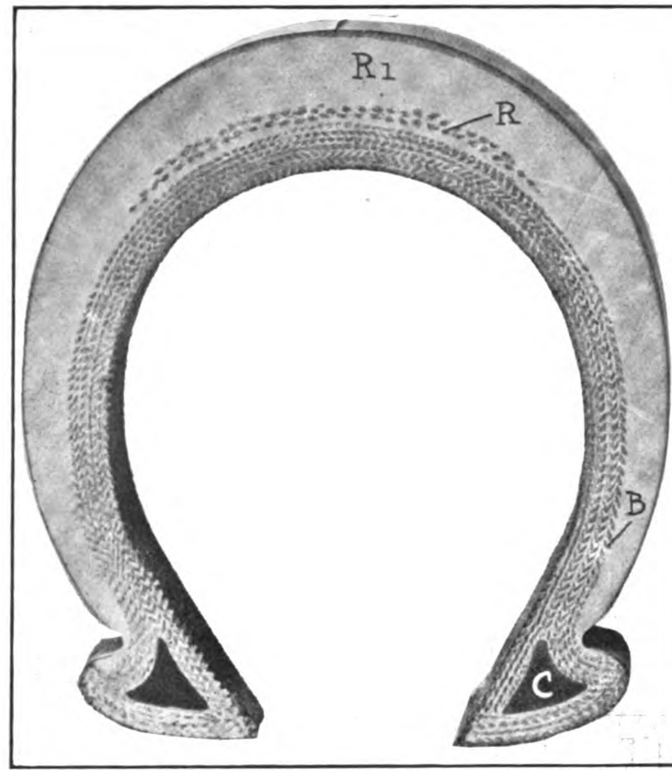

Fig. 4—Cross-section of Portage casing for light motor trucks

Portage Casings and Tubes

The Portage Rubber Company, Akron, Ohio, is the manufacturer of the casing which is shown in section in Fig. 4. The casing illustrated is designed for use on 1-ton trucks for fire-department work and similar purposes. The tread R_1 is built up on a cotton fabric of seven layers thoroughly frictioned together and strengthened at the tread side by a double reinforcement layer R. A single breaker strip B affords additional strength at the bead, where a cushion C of live rubber is enclosed in the vulcanized Para forming the tread material. The tubes manufactured by the company are of one of the best grades of up-river Para gum.

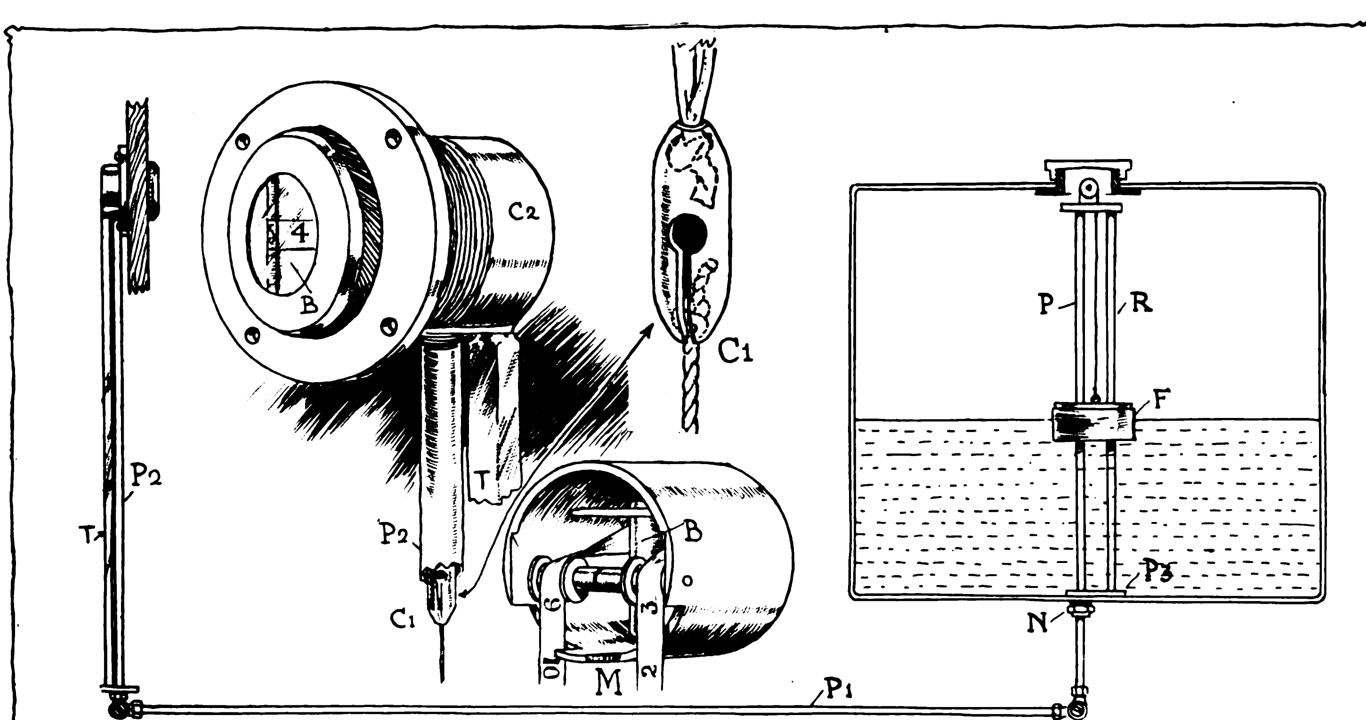

Fig. 5—Arrangement of the Smith gasoline meter, showing connections between tank and dashboard indicator and principal parts

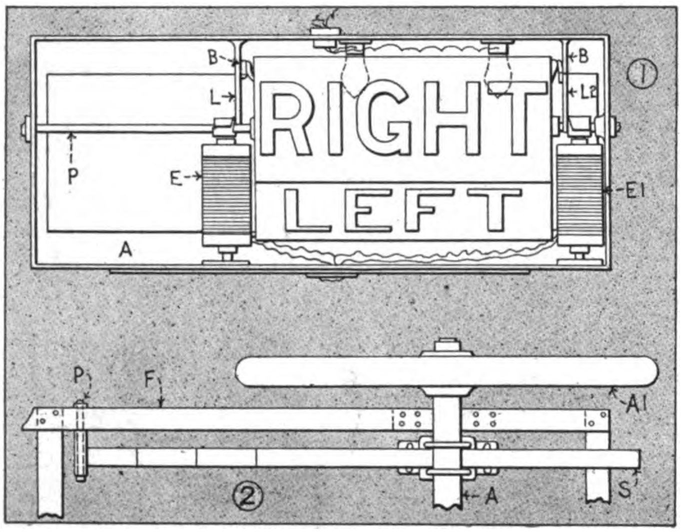

Fig. 1—Tail-light signal to be operated from the driver's seat
Fig. 2—Trott special circular vehicle spring suspension

VEHICLE Signal—A tail light indicator signal which is electromagnetically operated from the driver's seat.

This patent refers to an automobile rear signal, Fig. 1, consisting of a casing which contains electric lights L and a clear glass pane P in its rear wall. A rod R traverses the front of the casing, and two spaced brackets B are pivoted on the rod R, carrying a convex transparent sign arranged to be swung into a position behind the pane P. Another pair of brackets is pivoted on the rod between the other two; these brackets carry another sign which may also be swung in the same way. One of the signs bears the word Right, the other the word Left. At each of the signs an electromagnet E, E1 is arranged in the casing, each having an armature which is pivoted on the rod, lying over the respective magnet and has its rear end linked to a lever L, L1 fulcrumed above the armature. A link connection is provided between the forward ends of the two levers and one pair of brackets near their pivots. Electric circuits which are controlled by the driver excite the magnets and thereby regulate the relative positions of the signs.

No. 1,028,854—to Edward J. Best and Charles M. Fitch, Chicago, Ill. Granted June 11, 1912; filed December 27, 1910.

Vehicle Spring—A suspension type consisting of a circular spring fixed to a pivot and restrained in its movements by an alignment spring.

Fig. 2 shows the subject matter of this patent. A vehicle frame F is used in combination with a wheel axle A, a spring S being interposed between them and being pivotally connected at P with the frame. This spring is adapted to move circularly about its pivotal support. A non-supporting alignment spring is connected with the frame so that it resiliently opposes the circular movement of the first-mentioned spring.

No. 1,029,730—to Rolland S. Trott, Denver, Colo. Granted June 18, 1912; filed July 19, 1909.

Shock-Absorber—Comprising two sets of springs above and below the axle, which tend to hold the latter in position.

This type of shock-absorber, Fig. 3, requires the design of an axle with two forks F at its ends. To the ends of each fork a pair of horizontal cross-bars C is secured. An inverted U-shaped member A straddles each wheel, and the inner legs of these members extend through the above mentioned cross-bars to which they are rigidly connected. In the same plane as the cross-bar C of each fork end an upper and a lower cross-bar is arranged; the latter cross-bars being perforated to receive the outer legs of the member to which they are rigidly attached. On the inner leg of each member a sliding cross-head H is mounted, and another H1 on the outer leg of each arm. Springs are mounted on each leg of each member, being disposed between the opposite faces of the cross-heads and the cross-bars. A spindle for carrying the wheel has its ends secured to the cross-heads H and H1.

No. 1,031,381—to Herman H. Schmitt, Creswell, Ore. Granted July 2, 1912; filed March 4, 1912.

Windshield—Which is of the flexible type and may be moved to various positions.

This patent refers to a windshield, Fig. 4, which is so arranged that it may be made to slide on a curved rail disposed in the longitudinal plane of the automobile. The windshield is supported on the rail by means of an adjustable mechanism, and a slidable connection between shield and rail permits of clamping the windshield in position at desired points.

No. 1,031,020—to George F. Murphy, New Haven, Conn. Granted July 2, 1912; filed January 18, 1911.

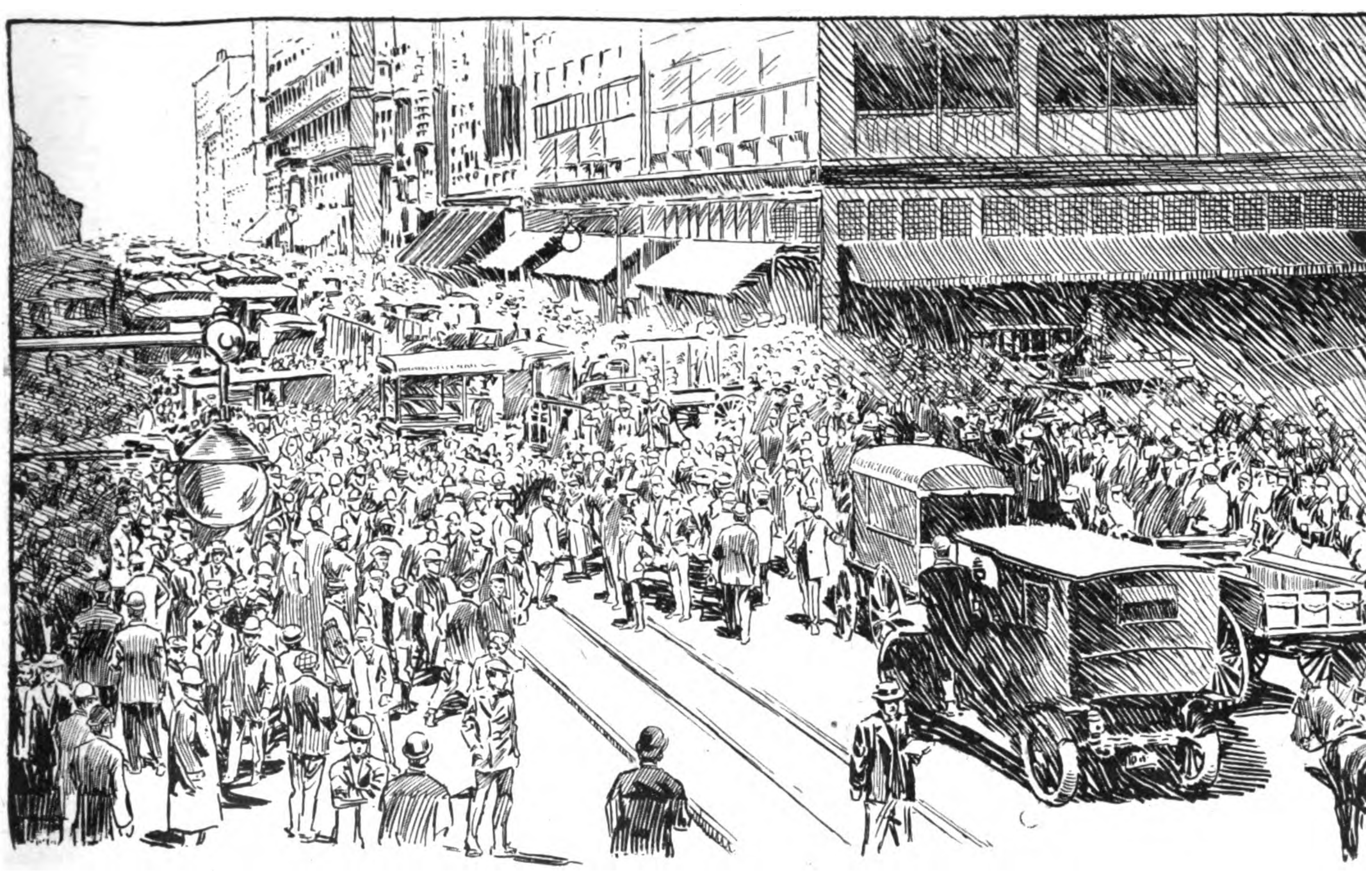
VOL. XXVII NEW YORK—THURSDAY, JULY 18, 1912—CHICAGO No. 3

THE AUTOMOBILE

New York Traffic Problem Serious

Police Insufficient in Number—Travel Must Be Diverted to Parallel Streets—Elimination of Horses Would Relieve Pressure—Pedestrians Must Be Controlled



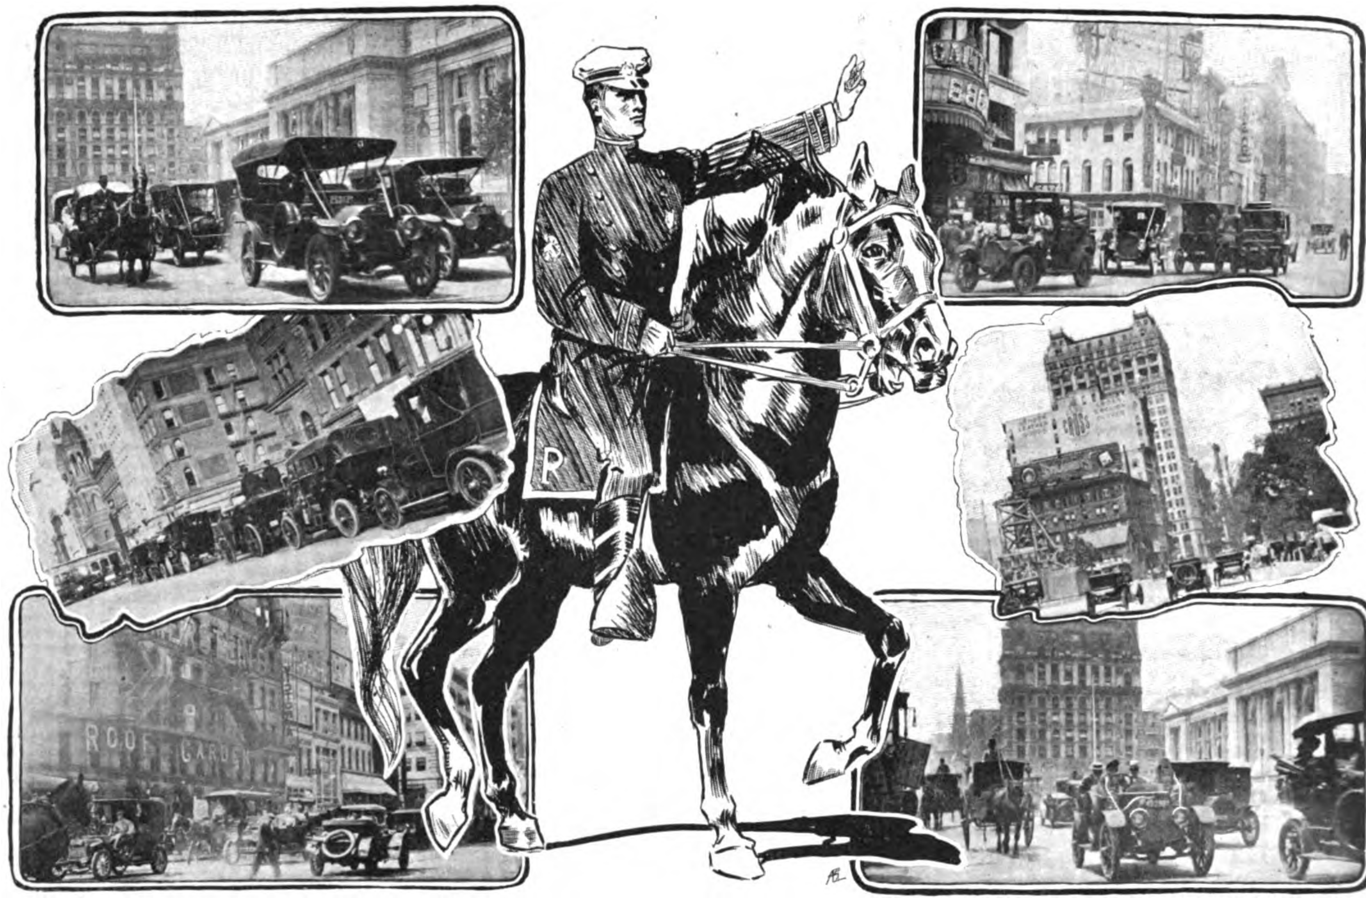
How metropolitan street traffic piles up when steady progress of vehicles is impeded for even a few minutes

EVEN when the horse shall be eliminated from urban traffic, as he bids fair to be within the measurable future, the problem of street congestion will be one of the most urgent puzzles to be solved by communities all over the world within the next 10 years.

Today New York has approximately 40,000 automobiles of one kind and another. In 10 years' time it is not at all unlikely that there will be 140,000, and many hopeful members of the automobile fraternity place the figures at 200,000.

Exclusive of motor buses and taxicabs, there are at the present time in daily use in carrying passengers in Greater New York on elevated and surface roads 8,836 vehicles. These transported during the past year the immense total of 1,617,182,963 passengers, a daily average, estimating Sundays and holidays as ordinary business days, of 4,430,638 passengers. While there is no means of accurately estimating the proportion of this traffic which eventually reaches the section south of Central Park, it is safe to say that half this immense total helps to form the human element in the problem which sooner or later must be solved if the preservation of life and the smooth transaction of business in the largest city of the western hemisphere be considered.

Of the total of 8,836 public passenger-carrying vehicles men-



Without this modern Centaur, the pedestrian's progress across New York's highways would be practically impossible. Some street scenes showing how vehicles accumulate during a 15-second stoppage

tioned above as constituting the rolling stock of the Greater New York transportation companies, no less than 5,150 run on tracks laid on the surface of the ground. Of these fully 75 per cent. navigate the section south of Central Park, and form of themselves one of the greatest factors in the problem of traffic management. During the past year these surface cars carried 834,024,416 passengers. In other words, each day there alight from surface cars in the metropolis 2,284,998 human beings who at once become important elements in the immense task imposed upon the city's guardians. The safeguarding of the proportion of this great throng that finds its way into that section of the city where the vehicular traffic has already brought about a condition of near-congestion is the task that confronts the police department of Greater New York at the present time. With the passage of the years these figures will increase in proportion with the increase in the number of automobiles, pleasure and business, and with the number of surface cars, if not with the number of horse-drawn vehicles, for it is the one fortunate phase of this situation that the number of horses to be found on the streets of the great city is gradually growing smaller with each succeeding year.

Daily Traffic Is Tremendous

One glance at the traffic that passes Fifth avenue and Forty-second street in any minute of the 10 hours from 10 o'clock in the morning until 8 o'clock at night is sufficient to show the major character of the problem that will be presented when there are twice, three or five times as many motor vehicles in service in New York as there are now.

Even in the heart of summer, when it is estimated that at least 30 per cent. of the local automobiles are not in use in town, the traffic is impressive during about 4 hours each day. Actual experiments with a stop-watch showed an average of fifty vehicles a minute moving over the crossing in both directions and for a while, between 3 and 4 o'clock in the afternoon, the average ran up to sixty-four cars a minute.

When the traffic policeman blows his whistle for the cars to halt either east and west, or north and south, a jam of automobiles results almost instantly. The cars pile up for a block back of the crossing in less time than it takes to tell it and at the same time the blocked cars in the transverse street move rapidly across the avenue, or street, as the case may be.

Ordinarily the way is left open across Fifth avenue for only 15 seconds at a time, while the north and south traffic is allowed to flow for 45 seconds during the most congested hours. A positive check on the Fifth avenue traffic for 2 minutes would serve to block traffic for a half mile and one such delay has often had the effect of choking vehicular movement for an hour.

Horses Complicate Situation

The elimination of horses would go far toward making the passage of the streets more comfortable and if such a result could be produced within a reasonable time, the chances are that the natural increase in automobile traffic would not reach the impossssible stage, even on the streets in use at the present time, until the number of cars in use touched the 100,000 mark.

But with the streets freed from the horse and with only the present facilities for handling automobiles, the advent of 100,000 cars would make for chaotic conditions.

In crossing Fifth avenue any afternoon when the shopping, business and theater-going public is abroad, it takes an alert mind and responsive muscles to keep out of trouble. Two robust traffic officers are stationed at the crossing. When the whistle is sounded for travel in a certain direction to stop, it stops, and with it pedestrians moving in that direction stop also, if they are wise.

When the signal is to stop the north and south movement, the street-cars, cabs, wagons and automobiles in the cross-street are motioned to come on. As far as vehicular traffic is concerned, such a signal is simple enough to understand and follow, but when it comes to the pedestrians, there is a different story to tell. The vehicles proceed along the right side of the street in the direction in which they are going, but the pedestrians move both ways on both sides of the street. This results in collisions and congestion and, while accidents are rare indeed where the police are stationed, any day's experience will show the potential possibilities. Often groups of pedestrians will dart from the sidewalk, passing in front of a halted file of automobiles just as the signal is given to move. If the street is crowded, they may be obliged to stand between two lines of rapidly moving cars, flanked by two lines of slower-moving vehicles, until the policeman signs for the procession to halt. There are several hours a day when it would be like inviting accident to attempt to cross Fifth avenue except when the traffic is halted.

The handling of this current of travel is admirably accomplished by the traffic squad. Policemen have never reached a higher expression of perfection than in this division of the New York force, and yet present facilities are close to their limit of usefulness and the influx of thousands of additional cars must mean more traffic policemen and a slower rate of travel.

Traffic Outgrowing Regulation

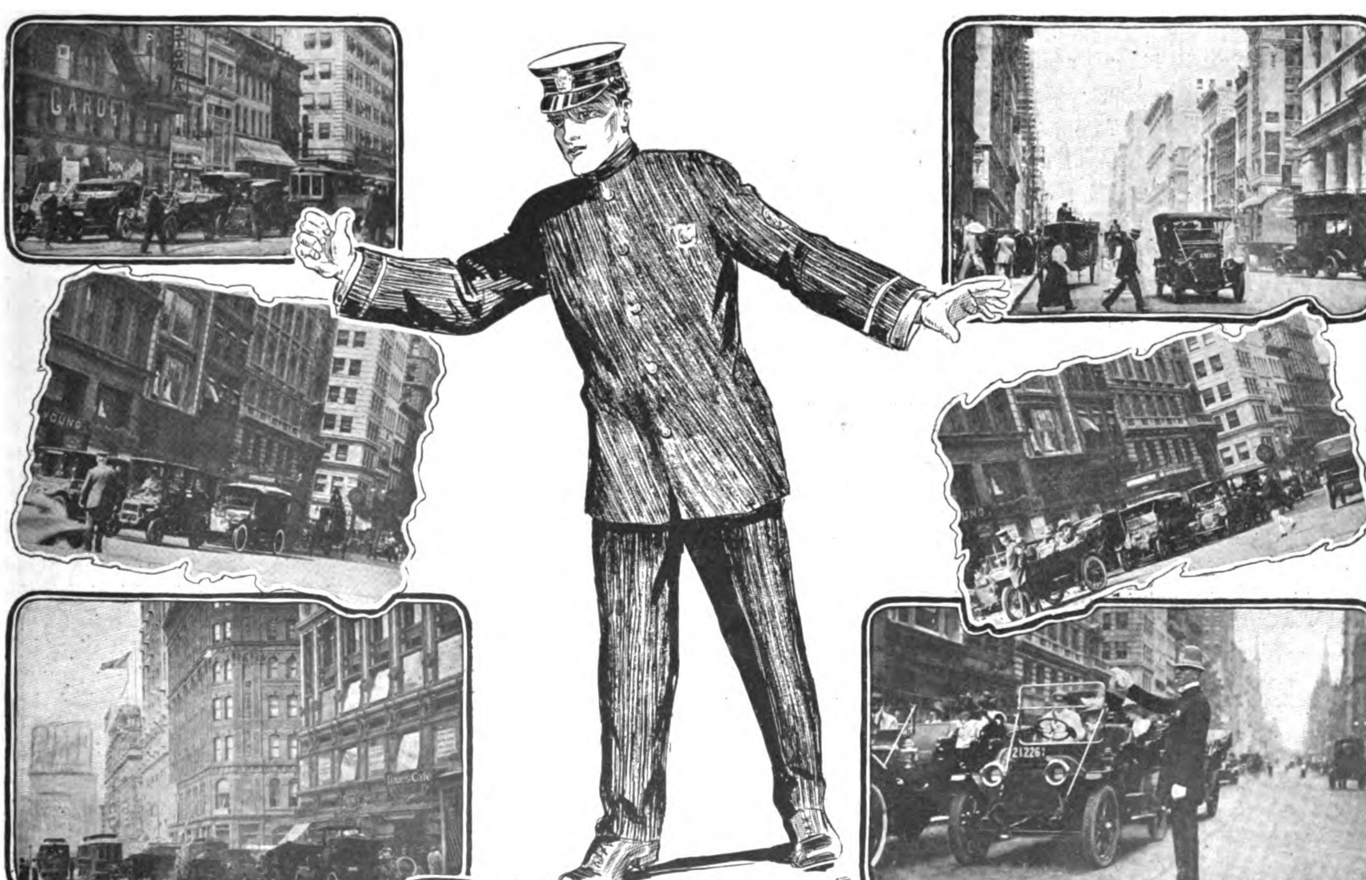
The traffic squad of Greater New York is made up of approximately 500 men, of whom 65 per cent. are assigned to duty in the business sections of the city during the day; but so rapid has been the growth of the traffic in these sections that it is fast outgrowing the means of properly taking care of it. True, a certain proportion of the regular police on fixed post assist in straightening out traffic tangles; but the rules require that they stick close to their stations, and in the event of a tie-up anywhere else but in their immediate neighborhood they are usually of but little assistance in relieving the congestion.

The solution of the difficulty is highly complex. In the first place, no matter what is done, the present courses of traffic are not sufficient to carry 100,000 automobiles. Therefore, the prime essential is the use of more streets to carry such a volume of traffic. The time will come when all the numbered avenues must be paved and maintained as Fifth avenue is today, or better. With fifteen main arteries to carry the flow of travel where three or four are used to any extent now, the physical necessities of the case would be ameliorated. Sixth avenue, with its elevated railroad pilllars and wicked pavements, could be arranged to relieve the situation by taking a portion of the business traffic and certain of the parked and boulevarded streets could be set aside exclusively for the passenger travel. There are enough avenues to carry ten times the present amount of traffic and the difficulty lies in the fact that everybody wants to use Fifth avenue, Park and Fourth avenues and Broadway.

Horses Handicap Automobiles

Second, while horse-traffic is decreasing, there are still a tremendous number of equine obstacles to progress in New York. If there were no horses there could be four lines of rapidly moving vehicles on some of the avenues instead of two rapid and two slow lines. It would be possible to move 100 vehicles a minute past a given point on Fifth avenue without endangering the lives of automobilists or pedestrians. At present, the extreme number of automobiles that can be thus handled is less than fifty a minute. In the figures given above, horse-drawn vehicles are reckoned in the totals.

Third, the experience of years has shown that, where the traffic is under the direction of the police, accidents are negligible in number. This, of course, does not take into account the reckless handling of automobiles contrary to law and against the orders of the police. It follows, therefore, that increased



The traffic officer must be the sole judge of the conditions at his particular crossing. He should be given unlimited sway in the direction of traffic and drivers and pedestrians alike should obey him

traffic must carry with it a need for more traffic officers. As these factors affect traffic they rank as placed: First, more streets; second, the elimination of the horse; third, more traffic police.

The details of caring for five times the present volume of vehicular traffic present problems that come properly within the province of the various municipal departments. It is only fair to say that each department in the city of New York is already overwhelmed with suggestions for meeting the exigencies of the case. Some of the suggestions display marvels of ingenuity and range all the way from subways for pedestrians, elevated platforms and other ideas based upon the desire for safety without reference to cost, to the most visionary dreams of unbalanced minds.

The first step toward solving the problem will be the enactment of a new motor vehicle law. Just what this should contain is a matter upon which almost everybody has some ideas, and most of them are divergent. It would seem that a provision should be inserted to give the traffic squad control of pedestrians as well as vehicles. All citizens have an equal right in the streets and the pedestrian has the right of way over the vehicle at the regular crossings. That being so, it would seem simply good judgment on the part of the pedestrian to move only when the police guardian of the crossing deems it safe for such procedure. The policeman, knowing that the pedestrian has the right of way, cannot arbitrarily hold him longer than his safety seems to require.

Conditions Same in Other Cities

The experience of other American cities is very similar to New York's. In Chicago, where, from the topography of the city, there is not such a prospect of congestion in the outlying districts, the loop section is almost as badly crowded and the stream of traffic requires very strenuous efforts on the part of the police to keep it flowing. In Philadelphia the situation is somewhat better, owing to the way the city is spread out between the rivers. But in all of them the problem of handling vehicular traffic will become acute sooner or later and, for that reason, the eyes of the country are upon New York and Chicago, particularly the former, to learn how the big towns will go about the solution.

In London, where the horse has all but disappeared from the more congested sections, 400 persons were killed and 10,000 persons were hit by vehicles during 1911.

Crossing from the south side of the Strand to Cockspur street the pedestrian has to avoid eight files of fast moving vehicles, four lines moving in each direction. The city of London is now at work upon the idea of a traffic board, which has been recommended to consider the matter of vehicular traffic by a royal commission.

According to the conclusions of the British investigators of the subject, there is nothing that can be done to check automobile traffic, because it represents the highest stage to which the art of transportation has been developed. Therefore, the energies of the Britons will be directed toward regulating and diverting traffic from certain streets so as to avoid congested conditions.

An idea of the volume of New York traffic may be gained from a consideration of the following facts:

Average number of automobiles that pass Forty-second street on Fifth avenue each day is 11,432.

Average number in summer between 3 and 4 o'clock in the afternoon, 2,940. In winter, the rush hour sees about 3,500.

These figures do not represent as many cars as they seem to, because, in many cases, the same car passes twice or more during the illustrated period.

Lord Montagu, editor of *The Car*, during his recent visit to New York, remarked that, in his opinion, "the solution of New York's transportation problem is the omnibus. With this type of vehicle," he stated, "the driver has more freedom to wind in and out of the traffic and is not compelled to remain on one set of tracks."

The claim was also advanced that the city policeman was an important factor in the situation and this proved the subject of an intensely interesting address by Chief Justice McAdoo, who made comparisons between the city policeman of London and New York. In considering the former, he stated that, in London, "every traffic policeman is an inspector of vehicles. He has the power to order off the streets any car which is undesirable on account of its appearance, or by reason of any doubt as to its safety. Any car that is ordered off the streets cannot get back until it has passed through a special examination."

Lord Montagu also expressed considerable surprise that any one owning a car could drive the same about the streets of the city without first passing an examination establishing his competence as an operator.

With regard to the suggestion of Lord Montagu as to the effect of buses on New York traffic congestion, it may be said that there are over 2,000 motor-buses in use in London and it is contemplated to increase the total to 4,500 next year. It is interesting to note that of the 400 fatalities due to automobile accidents in London last year, 107 were the results of motor-bus accidents.

Hence, it might be reasoned that buses as operated in the British capital might not be the answer to the puzzle from the viewpoint of the pedestrian.

During the year beginning with July 1, 1911, and ending with June 30, 1912, the traffic casualties in New York were as follows:

Killed by automobiles	190	
Injured by automobiles		1,268
Killed by street cars	119	
Injured by street cars		851
Killed by wagons	165	
Injured by wagons		303
Total killed	474	
Total injured		2,422
Total casualties		2,896

Practically all of these mishaps occurred where there were no traffic officers on duty. In the item covering injured by wagons, the number is undoubtedly less than the actual number and the street car mishaps where the pedestrian was at fault and the injuries trifling is understated.

The showing is measurably worse than that of London, where there is a vastly larger population and congestion.

The National Highways Protective Association is working for uniform laws covering traffic in all the main centers in the United States.

Automobile as Naval Adjunct

Los Angeles, Cal., July 13—The fact that the automobile is really practicable for the use of landing parties was forcibly demonstrated recently when Lieutenant-Commander A. H. Woodbine of the Seventh and Eighth Divisions, Naval Militia of California, took a full gun crew of thirty-three officers and enlisted men, a one-pounder weighing 800 pounds and three drivers to Pasadena in three Oldsmobile cars furnished for the test by Captain Ryus of Los Angeles.

The cars used were the three leading types of the Oldsmobile line. Captain Ryus drove the Limited, in which the commanding officer rode with the gun and gunners; Ensign Linck had the Autocrat in which the caisson was carried, with ten members of the crew, and the Defender was in command of Ensign Smith. In this car, the smallest of the trio, thirteen men rode, and it kept its position right behind the big Limited, which played the part of the flagship.

The gasoline fleet covered the distance from Los Angeles to Pasadena armory in 21 minutes. The gun, which was mounted on the tonneau of the Limited, rode perfectly, and it was not necessary for the gunners to give it any attention whatever on the way.

Legal News of the Week

Receiver Authorized to Sell Atlas Engine Works on July 29—President Hanna Protests

Suit Over Taxicab Company Names—Motor Cabbies Fined for Maintaining Nuisance

INDIANAPOLIS, IND., July 15—Judge Clarence E. Weir, of the superior court, has authorized Fred C. Gardner, receiver for the Atlas Engine Works, to sell the company's property and has fixed July 29 as the date of sale. The only bidder in sight at this time, is a motor car concern in Detroit.

The date of sale was fixed over the protest of Hugh H. Hanna, Sr., president of the company, who owns all of the common stock, some of the preferred stock and who is also indorser on $1,100,000 in notes of the company given 5 years ago, when a creditors' committee took charge of the plant. Mr. Hanna, through his attorneys, contended the sale should not take place for at least 60 days, in order to permit proper advertising in trade journals and to enable him to have an opportunity to undertake to finance a bid on the property himself.

Attorneys for the receiver, however, opposed Mr. Hanna's suggestion. They contended if the sale were delayed or not made to the prospective purchaser in sight the bondholders would not receive 50 cents on the dollar and other creditors of the company would lose everything.

In the proposed terms of sale, which have been agreed to by the receiver and the prospective purchaser, the common stock, preferred stock and the $1,100,000 notes indorsed by Mr. Hanna will be eliminated and nothing paid on them. The stocks and securities of the company have not been listed for several years, but a manual issued in 1906 states that the authorized common stock was $1,000,000 with $750,000 issued and the preferred stock bearing 6 per cent. interest, $1,000,000, all of which was issued. The undivided profits in 1904 were $60,969.95 and in 1905 the undivided profits were $66,343.44.

The prospective purchaser proposes to assume a mortgage against the property securing bonds amounting to $1,050,000, to pay $105,000 indebtedness incurred in a bond issue of $150,000 and turn over enough cash to the receiver to pay all mercantile accounts contracted since a creditors' committee took charge, as well as the salary rolls and receivership expenses, amounting to about $80,000, which has been fixed as the upset price. The purchaser is to cancel the bonds.

It is said the proposed purchaser, if it gets the property, may not continue the manufacture of Silent Knight motors or crude oil engines, but will make a line of four-cylinder cars selling at from $1,200 to $1,500.

Decision Soon in Klaxon vs. Waite

PROVIDENCE, R. I., July 13—Judge Brown, of the United States district court, who heard the case brought against the Waite Auto Supply Company for an injunction on behalf of the Lovell-McConnell Manufacturing Company, the Hutchinson Electric Horn Company and the Miller-Reese-Hutchinson Company to restrain the former company from selling the Klaxon and Klaxonet horns, has taken the case under advisement and will render a decision shortly.

Taxicab Companies' Names Confuse

BOSTON, MASS., July 13—Franklin T. M. Hammond, who was appointed master in the suit brought by the Taxi Motor Cab Company, of Boston, against the Motor Cab Company, of Boston, for an injunction to restrain the latter company from using that name has filed his report with the Supreme Court of Massachusetts and a decision is expected shortly. The Taxi Motor Cab Company operates about fifty vehicles with taximeters, and has its headquarters at 541 Tremont street, South End. The Motor Cab Company operates its cabs without taximeters, basing the fares on the hackney cab rates, and its headquarters are the Hotel Somerset, Back Bay. Neither company has its name on its cabs to tell them apart, and the plaintiff claims the similarity of names brings confusion. The master in his report says the ordinary traveler is ignorant of the fact in which company's cab he is riding and that confusion results and the name of the defendant will be likely to be mistaken for that of the plaintiff. An injunction may be granted therefore.

Motor Jehus Fined as Nuisances

PHILADELPHIA, July 15—That automobiles bearing "to hire" signs standing on certain of the principal thoroughfares in the central section of the city are an obstruction to traffic and a nuisance, is the gist of a decision rendered recently by Magistrate MacFarland in the Central Court, who held two chauffeurs under $200 bail each for court for permitting their machines to stand in front of the Bingham Hotel after being warned not to do so. On the part of the accused it was contended that discrimination was practiced by the police in ordering some cars away while not molesting others, but in the case of the latter it was claimed by the police that they held permits. As no permits are issued, Magistrate MacFarland said that all chauffeurs similarly charged with obstructing the highways were to be arrested.

Broke Law in Setting Speed Trap

BUFFALO, N. Y., July 15—Because they failed to file with Secretary of State Lazansky a notice of their intention to create an ordinance governing the speed of motor vehicles and because the state law prohibits enforcement of ordinances in cities other than those of the first class restricting speed of motor vehicles to less than 15 miles an hour, the Salamanca, N. Y., police department violated the law when they arrested motorists who were driving 12 miles an hour and fined them various sums. At the trial of the motorists, it developed that the Salamanca police placed the speed trap in operation so that a deficit in the Salamanca department could be offset.

A NUMBER of new licenses have been issued by Dyer, Dyer & Taylor to automobile owners in New York and the metropolitan district. About half of these licenses cover imported cars, while the remainder is made up largely of Sultan automobiles. The list of licenses and the cars owned by them is as follows:

Alexander Krull, Queen; William A. Delano, Lancia; John H. Cooper, Lancia; Michael J. Bird, Sultan; Ludwig Kraus, Darracq; James Bernshaw, Darracq; Thomas Callahan, Sultan; Washington Garage Company, Sultan; David Rumsey, Lancia; Alwin Young, Sultan; Adolph S. Berquist, Rochet-Schneider; Joseph G. Fornecker, Sultan; David H. Gaines, Zust; L. H. Cuneo, Itala; J. Applegate & Company, Cortlandt; C. F. Welch, Cleveland; John H. Meyer, Isotta; Joseph Lacherque, Sultan; John H. Bowers, Sultan; J. F. Pierson, Jr., S. P. O.; Peter Pavlovich, Charron; John A. Camera, Sultan; Hector Califfe, Sultan; Frank J. Tampone, Sultan; Dr. George H. Smith, Cleveland; John Kostukevich, Sultan.

C. A. Glentworth, the New York agent for Napier cars, has paid Dyer, Dyer & Taylor damages for infringement in acknowledgment of the basic Dyer patents.

DAYTON, O., July 15—Entry of settlement and dismissal was filed in the common pleas court in the action brought by Bert Shroyer against the Peckham Motor Car Company for $1,800. The $390.30 suit brought against the same concern by the Michelin Tire Company was also settled up and dismissed.

Board of Trade Meeting

New York Show Will Open in Two Buildings on Night of January 11, 1913—Republic Plans

Big Dividends by Canadian Ford and Reo Companies—Amplex Company to Start on August 1

THE Automobile Board of Trade at its quarterly gathering in New York City Thursday listened to the report of the Show Committee, covering plans for the big exhibition of next January, which will be conducted in two buildings, the new Grand Central Palace and the Madison Square Garden, with a single admission covering both buildings.

It was definitely decided to open the show on the evening of January 11, 1913, with an exhibition of pleasure cars in both buildings, continuing until the 18th. The commercial vehicle division, which will be held in both buildings, will open on the evening of Monday, January 20, closing on Saturday evening, January 25.

Suitable resolutions were passed on the death of Mr. Alfred N. Mayo, of the Knox Automobile Company, one of the oldest members of the Automobile Board of Trade and a leader in the industry since its inception.

It was also voted to begin compilation of data for the publication of the 1913 handbook.

Among the companies represented at the meeting were the Autocar, Buick, Cadillac, Cartercar, Chalmers, Cunningham, Elmore, Franklin, Garford, Haynes, Hudson, Knox, Lozier, Marquette, Matheson, Mercer, Metzger, Mitchell, Moline, Moon, Marmon, National, Oakland, Olds, Packard, Peerless, Pierce-Arrow, Pope, Premier, Pullman, Rapid, Reliance, Stearns, Thomas, White, United States Motors, Overland and Winton.

Amplex to Resume on August 1

MISHAWAKA, IND., July 13—Operations at the plant of Amplex Motor Car Company, which recently underwent reorganization, will begin about August 1. W. J. Mead, president of the concern, announces that the daily output of the company will be five cars. It is the intention to employ between 750 and 1,000 men. Mr. Mead will soon take up his residence in Mishawaka. E. C. Wetten, the secretary of the company, is a Chicago attorney. Considerable interest attaches to the announcement that the two-cycle cars which the concern has been making will be discontinued. A six-cylinder, long-stroke, pocket-valve car of standard design is planned and a Knight type motor machine to be made in limited quantities. There will be no change in the Amplex chassis.

Locomobile Increases Capital Stock

BRIDGEPORT, CONN., July 16—In order to take care of real estate deals involved by the building of several large service buildings in some of the leading cities, especially New York, Chicago and Philadelphia, the Locomobile Company of America has increased its capitalization from $5,000,000 to $6,500,000.

Republic Motor Announces Its Plans

The Republic Motor Company of New York expects to be in full possession of its new headquarters at Eleventh avenue and Fifty-seventh street in 90 days. It has been learned that it intends to build two styles of car, a four-cylinder light type to be sold at $715 and a six-cylinder five-passenger touring car to be sold at $1,000.

W. C. Durant, president of the company, stated that it is the belief of the concern that further economy in the automobile industry will not be in the manufacture of the car, but in its distribution. The Republic Motor Company is designed especially to secure greater economy in the distribution and to go still further in selling in each locality a car which is adapted especially to that vicinity. He stated that it was necessary for a car that was designed to meet all sorts of service to be a compromise, as a car designed for flat country would be under extreme disadvantages in hilly country. This condition is to be met by the establishment of ten factories in the largest distributing centers.

The parent company is the Republic Motor Company of Delaware which has been incorporated for $65,000,000, the stock being divided into $15,000,000 of 7 per cent. cumulative preferred and $50,000,000 common. The ten operating companies are each incorporated at $1,500,000. They all have the name of the Republic Motor Company and are located in New York, Boston, Philadelphia, Chicago, St Louis, Kansas City, Minneapolis, Portland, O., Los Angeles and San Francisco. The Little Motor Car Company, of Flint, Mich., and the Chevrolet Motor Car Company, of Detroit, will, it is said, form a part of the Republic combination.

Companies Declare Big Dividends

WINDSOR, ONT., July 13—The Ford Motor Company, of Walkerville, has declared a dividend of 20 per cent. on the new issue of stock. The original capital was $125,000, on which annual dividends were paid of 100 per cent. Then capital was increased to $1,000,000, of which $750,000 was paid up. On this

Automobile Securities Quotations

A downward trend characterized the week's stock market of automobile securities. Comparison of the table given below with the quotations of last week show that where changes occurred they were almost invariably in the nature of decreases. The tire stocks, which rallied last week on the ground of a possible consolidation of a number of independent tire makers, declined when these reports were officially denied. Goodyear held an exceptional position, proving strong and being the center of considerable activity. Firestone also scored a respectable advance. Among the automobile manufacturing securities Packard and Studebaker preferred stood almost alone with fractional rises, while the other stocks in this department either remained unchanged or declined.

amount dividend checks of 20 per cent. are being paid for the first half year, which amounts to about 120 per cent. on the original stock.

LANSING, MICH., July 15—The Reo Motor Car Company has declared another dividend of 10 per cent. and about $200,000 in cash will be distributed. A few weeks ago a 10 per cent. dividend was declared, making a total profit of $400,000 the stockholders have received this year. Nearly 75 per cent. of the dividends goes to Lansing residents. At the present time the plant is being run at full capacity, a car being turned out every 11 minutes. Two thousand men are employed, but the company is unable to keep up to the rush of orders.

How Canadians Attract Industries

BERLIN, ONT., July 15—After the officials of the Canadian Consolidated Rubber Company, makers of rubber tires for automobiles, expend $250,000 in building and equipment of their factory in this city, they will be awarded a bonus of $25,000 which has been raised by local property owners, and a fixed assessment for that amount for 10 years. This rubber concern, which already has large interests here, will purchase fifteen additional acres of land on which they will construct two mammoth tire factories. During the first year 100 skilled workmen will be employed at this plant, 200 the second and 500 in 5 years hence. That was an agreement reached before the bonus was awarded. Hamilton, Ont., tried hard to land this industry, which is considered the largest industrial proposition in the history of Berlin.

Market Changes for the Week

Businesss in the metal market was limited last week, and quotations declined slightly in the case of lead and more noticeably in that of tin. Copper and steel remained practically unchanged. Characteristic of the condition in the metal market is a general downward trend of the products of other than the iron and steel industry, while the demand for the products of the latter has fallen off when compared to what it was 2 or 3 weeks ago.

One of the most important developments of the week was the 3-cent rise in Para rubber which took place on Friday last. Fine Up-river sells now for $1.15 a pound, and, while the activity of the rubber market is none too intense, the general tone is strong. A feeling of restriction noticed about a week ago was due to a vague apprehension that artificial rubber could possibly develop, in the near future, as a serious competitor of the natural product. The week's changes follow:

No Tire Merger Probable

Firestone and Goodyear Officials Say That Rumors Are Without the Slightest Foundation

Keeton Will Confine Its Energies to Six-Cylinder Cars—Will Brown to Head New Truck Company

AKRON, O., July 16—Publicity has been given during the week to reports tending to show that another big consolidation of rubber plants here is about to take place. The two firms mentioned are those of the Firestone Tire & Rubber Company and the Goodyear Tire & Rubber Company. It has been claimed that the same parties who worked out the Goodrich-Diamond merger are working out plans for the next two largest plants here. No sooner had the rumors appeared in print than vigorous denials were made by H. S. Firestone, president of the Firestone Company, and F. A. Seiberling, president of the Goodyear Company.

"There is absolutely no truth in these reports of consolidation," said Mr. Firestone. "The Firestone Tire & Rubber Company will not sell out to, consolidate with or absorb any other rubber company. The Firestone Company has sufficient capital stock and real cash to run the business, and there is no stock or cash consideration which will change that policy."

"There is not the slightest foundation for these rumors," says F. A. Seiberling, president of the Goodyear Company, "and if I understand the temper of the management, there is not the remotest possibility of the Goodyear being absorbed by any of them, and I am equally certain that there is no thought of its becoming an absorber."

Keeton Will Not Build Fours

WYANDOTTE, MICH., July 13—The Keeton Motor Company has purchased the plant formerly owned by the Seitz Automobile & Transmission Company, where the manufacture of a six-cylinder car will be begun immediately, the company having abandoned its original intention of making both fours and sixes. The six will have the same construction and body details as already announced, with the exception that the motor will have a stroke of 5 1-2 inches, this being 1-4-inch longer than that originally planned. The bore remains at 3 3-4 inches. The motor will be a special design and will be made for the company by the Wisconsin Motor Manufacturing Company, Milwaukee, Wis., at which plant R. P. Brown, engineer of the Keeton Company, has spent the last 6 weeks in directing the preliminary steps in its manufacture.

Brown Forms New Truck Company

PERU, IND., July 16—The Brown Commercial Car Company has been organized by Will H. Brown, who has interested several prominent local bankers and business men in the enterprise. Mr. Brown has been elected president and Carl H. Wallerich vice-president. The new company will occupy the plant formerly used by the Otis Elevator Company, a finely equipped structure, sufficiently large and up-to-date in every respect.

A light delivery car which has been developed during the past year will be manufactured to sell at about $1,600.

Will H. Brown is president and general manager of the Mais Motor Car Company, Indianapolis, which makes the Mais truck. He will continue his duties with the latter company, at the same time devoting considerable attention to the new enterprise. Carl H. Wallerich until recently has been manager of the General Industrial & Manufacturing Company, Indianapolis, from which he has resigned to enter the new company.

The Indiana Four-States Tour stopped for a breather at Findlay, Ohio, where the inhabitants turned out in force

Four-States Tour Success

Fifteen Indiana Automobile-Making Concerns Represented—Business Results Already Apparent

Affair Has Been Advertised Ahead and Prospective Buyers Are Rounded Up to Inspect Cars

CANTON, O., July 14—Indiana automobile manufacturers are now on their second annual Four-States Tour. They have crossed the northeastern section of Hoosierdom, have invaded Ohio, and are now preparing to bend southwestward toward West Virginia. As a fitting climax to a successful first lap of their journey the entire Indiana motoring party this afternoon placed in the imposing mausoleum of William McKinley a beautiful floral set piece as a token of their esteem of one of Ohio's most beloved sons.

It is with the intention of investigating automobile trade conditions and arousing general enthusiasm that this tour is covering nearly 1,300 miles of road in the states of Ohio, West Virginia, Kentucky and Indiana. With twenty-eight cars in the party, including four commercial vehicles, the tourists left Indianapolis on Tuesday morning, July 9, and ran to Fort Wayne, making stops in Kokomo, Peru, Wabash and Huntington. On Wednesday they journed to Lima, O., and on Thursday to Tiffin, stopping en route at Findlay, Fostoria and Fremont. To the home of the rubber industry they ran on Friday and this afternoon a short journey brought them to this city.

Tire Town Gave Famous Welcome

Akron will always be famous in the memory of those making this trip. The rubber industry entertained as royally as is its wont and there was one continuous round of festivity from the time the cavalcade reached Barberton on Friday afternoon until it bid goodbye to Akron this afternoon.

Saturday morning was given over to the inspection of seven of the tire factories—Diamond, Firestone, Goodrich, Goodyear, Kelley-Springfield, Motz and Swinehart, the concerns which entertained the Indiana visitors.

Trade conditions along the route are apparently in a splendidly prosperous state. They depend largely upon agricultural prospects and with the close approach of the actual harvest season automobile dealers are most sanguine of a continuance of the present healthy buying demand. In every town visited the motor car representatives give interesting accounts of the amount of business being done. The low-priced cars are in the lead in numbers; the second-hand problem is not as serious as in the big cities; and the size and trade of the garages indicate the stability of motor car affairs along the 450 miles traversed.

The dealers are looking forward to closing their 1913 contracts and the majority of them expect to continue the lines which they are at present handling. Naturally their interest in the Indiana-made products has been much increased during the last few days.

Northeastern Indiana and the northern tier of Ohio counties cannot boast of pleasant road conditions. To the limit of the Hoosier state hard pikes were covered, but their surfaces were not as even as could be desired. For 3 days the dirt roads of Ohio have had a great cloud of dust raised from their rough and corrugated faces. For a few miles on either side of Akron brick roads have been experienced, and these have been really the only good roads covered by the cars.

Fifteen Companies Represented

Fifteen automobile makers and one of an accessory are participating in this event. They are: American Motors Company, Cole Motor Car Company, De Tamble Motors Company, Great Western Automobile Company, Haynes Automobile Company, Lexington Motor Car Company, McFarlan Motor Car Company, Marion Motor Car Company, Nordyke & Marmon, Maxwell-Briscoe Motor Company, Motor Car Manufacturing Company, Nyberg Auto Works, Premier Motor Manufacturing Company, Service Motor Truck Company, Whitesides Commercial Car Company and the Double Fabric Tire Company of Auburn.

These companies represent the cream of the Indiana producers and they have entered upon this method of showing their latest models with the zest and thoroughness for which they are famous. They have circularized the dealers along the entire route, have used advertising space in the daily newspapers and have posted large lithographic sheets to herald their coming; and have made arrangements which are bringing forth actual results in business for them. They have made the daily runs purposely short and have scheduled stops in all important towns in order to show to the trade and to the public 1913 models.

The American Motors Company has gone to the extent of corresponding with every prospective purchaser within 50 miles of the line of march, inviting them to come to the route. Maxwell dealers along the way and for a large distance on either side have been supplied with Maxwell pennants and information regarding the tour, and Maxwell owners have been seen in great numbers at the crossroads and in the towns.

The personnel of the party is composed mainly of sales and advertising department men. At each stop the former have the opportunity to call on the dealers while the latter generally form a line toward the newspaper offices. The cars themselves include a number of famous and particularly interesting features. The two De Tamble cars are equipped with rotary-valve motors. One of the Haynes cars is the last of the 1912 series, and is the machine which was assembled in less than 2 hours during the convention of Haynes dealers recently. The Maxwell carrying the number 3 is the one which carried the same numeral when it won the 1911 Glidden tour. The Premier Schooner is the same car which made the Overland trip from Atlantic City to Los Angeles last year, and now is acting as an emergency ambulance. The Nyberg truck carries a pipe organ, the Whitesides truck a piano, and the 6-60 Premier and the Pathfinder touring car each have ten-tone Gabriel horns—furnishing ample music for the party.

The Great Western is the confetti car, the pacemaker is drawn for each night, the Marion is the checker's car, the chairman rides in an American and a Lexington carries the secretary's flag. A Nyberg car preceded the tour one week, putting out handbills, posters and distributing advertising matter.

Redwood Falls Sociability Tour

REDWOOD FALLS, MINN., July 16—The second annual sociability tour of the Redwood Falls Automobile Club started in a driving rain at 6 a.m. July 12, with twenty-one cars in line. George Jaehning drove a Cadillac as a pilot car and Rud Stensvad a Cadillac as a pacemaker. There were six Cadillac cars in the tour, three E-M-F cars, four Mitchells, a Cole car, KisselKar, Imperial, Locomobile and a Chalmers.

The first day's run was through southern Minnesota to Waseca for the night control. Short stops were made at New Ulm, Janesville, Waseca, New Richland and Albert Lea. Mankato was the noon stop, where the tourists were addressed by William Jennings Bryan. At each stop automobiles were picked up as escort to the next large city. Gumbo roads and several side slips resulted in the change of night control 60 miles from Austin. That city became the noon control the second day. The night control at the Hotel Radisson was reached long after dark, and the tourists put up for a rest all day Sunday. The time was spent at the Bloomington Country Club and touring the city. The last day's run was by way of Lake Minnetonka and along the Minneapolis & St. Louis road to Redwood Falls.

Farmers and Ranchmen's Tour

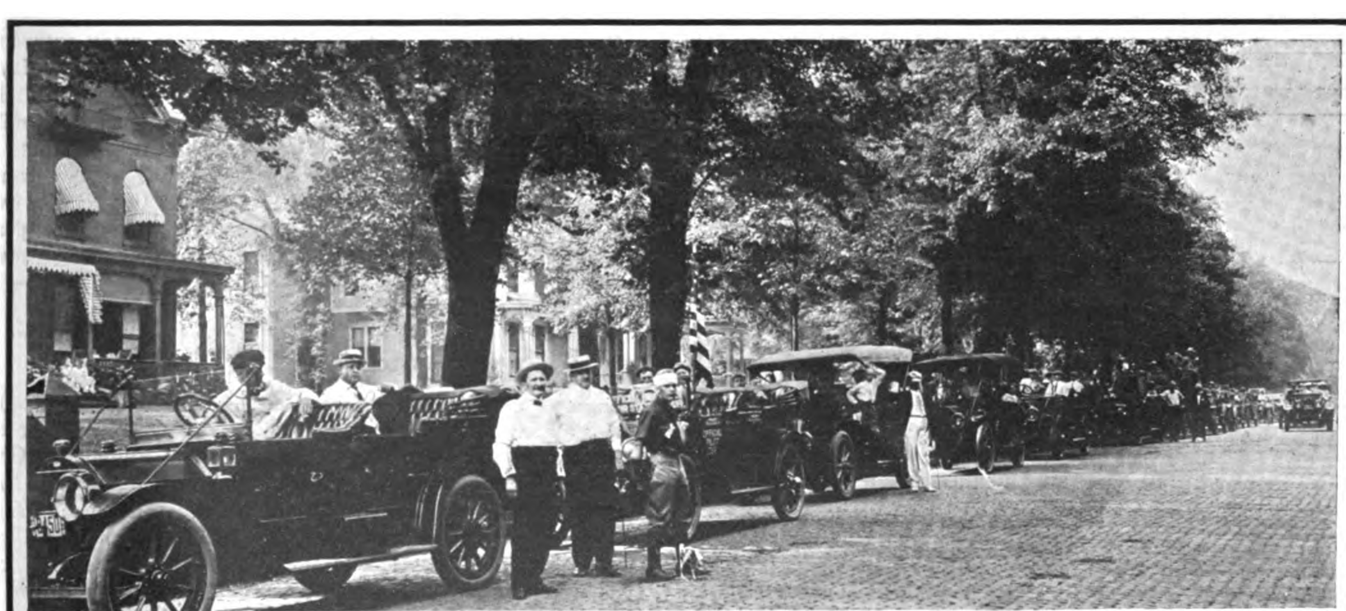
DALLAS, TEX., July 13—Everything possible for the success of the Farmers and Ranchmen's tour from Dallas to San Antonio, July 22-27, has been done. Entries close July 17. Sixty automobiles will leave Dallas on the morning of July 22 and will endeavor to tour to San Antonio and return. Each car must carry four passengers and must be driven by the owner of the car, said owner to be a farmer or a ranchman.

Leaving Dallas the official route is as follows: Lancaster, Red Oak, Italy, Hillsboro, West, Waco (night control), McGregor, Moody, Pendleton, Temple, Holland, Bartlett, Granger, Georgetown, Austin (night control), Buda, Kyle, San Marcos, Godwyn, New Braunfells and San Antonio. Return trip: New Braunfells, San Marcos, Austin, Taylor, Rockdale, Cameron, Ben Arnold, Rosebud, Lott, Marlin, Groesbeck, Doyle, Mexia (night control), Wortham, Richland, Corsicana, Rice, Ennis, Garrett, Palmer, Trumbell, Wilmer and Dallas.

Cleveland Reliability Abandoned

CLEVELAND, O., July 15—Announcement was made late Friday afternoon that the run to be conducted by the Cleveland *News* would not be held July 15 to 18 as planned. The abandonment of the tour was due to the fact that the event this year would not have the broad character of previous years, and would, therefore, fail to meet the prime purpose of the undertaking. While the entries were exceptionally generous variety of make was lacking, and in that variety lay the chief public interest in the event.

WASHINGTON, D. C., July 14—So successful was the sociability run of the Automobile Club of Washington, held several weeks ago, that the club is planning to promote another contest along the same lines. A different route will be laid out and efforts will be made to secure the entry of more than 100 machines. It is likely President Taft will be asked to set the secret time in which the run will be made.



The Four-Staters halted at Canton, Ohio, in front of the former home of William McKinley, the martyred President

C.A.C. Gets Elgin Meet

Aurora and Illinois Trophy Races Set for August 30—Elgin and Free-for-All to Be Run Off Next Day

Course Already in Fine Shape, and Numerous Entries Promised—Prize List More Than Doubled

CHICAGO, July 13—The annual road races at Elgin, Ill., will be continued after all, the Chicago Automobile Club having taken the place of the Chicago Motor Club as promoter, the alliance with the Elgin Automobile Road Race Association being completed this week. Following the closing of the deal, there was a change in dates, the races being billed for August 30-31 instead of August 23-24, which had been selected by the Chicago Motor Club. This move was made in order to have more time in which to complete the details. The Milwaukee Automobile Club has consented to this change, believing there will be no conflict with the Vanderbilt and Grand Prix.

No attempt will be made to run stock car races as in the past, for it is recognized that it would be almost impossible to get together representative fields. There will be four races as heretofore, but instead of having three races in one day and one the second, there will be two races each day, with the free-for-all the trump card. The complete card is as follows:

FRIDAY, AUGUST 30

AURORA TROPHY RACE.—Open to class C, non-stock, division 3-C, for cars of 231-300 cubic inches piston displacement; distance, 152.5 miles or eighteen laps of the circuit, which is 8 miles 2499 feet in length. Prizes: Aurora trophy and $700 in cash to the winner; $200 to second and $100 to third.

ILLINOIS TROPHY RACE.—Open to class C, non-stock, division 4-C, for cars of 301-450 cubic inches piston displacement; distance, 203 miles 1896 feet or twenty-four laps. Prizes: Illinois trophy and $700 in cash to the winner; $200 to second, and $100 to third.

SATURDAY, AUGUST 31

ELGIN NATIONAL TROPHY RACE.—Open to class E, non-stock, open to class C cars of 600 cubic inches piston displacement and under; made by a factory which has during the 12 months prior to date of the contest produced at least fifty motor cars, not necessarily of the same model; distance, 254 miles, 1050 feet or thirty laps. Prizes: Possession of the Elgin National Trophy for 1 year and $1000 in cash to the winner; $300 for second, and $200 for third.

FREE-FOR-ALL—Open to any car conforming to the definition of a motor car as definited by the American Automobile Association; distance, 306 miles, 920 feet or thirty-six laps. Prizes: $1750 in cash to the winner; $500 to second and $250 to third.

The entry fee in each case will be $100 per car, a reduction from the $300 for first, $200 for second and $100 for the third car charged last year. Also the Elgin association has more than doubled last year's prize fund. Whereas in 1910 and 1911 this amounted to $2,500, this time the association is hanging up $6,000. It is possible for an Elgin National trophy car to run in the free-for-all at the same time, which is likely to augment the field in the big event.

Entries of Big Drivers Expected

No time has been wasted in getting the entries. Fred J. Wagner has been appointed representative of the club in the East, while in the Western territory the work of securing entries will devolve on F. E. Edwards, chairman of the technical committee of the American Automobile Association, who also is a member of the contest committee of the Chicago Automobile Club. Application for a sanction has been made and it is expected that entry blanks will be out early next week. Entries will close August 24.

Tentative nominations already have been made, pending the issuing of the blanks. Ralph Mulford and Erwin Bergdoll both promised to drive at Elgin, and Mulford volunteered to go after the entries of Teddy Tetzlaff, David Bruce-Brown and Ralph de Palma. It also is thought there will be nominations made almost immediately by the Mercer, Cino, Stutz and several others with whose makers members of the club's contest committee have been in touch.

It will not require much work to put the course in shape and Elgin has plenty of time in which to smooth out the wrinkles. Had the deal been closed earlier the backstretch would have been widened, but that will have to wait until another year. The citizens of Elgin are more interested than ever, for when it looked as if the races would be abandoned they began to realize what they were losing.

The deal also marks the return to the promotion field of the Chicago Automobile Club, which has held aloof from the sport since the Crown Point road races in 1909, which were handled by the C. A. C.

Columbus to Have 200-Mile Race

COLUMBUS, O., July 15—At a meeting of the Columbus Automobile Club preliminary plans for a 200-mile race on Sunday, August 25, immediately preceding the opening of the centennial, were made. The race will be held at the Columbus Driving Park.

It is the object of the club to duplicate as nearly as possible the event held last year, and efforts will be made to go even farther. Cash prizes and cups will be awarded the winners.

Though it is probable there will be a number of small events, the 200-mile contest for racing cars will be the chief feature. It is expected that many of the best drivers in the United States will be entered in the program. It will be a free-for-all event. A race for stock cars probably will be included in the program.

The racing course, with the additional work which will be put on it, will be in better condition than last year.

Alco Truck Passes Half-Way Point

OMAHA, NEB., July 11—Acting on the suggestion of the Omaha good roads boosters, the crews of the transcontinental truck decided to go through Nebraska by way of Kearney and Julesburg instead of the original route which included Hastings and McCook.

The road boosters of this city thereupon voted to send out an advance guard which will herald the coming of the Alco along the Platte Valley route.

On account of the interest displayed among business men here and the ovation accorded the truck by the Omaha Commercial Club, the crew remained over a day before putting out "for the farther west."

CENTRAL CITY, NEB., July 12—The climax to many enthusiastic demonstrations along the way was reached today when Mayor Wolz, of Fremont, came East to meet the transcontinental Alco truck. With an escort party he piloted the vehicle for 30 miles and then arranged for pilots and courtesies across the State of Nebraska. The truck today negotiated 133 miles, and it would have covered more but for the delays necessitated by the ovations accorded it. The day's run was made with the temperature at 94 degrees. The half-way point across the continent was passed just west of Kearney; distance, 1,773 miles.

Singer Wins Standard Car Race

LONDON, ENG., July 17 (Special Cable to THE AUTOMOBILE)—The standard car race which was run over 100 laps of the Brooklands course under the auspices of the Royal Automobile Club, of Great Britain, was won by Haywood in a Singer car by a margin of 4-5 of a second. This is a remarkable finish as the length of the course was 277 miles and not more than two lengths separated Haywood from Usmar who was second in a Gladiator. The race was for four-cylinder cars the R. A. C. rating of which could not be more than 20.1. The prizes were £100 for the first car to finish the distance. The second and third prizes were £40 and £10 respectively. Out of fourteen entries there were eight starters, and only three finished. Two Singers, a Vinot, S.C.A.R. and Crespelle retired from the race after starting, while two Stars and a Straker-Squire were disqualified as not being stock cars. Summary:

Car	Driver	Rating	Time h. m. s.	Miles per hour
Singer	Haywood	20.1	4:48:46 4/5	57.49 +
Gladiator	Usmar	15.9	4:48:47 3/5	57.49 —
Turcat-Mery	Engley	20.1	6:18:17	43.88

Vinot ran out its bearings, two Singers broke timing gear chains, while the leading Singer broke an exhaust pipe. Haywood repaired this twice and yet won. Both the winning Singer and the Gladiator went through without tire troubles, although others had numerous punctures and blowouts. The Gladiator made only one stop, that being in the seventy-first lap of the 100-lap race, when the oil supply was replenished.

The specifications required in the race were that the minimum weight of the car should be 2,000 pounds. This was the weight when ready for the race with the driver, mechanic, fuel, oil, water and all tools aboard. The chassis must be of standard touring design all through and must have been shown in the manufacturer's catalogue as such prior to June 25, 1912.

The first stock car race at Brooklands was run last year, the winner being a Star, which averaged 56.24 miles for the 277 miles. That event, however, had a limit of 15.9 on the horsepower and the weight was limited to 1,600 pounds.

Raising Funds for Milwaukee Races

MILWAUKEE, WIS., July 16—The Milwaukee Automobile Dealers' Association, promoter of the Grand Prix, Vanderbilt, Pabst and Wisconsin Challenge road races at Milwaukee on September 17, 20 and 21, is working hard to get together its big fund needed to cover the expense of the reconstruction of Milwaukee county roads, erecting or leasing grand stands and other official stands, and a hundred and one other matters in connection with the running of the big road-racing carnival. While the $50,000 guaranty fund has already been filled by subscription among the big business men, hotelkeepers and individuals, the association is seeking to play safe and sure by adding about $25,000 to the amount.

Dallas Planning Brick Speedway

DALLAS, TEX., July 13—Planning an automobile race track that will rival that in Indianapolis and Atlanta, Secretary Ed. Vaughn of the Dallas Automobile Club has gone to St. Louis and other cities to get capital interested in the movement for this city. A corporation chartered for $200,000 under the laws of Texas is planned to assure the success of the race track. In all probability the course will be built of brick and not asphalt. Already persons in the leading cities of the South have written the Dallas Automobile Club concerning the enterprise and capitalists of Northern cities have evinced a willingness to take part in the enterprise.

Wisconsin Reliability Under Way

BELOIT, WIS., July 15—Fourteen cars entered for the third annual Wisconsin reliability tour for the Sentinel and Emil Schandein cups. Twelve of the entries are trying for the first cup while the other two are in the private owners division and are after the prize donated by Emil Schandein. At the end of the first day's run to Beloit from Milwaukee all had finished with perfect scores. The distance is 112.9 miles.

BARABOO, WIS., July 16—All the cars in the Wisconsin reliability tour finished the second day's run, 134 miles, with perfect scores. About half the distance was over recently-built roads of finest quality. The tourists climbed two of the highest ridges in Wisconsin, crossing the Wisconsin river country to Baraboo. Interest in the tour among the farmers is unabated, and the inhabitants of cities and villages along the route are furnishing elaborate entertainment to the tourists.

Cino Features at Portland

Wins the 5-mile Free-for-All and Breaks Record for 300-Cubic-Inch Cars at Same Distance

Tetzlaff in Big Fiat Only 1 Minute Faster—Christie Car Goes Mile in :53

PORTLAND, ORE., July 10—Portland got a taste of thrills and excitement yesterday during the automobile race meet at the Country Club track. Chris Dundee in "Whistling Billy," the famous White car, went over the bank, while records were smashed and sensations were given the 6,500 persons who packed the grandstand, and occupied hundreds of automobiles.

In the big 300-horsepower Christie, Barney Oldfield made the circuit in 53 seconds flat. The races were featured by the consistent and surprising work of the little 30-horsepower Cino racer driven by Fritsch, who landed victory after victory. Fritsch won the 5-mile free-for-all and was awarded the Budweiser cup. He also won several other races and set a new world's record for cars of the 300 cubic inches piston displacement when he drove 5 miles in the fast time of 4:48. In the big car event Teddy Tetzlaff had to drive his best to go 5 miles in 4:47.

The races started with a 5-mile match between Fritsch, driving his Cino wonder, and Lew Heinemann, piloting the Prince Henry Benz. The timing of the Benz went to the bad and Fritsch came on to win easily in 5:21 1-2, the latter loafing after the foreigner went out. The race was later run over, but Fritsch was put out by an accident. The time was 5:03 2-5.

In the second race Teddy Tetzlaff made a runaway of the event. He was pitted against Verbeck in a 120-horsepower Fiat. Tetzlaff drove rings around his teammates and won as he pleased in the fast time of 4:59.

In the contest for the mile track record, the White driven by Dundee did it in 59 seconds and then went again for a second mile in :54 2-5. Teddy Tetzlaff followed in his Fiat and thundered around the mile track faster than the "Whistling Billy." He turned the mile in 54 seconds flat. Then Oldfield made a new record in the big Christie, turning the course in 53 seconds.

In the last race only Tetzlaff and Fritsch started. Teddy won in the fast time of 4:47, the Cino showing a bad tire.

To Start Metropolitan Speedway

That the period of talk on the proposed speedway on the Jersey meadows is passing and actual work to be commenced seems to be the general opinion of those interested in the proposition. Mr. A. R. Pardington, general manager of the Metropolitan Speedway Association, has made a statement in which he says that "actual work would be started on or before the first of August." It is proposed to have the engineers and workmen who were engaged on the Vanderbilt motor parkway do the work on the new speedway so that the benefit of the 4 years' experience of these operators will be gained.

May Resurrect Fairmount Race

PHILADELPHIA, July 12—In addition to a bill now awaiting action in Councils to the end that the Fairmount Park Commission revoke its action of last spring in abolishing the Fairmount Park road race, a petition addressed to Mayor Blankenburg for renewal of the annual automobile classic is being circulated, largely through the efforts of Harry C. Harbach, former secretary of the Quaker City Motor Club. It is planned to take the responsibility for backing the race out of the hands of the Commissioners and have the municipal authorities stand sponsor, together with local automobile men.

Twenty-four Survive in

Strenuous 8-day Test Over Stiffest Eliminates All but Two Dozen of Most Exhausting on Drivers, Being Punctuated by

VIENNA, AUSTRIA, June 24—What is probably without exception the most arduous and searching test to which the present-day automobile could be subjected ended to-day in Vienna. Eighty-one mud-stained cars, with their occupants weather-beaten and utterly fatigued after their week's toil, rolled up to the club house in the Kamtner Ring during the early evening, and of these no less than twenty-four are shown by the official records to have completed the 1,420 miles without a single stoppage of any kind. This is a wonderful testimony to the endurance and capabilities of the modern automobile, particularly so in view of the fact that when Trieste was reached, 3 days ago, there were only twenty-six cars left in the non-stop list. It was fully expected that half of these would be eliminated by the remainder of the contest, which has embraced some truly awful mountain tracks, and it is a matter of general surprise that only two more cars out of the twenty-six have suffered penalty. With so many victors on hand, the club finds itself in somewhat of a dilemma, for it was always expected that the twelve handsome awards provided by the various Austrian clubs would go round and leave something for the less fortunate competitors. With true eastern feeling the successful drivers have agreed to cast lots for the order of merit, and the difficulty will be solved in this way. As regards the team-prize, the Opel crew takes the first award, for the Minerva-Knight trio, after doing excellently right up to this last day, found their record spoilt through the driver of car 22 missing his gear on the Stubalpe climb.

Of the ninety-five cars entered for the tour (this word is a misnomer, for no rational individual would think of touring over the hilliest part of the Alps at 250 miles per day and without a stop), Austria was represented by forty-one cars; Germany, by thirty-one; Italy presented twelve (all Fiats); France had six; the three Minervas upheld the reputation of Belgium; the Rolls-Royce carried the British flag, while the sole representative of the United States was a standard Ford, which, however, failed to materialize at the starting line along with six others. The Rolls-Royce, too, fell out on the first big climb, for it was geared much too high, and it has therefore fallen to the lot of the Daimler press car, on which THE AUTOMOBILE representative was kindly accorded a seat, to uphold the reputation of both countries. With the Union Jack and the Stars and Stripes (the latter as a tribute to C. Y. Knight) flying from the radiator cap, the Daimler did valiant service, and it should really be added to the list of non-stoppers—though, of course, it could not run in the contest on account of the necessity for photographic stoppages.

Severe Work for All the Drivers

It was the non-stop nature of the work which proved so trying for all the drivers. On these mountain roads—and the committee hunted out all the worst grades they could possibly trace—there is not a 50-yard stretch which does not call for vigilance, and after 250 miles of this game one's brain begins to reel. On three reported instances drivers fell asleep at the wheel—numerous accidents from this cause were only narrowly averted.

The starting hour was 5 each morning; rarely did the bulk of the cars reach the night control till 6 o'clock or later, after a full 12 hours of continuous running. These facts will tend to show how strenuous it has all been and how remarkable it is for the victorious twenty-four to have gone through without a single mark against them.

Many notabilities figured in the contest, and among the eighty-eight starters there were Prince Elias von Parma, the Grand Duke Karl Francis Joseph and the Grand Duke Joseph Ferdinand—the latter a passenger in his own car. The result of this royal patronage—to say nothing of the dozen counts in the running—was that the military element predominated all through.

Austrian Alpine Tour

Grades to Be Found in the Alps Passes the Eighty-one Starters—Contest All the Mountain Highways Many Hairpin Turns

Most of the official observers were army men, and at each village and town on the route soldiers guarded the corners and lined the streets in most solicitous fashion. Another attraction was the one and only lady driver, Miss Helene Morariu, who bravely drove right through with much skill and pluck.

The cars varied in power from the big Mercedes of 70 horsepower to the little Bugatti of but 12 horsepower. On the average about 20 horsepower was most popular. All the cars had to be open four-seaters and all without exception were low-geared on account of the exceptional severity of the mountain tracks—25 per cent. grades being quite common.

But it is very important that the reader should have a clear idea of motoring conditions in Austria, and particularly in the Tyrolese Alps. No one in the world has a better idea of the correct way to make motor roads than the Austrian government engineers, and the chief mountain passes are truly wonderful achievements. When it is said that our Daimler-Knight on two occasions—the Broccone and the Monte Mauria Passes—climbed up above the 5,000 foot level without dropping below third gear it will be appreciated that much skill has been expended in winding the road along the mountain side, with plentiful use of hairpin corners to ease the grade. Regarding these hairpins, there are no less than twenty-eight on the ascent of the Pordoi Pass, while the classical example of the Stelvio, where the road rises to a height of over 9,000 feet, has forty-six hairpin corners on the Austrian side and nearly as many on the descent into Italy.

Picturesque Features of Tour

The roads in the Tyrol are magnificent—their surface is, in general, quite up to the level of their easiness of grade. As a touring district the country is in every way to be preferred to Switzerland, which should be boycotted by every motorist on account of the existence of the interminable anti-automobile laws and regulations. In regard to scenery, too, the Tyrolese Alps are second to none; the beautiful white Dolomites create a lasting impression on the mind, and the view of these high and rugged peaks from the Broccone Pass is one never to be forgotten. Let the reader of these lines who purposes running his car in Europe start off from Trieste (whither his car can conveniently be shipped) and follow the itinerary of this Austrian Alpine tour. The results will without doubt provide a most enjoyable remembrance of a delightful tour.

To deal in brief with the details of the contest, it was on Sunday, June 16, that the cars were despatched from Vienna at 5 a. m. on their 250-mile run to Spittal. German drivers are proverbial speed-merchants, and till the mountain country was reached, some 50 miles south, the pace was up to the limit of each car's capabilities. But let it be said that there is a great deal more bark than bite about these pointed-nose, wind-cutting touring cars; they race past you at 50 miles an hour, with deafening exhaust, scattering the stones and raising the dust in high clouds. As soon as a hill is reached, however, back they come, and at the summit one has the pleasant satisfaction of knowing that they are toiling slowly up, some miles in the rear.

The Semmering, once the scene of historic climbing events, was the first of the passes, but the modern car has advanced to such levels that this 4,000-foot ascent was hardly enough to slacken progress. On this first day's run the severe climbing was not encountered till 200 miles had been traversed; then, however, there was enough to satisfy the most ambitious. An old Roman road had been unearthed at Tauem, and so steep was it that six cars failed utterly, including the big Rolls-Royce, while seven or eight more suffered delays and had to pay penalty marks. Ten miles farther on came the Katschberg—a grade of something worse than 25 per cent. and with a fearful surface. All the cars which had toiled up the Tauern managed to crawl up this climb, but the boiling radiators told their own tale of

The Grif & Stift car spinning around the curves of the road through the Monte Maggiore Pass

laboring engines. Thus was Spittal reached with over twenty cars out of the non-stop running.

On Monday the objective was Trento—in an Austrian district where Italian speech and customs still survive. On this run came the Bruneck (4,200 feet), Jauffen (5,500 feet) and Mendel Passes (the latter rising to 4,500 feet), and the competitors had enough and to spare of hairpin bends and hill-climbing work before the day was over. Fortunately, the roads are wonderfully good as regards surface and little or no tire trouble was experienced—in pleasant contrast to the opening day's journey, on which the rough going played havoc with the casings.

Then followed the wonderful Dolomiteristrasse—a magnificent highway constructed by the Austrian Government after 16 years of work, at a cost of over 4,000,000 kronen ($800,000). No less than five times does the road rise to a height of above 5,000 feet; on the Pordoi the 7,000 feet level is passed, and on the Falzareggo this is only missed by some 30 feet. All along the road magnificent panoramas of mountain peaks and valleys open themselves out, and it may be said, without fear of contradiction, that this run across the Dolomites is the finest day's journey available in the whole of Europe. For the average driver of the average car there is not a single danger point on the run; care has, of course, to be exercised when descending these mountains by reason of the hairpin bends, which can only be rounded at a slow pace. Otherwise, the car can be allowed to coast down at a good speed, with the comforting knowledge that nowhere on the descent will the grade become steeper than 8 per cent.

Three Fatalities During Tour

After the fourth day's run to Trieste, on the Adriatic, the route ran to the borders of Bosnia, and it was here, on the Monte Maggiore Pass, that the only fatal accident took place. It was the old story of taking risks; a front spring was cracked through, but the driver refused to stop and be penalized. At the first bend of the descent the driver lost control of the car, the result being that three of its passengers were killed. This car was No. 5, driven by Fischer, and an extraordinary coincidence has to be related in that another driver named Fischer passing this place soon afterwards fell asleep at the wheel and ran his car into the side of the road. Fortunately no serious damage was done.

No other accidents occurred to mar the event, and, as was stated before, despite the exceptional severity of the side roads traversed on the last 2 day's route, no cars fell out of the running and the twenty-four drivers who arrived at Vienna this evening can congratulate themselves on having emerged triumphantly from the most strenuous trial in automobile history.

Canada Holding Up Tourists

MONTREAL, CAN., July 13—The following notice as to customs regulations is being sent to members of the Automobile Club of Canada by the secretary and is of prime importance in view of the recent holding up of the cars of two Montreal motorists at the border:

"We beg to draw your attention to the importance of strictly observing the customs regulations when crossing the international boundary between Canada and the United States. Motorists are required to stop and report at the frontier port in all cases and not at some interior port. The American customs department is now rigidly enforcing this regulation, and the Canadian customs likewise. It is necessary for motorists to report at the Canadian frontier port when leaving Canada, and at the first frontier port when entering the States; on the return journey the same formalities must be carried out.

"In cases where the tourist intends stopping from 1 to 3 days only in the States, the officer may use his discretion and waive the requirement of a bond, but for a longer period, not exceeding 6 months, a bond is required, and may be secured at most of the frontier offices, while you wait, at a reasonable fee. For your information we give hereunder the frontier ports of the principal routes in this section of the province, where motorists are required to stop:

Canada.	United States.
Lacolle Junction.	Rouses Point, N. Y.
Noyan Junction.	Alburgh, Vt.
Abercorn.	Richford, Vt.
Mansonville.	North Tray, Vt.

Hemmingford.	Ft. Covington, N. Y.
St. Armand.	Mooer's Junction, N. Y.
Rock Island.	St. Alban's, Vt.
Coaticook.	Derby Line, Vt.
Comin's Mills (to July 1st).	Island Pond, Vt.
Hall's Stream (after July 1st).	Beechers Falls, Vt.

Elements That Affect Truck Tire Guarantees

Too Much Speed and Overloading Must Be Considered, as Well as Proper Distribution of Load

Local Conditions, Such as Hilly Streets and Poor Paving Should Also Be Taken Into Account

WHY is it when solid-tire makers guarantee mileage delivered by their product from 8,000 to 10,000, and where certain large users can get an average of 1,000 miles more than the extreme guaranteed figure, that one of the chief complaints heard about truck operation is that some of the users of that form of transportation fail to get the guaranteed figures from their tires?

Why is it that in regular service one company can get over 30,000 miles from an exceptional tire and as low as 2,500 miles from another?

The answer lies in the difference in service conditions.

Standard brands are not very unlike, one from the other, differing only in some of the structural details. The fact that the guarantees under which they are sold are similar, speaks clearly on that point.

The exact fact is that the standard tires must be good for the guaranteed mileage or the guarantees would bankrupt the makers. Guarantees are not made on wild claims, but are based upon long experience and careful compilation of data covering years of service.

As to Maker's Tire Guarantees

The truck-using public is still uncertain as to the significance of tire guarantees. As a matter of common practice, the user is told that the tires he purchases are guaranteed by their makers for 8,000 or 10,000 miles under certain conditions. If he can get more than the guaranteed mileage, he is that much winner; if he falls below, he can obtain an adjustment from the tire company that made the goods.

On the face of it, it would seem that tire costs ought to be one of the least troublesome items in truck operation, but the contrary is the truth.

The difficulty lies in the fact that there are numerous obstacles in operating trucks that make for short life of tires. These may be grouped in a general way as follows:

Character of road surface.
Excessive grades.
Overloading.
Overspeeding.
Bad distribution of loads.

The first four elements may be passed over briefly, as they are generally recognized by truck users and will only be considered with relation to their bearing upon the last factor in tire abuse.

It is quite apparent that if a road surface is sufficiently rough that tires will suffer no matter how moderate the loading or speeding may be. An excessive grade will impose an unwarranted strain upon tire equipment without reference to any other factor.

Overloading the tires will break them down and cause short mileage, and overspeeding will result in burnt-out tires under the inexorable rule of V^2.

The two latter subjects are taken into consideration by the tire makers in framing their tabular guarantees, and the first two are so thoroughly recognized that there is no further need of discussing them.

But with regard to poor distribution of the load, the users of automobile trucks are just beginning to recognize its importance as a factor in reduced tire mileages. Some of the makers and sellers are not quite clear on the point, although numerous claims for adjustments for as much as 3,000 miles per tire have been presented to several of them.

A recent case presented to the B. F. Goodrich Company for adjustment gives an excellent idea of the principle involved. In the case in point, a Pierce-Arrow 5-ton truck used for hauling metal and equipped with adequate tires and run within the speed and load limits of the guarantee, failed to deliver the mileage. The dual rear tires wore out about 2,500 miles short of the guaranteed figure and an adjustment was demanded by the user. It was shown that while in this particular model of car and the special body used, 90 per cent. of the load should have been carried by the rear wheels, that in practice, the owner of the truck placed 98 per cent. of the load over the rear axle and upon the extension back of the axle. The road surfaces were poor and some heavy grades had to be surmounted and the tires gave way.

Excessive Weight on Tires

The speed rate was well within the limit, and as the actual maximum load carried was just the rated amount for the tire equipment, the user could not understand why the tires failed to stand up until it was explained to him that the continuous use of the truck with 8 per cent. excessive weight on the rear tires was sufficient to account for their failure.

In this case the rated load was 10,000 pounds, of which 9,000 pounds should have been carried on the rear axle. But the convenience of loading and unloading caused the user to place the whole load upon or so near to the bearing point upon the rear axle that tests showed it carried 9,800 pounds, exclusive of the empty weight, and the extra 800 pounds did the business for the tires in steady service.

Another case, illustrative of a different phase of bad loading, was that of a Peerless 3-ton truck equipped with sufficient tires for its rated load. The car was designed to carry 77.5 per cent. of its total loaded weight on the rear axle and in practice the user

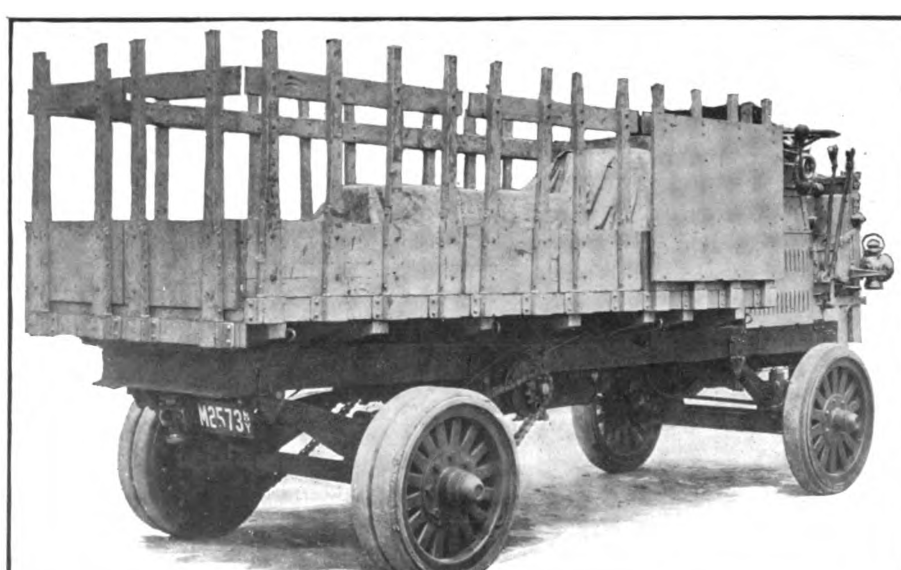

Fig. 1—In cars of the motor-under-the-seat type, such as this 5-ton General Motors Company truck, the life of tires depends in a measure upon an even distribution of the load. The heavy front tires are designed to carry 40 per cent, and in this illustration a 4-ton casting and a barrel of white lead are correctly placed

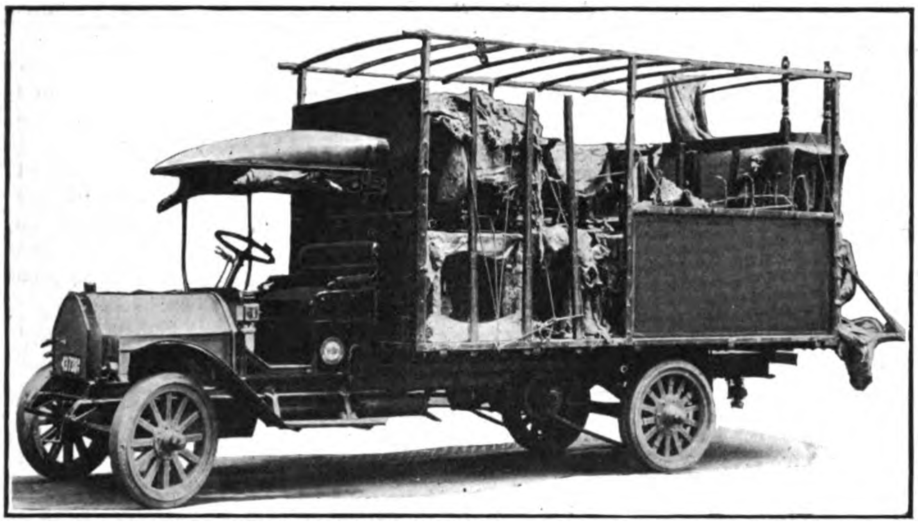

Fig. 2—Velie 2-ton truck, a type of the motor-in-front style of construction which allows 3-4 of the total weight to be carried on the rear axle. With such light bulky freight as furniture the best practice is to put the heavier articles to the front of the center of gravity

kept well within the limit of load and speed except for 1 day's service, when it was necessary to move a load of steel castings in addition to its ordinary and usual load of light, bulky merchandise. The total load carried that day on a run of 22 miles was exactly the rated load of the truck, but the castings were placed amidships with the result that the front tires carried 48 per cent. of the load of freight. Two weeks later in ordinary service, both front tires pegged out.

The tires had been in service for 7,000 miles and up to the time of the single instance of misuse, appeared to be good for at least 5,000 miles more. A careful inspection of the ruined tires showed that the structure of the rubber had been changed and that it had lost a large measure of its original resiliency where it had not been disintegrated.

The two cases cited show the effect of constant overloading of one set of wheels and of a single case of overloading. In both cases the results attained are similar—the destruction of the tires.

Various Forms of Guarantee

The manufacturers of truck tires, such as the Goodyear and United States Tire Company, guarantee 10,000 miles conditioned upon moderate speed and rated load. Other companies place their guaranteed figures at 8,000 miles. Among these concerns are Goodrich, Diamond, Swinehart and various others. The Firestone company's guarantee is framed on slightly different lines, but long experience has shown that it is equal to about 8,000 miles.

The Firestone guarantee is as follows:

"When subjected to no greater loads, and run at no greater speeds than specified in our schedule, we guarantee Firestone Motor Truck Tires as follows:

"12 months on cars not exceeding 25 miles daily service.

"10 months on cars not exceeding 25 to 35 miles daily service.

"7 months on cars not exceeding 35 to 50 miles daily service.

"4 months on cars not exceeding 50 to 75 miles daily service.

"3 months on cars not exceeding 75 to 100 miles daily service."

The load limit per wheel upon which the B. F. Goodrich Company bases its guarantees is set forth in the tabulations below covering both the single and dual types of tires.

Practically all solid tires are now made in conformance with the specifications of wheel sizes and dimensions laid down by the S. A. E., thus simplifying the problem of the manufacturer as to

MAXIMUM LOAD TO BE CARRIED BY FIRESTONE SOLID MOTOR TRUCK TIRES PER WHEEL

odd-sizes and allowing him to center attention on the standard sizes.

Analyzing the guarantee of any of the standard companies shows that the wheel-load is taken as the unit. Time was when the guarantee covered a certain minimum number of miles at a certain maximum carried load, but the modern practice is to regard each wheel as a separate problem. So far, the shifting of the load from one side to the other so that extra stress has to be borne by one wheel, either front or rear, has not been considered in a definite way, but emphasis is laid in 1912 on the fact that each set of wheels must be adequately tired in order to enjoy the guarantee of the manufacturers.

An excellent way to determine what tire equipment to use on a certain track is to load it as heavily as it is ever likely to be loaded in service and then weigh the front end and the rear end of the loaded car. Suppose that the truck in question is rated at 3 tons carrying capacity, entirely disregarding the factor of overload allowed under the guarantee furnished by its manufacturer.

Fig. 3—Packard 3-ton truck with full load of pianos. Note that the middle pair stand only a trifle in front of the rear axle and that the end pair and forward pair balance each other in such a way as to throw almost 90 per cent. of the load weight on the rear wheels

GENERAL DIMENSIONS—DUAL TYPE

Suppose that the load placed upon the truck weighs 6,000 pounds and the car with its body, driver and supplies weighs, say, 7,200 pounds, or a total of 13,200 pounds.

The car will probably fall within one of three classes of design. It may be propelled by a gasoline motor located in front under the hood, the driver sitting behind the motor; or it may be driven by a motor placed back under the driver's seat; or, again, it may be an electric with the batteries swung under the platform and bearing about equally upon all four wheels. If in the first general class the percentage of load to be carried on the rear wheels, including chassis and body weight, runs as high as 92 per cent. In such well-known makes in the 3-ton size as Grabowsky, the percentage of weight carried by the rear wheels is 60; Packard, 72; Peerless, 77.5; Velie, 75.

In the second class cited, the following examples show the general idea: Sampson, 66; Garford, 60; Hewitt, 60; Mack, 62.

Load Divided Between Axles

In the electrics of the 3-ton size the load is well divided between the axles, the proportion being about 45 to 55. Of course, in all the cases used for illustration the type of body makes all the difference in the world about the ratio of load to be carried by each set of wheels. If a short body is used the tendency would be to lessen the percentage of weight carried by the rear wheels. If a long overhang is the type selected, the rear wheels must carry a higher percentage of the load than is indicated by the figures.

Suppose that the car in question is a Velie, which in the regular type is supposed to carry 75 per cent. of its total load on the rear axle. If the figures of the weighmaster show that the front end of the loaded car weighs 3,300 and the rear end 9,900 the user should divide each number by 2 to give the weight-rate for each wheel. Then by turning to the tabulation of tire sizes in relation to loads it is a simple matter to pick out the size recommended to carry a shade more weight than is shown by the division.

In this case the rated weight for the front wheels would be 1,650 pounds, which calls for a single type of front tire not less than 4 inches wide. This model is equipped with dual rear wheels and the weight to be carried will be found to be 4,950 pounds per wheel. Dual rear tires at least 4 inches wide are recommended by the manufacturer; in fact, 5-inch tires are supplied as stock equipment.

If a Packard, equipped with a long overhang and designed to carry more of the freight on the rear axle than the foregoing example, should be used, and the weight on the rear wheels should reach 6,000 pounds per wheel, dual tires of at least 5 inches in width would be indicated.

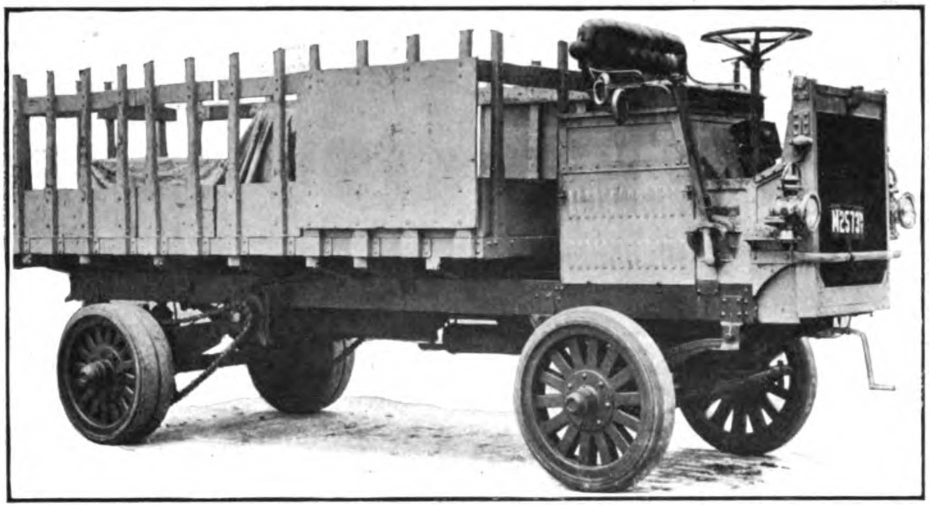

Fig. 4—In this picture of the General Motors Company 5-ton truck the casting, weighing 4 tons, and the barrel of white lead are placed too far aft, and if carried in those positions would make short work of the best tires. Loading, in the final analysis, must depend largely on the intelligence of the driver, because each trip presents its own problem

The tire makers say that the solution of the problem requires individual treatment. They say that no matter what type of car, body and capacity is considered, the simple expedient of weighing both ends of it loaded and then providing the size of tires indicated for service will insure maximum mileage, always providing that the loads are so distributed as to equalize the tire burdens in conformance with their size and ability to bear them.

In every truck on the market, irrespective of whether or not a special point is made of the fact, there is a margin of safety in the construction. In some cases a limit to overload is specified that is far below what the truck is able to carry. The manufacturers insist that they shall not be held liable for mishaps in case the load-tolerance is exceeded by the user. Nevertheless, many truck operators habitually press the limit of overload. So far as the truck itself is concerned the user may be able to overload to the limit of the rated tolerance without doing appreciable damage to the mechanism. But when it comes to the tires, why that is a different story again, as Mr. Glass says. There is no margin of safety in the tires. They have no overload capacity.

They are built to carry a certain maximum load at a certain maximum speed and until it is possible to give rubber composition an overload capacity the result of overloading will always be less mileage and tire life.

Of course, there is one way to accomplish such a result. If the user finds that the maximum load to be carried by the tires calls for 4-inch singles in front and 5-inch duals behind, he may put on 5-inch singles in front and 7-inch duals behind and go clear to the limit of load-tolerance allowed by the manufacturer without losing the benefits of his guarantee on car or tires.

This plan is not economic in its principles and does not work out satisfactorily as a theory, but it surely works splendidly in actual practice. Take one of the largest express companies in the country, for example. The engineers of this company soon after the introduction of the automobile learned that under-tiring was an expensive proposition. Many trucks were operated early in the history of the industry and the battery has been tremendously increased with each step toward improvement in construction. Nearly 7 years ago the conclusion was reached that larger tires would add to tire mileages and the result is to be seen in the average of 11,182 miles per tire, which is the amount delivered by those in service of this company.

The United States Tire Company bases its guarantees and recommendations as to loading on the following tabulation:

GENERAL DIMENSIONS OF UNITED STATES STANDARD SOLID MOTOR TIRES (DEMOUNTABLE)

Single Tires										Dual Tires	
Width of Tire	Height of Tire	Overall Width	Flange Wedge	Carrying Capacity	Nominal Tire Size	Width of Tire	Height of Tire	Overall Width	Flange Wedge	Center Wedge	Carrying Capacity

Express Work a Severe Test

Express service is a severe test of truck efficiency and the equalization of loads to tire equipment is a difficult problem for such companies. This is due to the character of much of the service required where deliveries are made at short intervals, or where loads are picked up along regular routes. In the freight service between depots and warehouses or distributing stations the matter can be given more care. Part of the satisfactory showing made by the tires of this company's automobile service is undoubtedly due to the careful adjustment of the loads to the tire equipment per wheel.

For the purpose of illustrating another factor in the problem of tire life in connection with proper loading, the street conditions in various American cities are interesting, particularly with reference to the mileages delivered. New York has a total of 2,707 miles of paved streets involving every grade and type of pavement known to mankind and averaging from poor to fair. The cobble pavements and sharp-edged stone blocks are destructive to truck tires in New York as may be seen from the fact that fragmentary data indicate an average of only 6,161 miles per tire used on all classes of commercial vehicles excepting omnibuses in the metropolis.

THE SOCIETY OF AUTOMOBILE ENGINEERS IN AIDING THE STANDARDIZATION OF PRACTICE WITH REGARD TO WHEEL DIMENSIONS HAS ADOPTED THE FOLLOWING STANDARDS:

S. A. E. WHEEL DIMENSIONS FOR SOLID TIRES
NON-DEMOUNTABLE AND DEMOUNTABLE EQUIPMENT

All Dimensions in Inches
Single Tires

Sectional size of tire	2	2½	3	3½	4	4½	5	5½	6	6½	7	7½	8
Width of felloe and band	1[illegible]	1[illegible]	2[illegible]	2[illegible]	3[illegible]	3[illegible]	4[illegible]	4[illegible]	5[illegible]	5[illegible]	6[illegible]	6[illegible]	7[illegible]
Thickness of steel band	[illegible]	[illegible]	[illegible]	[illegible]	[illegible]	[illegible]	[illegible]	[illegible]	[illegible]	[illegible]	[illegible]	[illegible]	[illegible]

Dual Tires

Sectional size of tire	2	2½	3	3½	4	4½	5	5½	6	6½	7	7½	8
Width of felloe and band	4	5	6	7	8	9	10	11	12	13	14	15	16
Thickness of steel band	[illegible]	[illegible]	[illegible]	[illegible]	[illegible]	[illegible]	[illegible]	[illegible]	[illegible]	[illegible]	[illegible]	[illegible]	[illegible]
Minimum thickness of felloe	1[illegible]	1[illegible]	1[illegible]	1½	1[illegible]	1[illegible]	2	2	2	2[illegible]	2[illegible]	2[illegible]	2[illegible]

Wheel Diameter Over Steel Band
Single and Dual Tires

Nominal outside diameter of tire	30	32	34	36	38	40	42
Wheel diameter over steel band	24	26	28	30	32	34	36
Exact wheel circumference over steel band. No shrinkage allowed	75 [illegible]	81 [illegible]	87[illegible]	94¼	100[illegible]	106 [illegible]	113[illegible]
Tolerance over exact circumference of bands before application to wheel	75 [illegible]	81[illegible]	88[illegible]	94[illegible]	100[illegible]	106[illegible]	113[illegible]
Tolerance over exact circumference of bands after application to wheel	75 [illegible]	81 [illegible]	88[illegible]	94[illegible]	100[illegible]	106 [illegible]	113[illegible]

Bolt Equipment for Side Flanges
Bolt Hole Circle
All Bolts to be ½" Diameter

Outside diameter of tire	26	28	30	32	34	36	38	40	42	44	46	48	50	52	54
Diameter bolt hole circle	18½	20½	22½	24½	26½	28½	30½	32½	34½	36½	38½	40½	42½	44½	46½
Number of bolts	6 or	9 or	18	8 or	12 or	24	10 or	15 or	30	12 or	18 or	36	14 or	21 or	42

A very large percentage of this astonishing showing is undoubtedly due to habitual overloading and overspeeding, but the lack of intelligent loading so that the weight carried on each wheel corresponds with the capacity of the tire unquestionably has some effect.

Baltimore Is Hardest on Tires

The extraordinary mileage achieved with tires used on bus lines raises the average to 8,274. These figures appear to be out of proportion, but it should be taken into consideration that all of the 8,000 commercial cars owned in New York were not reported and that all the buses were reported. Another angle may be viewed when it is understood that the buses travel only the best streets.

Baltimore, with its vicious pavements and lack of them, has the worst record in the United States, although Pittsburgh with its hills, Seattle located on the slope of the Cascade Mountains and San Francisco with its fierce grades, are not far behind. In Kansas City, where the hills are insurmountable for the average truck, the record is better, reaching 8,000 miles per tire, or approximately the guaranteed figures. In Baltimore the mileage average is 4,024. The difference is due solely to the variation in street conditions, as Baltimore grades are as flat as a spirit level compared with those of Kansas City.

In Chicago, which is as flat as a board, but where paving conditions are not quite perfect, the average mileage delivered per tire is 8,115. In St. Louis, which has more hills but better surfaces, the mileage is 9,793. Washington, with its fine streets and level general surface, is reported as giving 15,000 miles per tire, but the figures are based upon insufficient data as compared with the large use of the truck in the capital. Another factor in the Washington situation is that electrics of 1 and 2-ton capacity are largely used with oversize tires. Still another is the sharp application of the speed laws.

The highest percentage of asphalt streets, or equivalent pavement, is found in Kansas City, where the proportion is 64 per cent. Washington has less than 50 per cent., Baltimore only 9.28 per cent. and Boston 4.3 per cent. The deduction to be drawn from the figures is that where there is a good road surface the tires last disproportionately longer than that factor would seem to justify, despite heavy grades and fast service. Where there are good roads and streets and few grades the increase in mileage is astonishing. The ideal condition will be found where smooth, traction-giving roads, level grades and

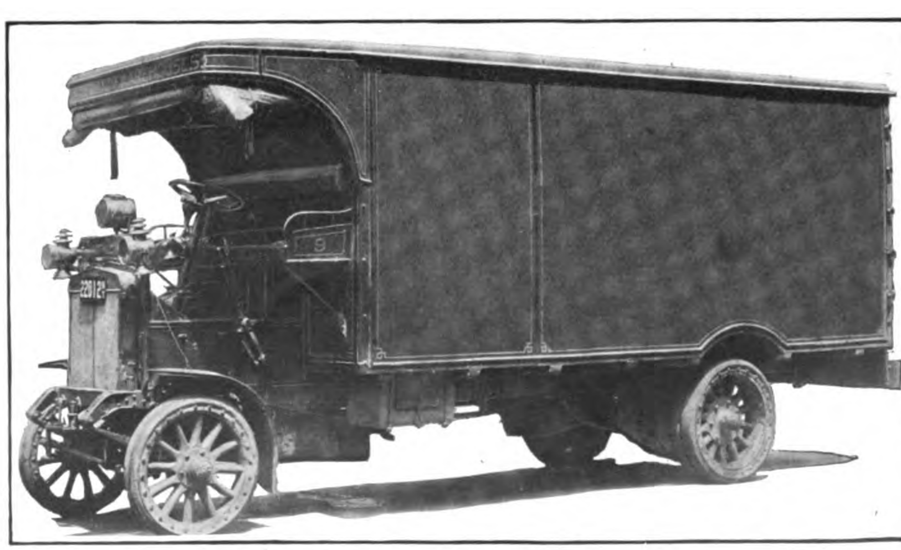

Fig. 5—Sampson 3-ton truck equipped with a very heavy van body. The chassis structure of the Sampson lends itself to this type of service, and in this particular wagon the weight is so evenly distributed that loading of furniture makes little difference in tire wear

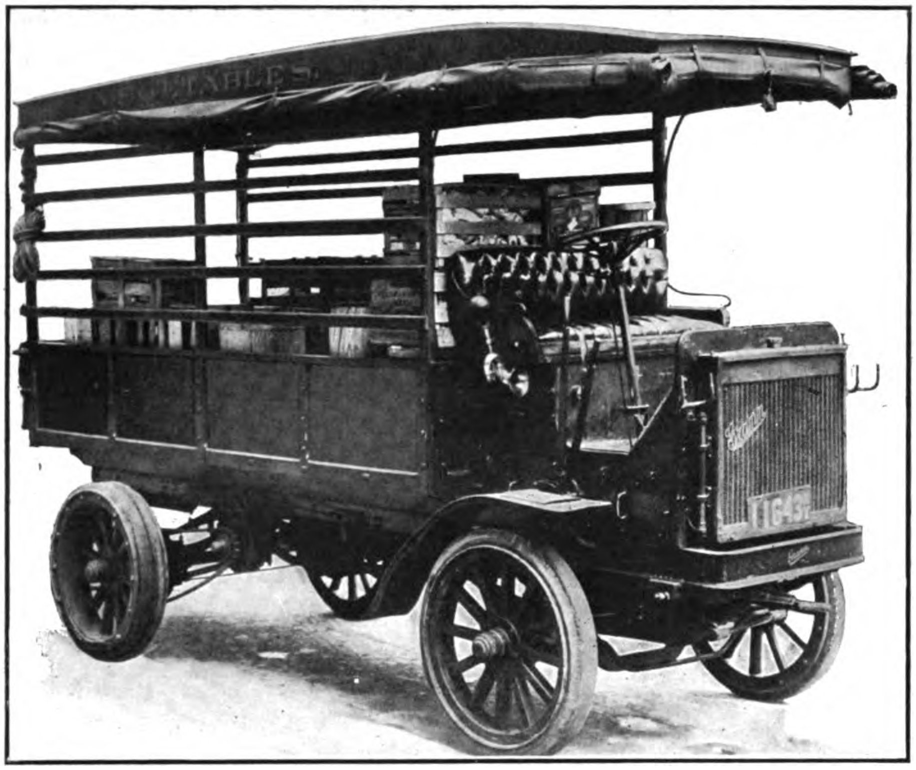

Fig. 6—Gramm truck which ordinarily carries too much of its heavy freight on the rear axle, as indicated by the frayed condition of the inner dual tires. In this picture the heavy packages have been unloaded, and the light stuff forward is shown as an ideal distribution of weight

moderate speed and load are combined, together with a nice discrimination as to distributing the load.

At this date the best place in the United States for tire mileages is Washington and three of the factors mentioned above are present, while the other two have considerable weight in making up the sum.

Tire Expert on Overloading

An expert in solid tires explained the precise effect of overloading, which includes unequal distribution of weight as treated in this article, as follows:

"In the process of manufacture, crude gum is mixed with pigments and the whole mass is kneaded together until the compound becomes homogeneous. After various intermediate steps, the rubber is placed in a mold and vulcanized. During vulcanization the tire assumes a more or less permanent form to which it will normally return if it is not stretched or compressed beyond certain definite limits. If the stretching or compression exceeds these limits, however, the strain will invariably cause a rupture or disintegration of the rubber.

"To illustrate: Take a strong, properly vulcanized rubber band. Stretch it moderately, release it, and it will return to its normal shape. The process may be repeated indefinitely, depending upon the quality of the rubber, and the band will resume its shape. Stretch it beyond its limit of elongation, however, and what happens? The rubber breaks and all the king's horses and all the king's men can't restore it to its previous condition.

"The damage has been done and the rupture is permanent. Similarly, a piece of rubber properly vulcanized may be compressed within certain limits, released, and it will resume its normal shape. The compression may be repeated an indefinite number of times, depending on the quality of the compound. So long as its limit of compression has not been reached, the rubber will continue to spring back into shape and nothing but abrasion or other physical or chemical action will destroy its elasticity.

"Compress it beyond its limit of cohesion, however, or, in other words, beyond its power of resistance, and the rubber breaks down or ruptures just as inevitably as in the case of stretching beyond its limit of elongation. No method yet devised will restore to the unit its former elastic qualities. The difference between a rupture resulting from compression and one brought about by stretching is that in the latter the tear usually results in a clean separation, while in the former the rupture may not be noticeable because the broken parts are held in place by others not yet noticeably affected.

"Nevertheless the damage is done, and disintegration has commenced, not because the average load exceeded the limit of resistance, but because some one load exceeded it, and started the rupture."

The owner should always bear in mind that poor results with any make of truck tire are comparatively seldom due to defects in the materials or in the manufacture of the tires themselves, but may be reasonably expected should he shift to some other make of tires in the hope of obtaining better service. He must always figure on a considerable deterioration in the tires caused by wear and tear of everyday, knockabout, rough use over all sorts of pavements and roads and under all sorts of weather conditions, from the torrid days of July and August, when the superheated asphalt and dirt of the highways over which the truck is obliged to travel well-nigh blister the tortured rubber as it toils on its rotary path, to the frigid days of December and January when the cold contracts the rubber and the ice and snow insidiously permeate the pores of the tread as it bumps over the frozen ruts in the roadway, receiving severe blows and sometimes cuts from stones and sharp pieces of ice.

Then, too, he must consider the character of the load to be carried by the machine, whether it is light or heavy, etc., for this has a great deal to do with the life of the tires, especially as regards the problem of scientific loading.

Driver Most Important Factor

But the factor which is most important in determining the length of life of the tires is the factor which it is most difficult to regulate—the personal equation. Some truck owners have the idea that, after they have bought their truck, or trucks, as the case may be, they have only to get a man who is capable of starting and steering the machine about the streets without running into things too often, and of changing gear or even making minor repairs when necessary. This is far from the true state of affairs at this juncture. The owner should remember that his own interests are at stake, that the sort of a driver he employs means dollars and cents to him, not only in the service he gets out of the truck, but also in the size and frequency of repair bills and, last but not least, in the amount of money he will be obliged to pay out for new tires.

Too much emphasis cannot be laid upon the importance to the truck owner of this question of selecting a driver who knows his business, who knows his automobile mechanics, and, above all, who appreciates the points of good truck driving and is proud of his knowledge in this respect and of his application of this knowledge. For there is more science to be found in truck driving than in a great many other pursuits which claim higher places in the sphere of business. It presents a practically limitless field for the application of mathematical principles and unbounded opportunity for the acquirement of manual dexterity and of mechanical skill.

Best Varnish Is Essential

Good Service Cannot Be Expected of This Beautifier and Protector if Made of Poor Materials

Varnish Must Be Allowed to Ripen Properly Before Using —Storage Place Should Be Uniformly Warm

VARNISH, of all the materials which are applied to the car to make it beautiful and give pleasure to the user, is at once the most sensitive and the most durable. Once assembled on the surface of the car in splendid unity it immediately becomes all things to practically all men.

The service it yields is manifold. Chiefly it is a protector and a beautifier. The varnish user demands that it should work precisely right under all circumstances. It must dry free from dust in the nick of time. It must have an undiminished luster. It must neither sweat, nor pit, nor enamel, nor do other hot-weather tricks. In a word, it must be a garment suited to all kinds of weather.

Varnish making is one of the most highly skilled industries. It is an achievement of science and chemistry. Every varnish maker has special formulæ and methods of manufacture, and mechanical equipment of the finest sort, and to-day varnish, prepared and ready for use, represents the finished product of highly specialized mechanical, scientific and chemical skill.

The laymen with his crude little outfit and his ancient formula cautiously extracted from age-worn tomes should be labeled "handle with care" when he sets forth to school the unsophisticated public in the mystery of making varnish. The automobile painter and the automobile owner should deal directly with the reliable maker of varnish who, with the experience and prestige of years of business, is able and glad to stand back of his products. In this way mutual interests may be safeguarded and the finish applied to the car given a prolonged lease of life.

Automobile varnish of the best quality is made of a combination of copal gum, a product of Africa, and turpentine and linseed oil. Zanzibar copal is said to yield a varnish of the very highest quality.

Many inferior gums or resins, turpentine substitutes, and adulterated linseed oil are consumed in making varnishes for automobile work, but all such varnishes are cheap only in the matter of price. In the end they are the most expensive materials purchasable.

Avoid the Use of Cheap Varnish

All cheap varnishes live on the surface of the car for a comparatively short period only. They lack the vital bone and sinew, and from the very first they are stricken with the "shadow of things to come." Such varnishes, of course, dry hard and fast in short order, but once dry and the story of their decline begins. They are devoid of the elastic properties and of the strength which comes alone from the rich and robust African gum.

It is therefore in order, first of all, for the car owner doing business with the painter to have it stipulated in the contract that a high-class varnish be used on the car.

Varnish should never be used until it is well aged and ripened. The leading varnish makers have thousands of gallons of varnish of the various grades tanked, and held for mellowing out, and taking on a condition, and an appearance, and an age that will make it rare and good, and distinguished in its class.

The untrained counselor in the ways of making varnish who would for some money consideration put the painter in the way of being his own varnish maker knows little, and apparently cares less, concerning this practice of giving age and a ripe condition to varnish before using it. Nothing, however, is more essential; nothing has more to do with its excellence and nothing has more to do with the results obtained.

Even the working of varnish, its brilliancy, and its other characteristics cropping out in a hundred ways on the surface of the car, are in no small measure influenced and controlled by the manner of keeping the varnish preparatory for use. It should be kept in a warm room, preferably upon a shelf located at a point 5 or 6 feet above the floor.

This situation should be dry, and the warmth should be uniform. Varying temperatures keep a varnish in a state of unrest, whereas fine varnish should be disturbed as little as possible.

In not a few publications devoted to things pertaining to the automobile instructions have lately been handed out describing how to use varnish, and quite often these ways are more amusing than instructive. For example, we note that painters are gravely told to apply varnish thin and wipe it out over the surface thoroughly. Such information should under no circumstances be put into practice.

How Varnish Should Be Applied

Varnish should be applied to the surface in a rich, full volume, making the surface carry all it can assimilate and take care of. In this way, and only in this way, is the deep, lustrous, mirror-like surface so greatly to be desired on the automobile developed and rounded out.

Thin, skimpy, laboriously brushed-on coats of varnish are the natural forerunners of seedy, specky, dull, unsatisfying finished surfaces.

Any car owner who doesn't feel qualified to put on and handle such coats of varnish had better turn the work over to the professional painter, who by occupation is an adept in such things.

Rubbing varnish which precedes the finishing varnish on the surface—in fact, going directly over the color—is used for the purpose of building up a surface level and smooth and strong to support the finishing varnish coat.

Rubbing varnish is made up in a different manner from finishing varnish in that it carries harder gums, less oil, and has generally a different composition of ingredients. It is chiefly a bodying up medium, but like the finishing varnish it should be a first-class article. Great things are expected of it.

The fine, clean, smooth, and level surface which the automobile must have to please its owner is worked out in this way: As soon as the color or combination of colors are placed in position upon the surface the entry of rubbing varnish is made. It must, to meet requirements, go to the surface as free from brush marks and roughness as possible. Lacking the flowing properties of finishing varnish, it seldom works out to the same degree of fineness. But if kept clean and worked quickly and skilfully all the natural roughness of the coats will be held down to the minimum. Then in the rubbing use perforated rubbing pads of heavy felt, wet, and dipped in No. 00 pulverized pumice stone. Use plenty of the pumice stone until the desired surface is practically reached, whereupon finish off with a clean piece of felt dipped freely in water; giving the surface, in fact, a water rub. Then wash up carefully and follow with the finishing coat of varnish.

GERMANY, during this year's military manœuvres, is demonstrating the constantly increasing commercial importance—some say indispensability—of the motor car. The reading public know well the use that Germany is making of the automobile for army purposes. It is true that, owing to the expense of maintaining a motor car park, the automobile army corps has never been completely mobilized in the German army. Therefore an authentic test of the total complicated apparatus, including portable workshops, gasoline and tire stations, has never been entirely demonstrated. This leaves Germany behind France in respect of statistical details.

Nougier Discovers that Formulas for Adiabatic Compression Point Way to Recovery of Thermic Waste in Combustion Engines and Many Other Gains Besides—New Porous Metal Multiplies Battery Capacity—Diesel Locomotives

DIESEL System for Automobile Motors—With a view to obtaining for small stationary motors as well as for automobile and boat motors the advantage of operating very economically with any one of a variety of cheap fuels, this advantage being at present possessed by the Diesel motors exclusively, Mr. A. Nougier, of Paris, proposes in *Le Génie Civil,* No. 17 of this year, to try preheating of the air charge as a substitute for the very high compressions employed under the Diesel system. His article is reproduced in German in *Gasmotorentechnik* for May and June, with a critical review promised for July. Nougier tries to show, first, that it is possible by preheating of the air and moderate compression to obtain a temperature at the end of the compression stroke sufficiently high to effect the ignition of the liquid fuel injected at that moment and yet not accompanied by the high pressure used in ordinary Diesel motors, in which compression alone is depended upon for producing the heat for ignition; secondly, that the expansion of the air which is caused by preheating, and which results in a reduced supply of oxygen to serve the combustion of the fuel, need not interfere with the success of the plan, and, thirdly, that the provision for preheating the air need not be too cumbersome, but can be managed within space limitations suitable even for automobiles.

In Diesel motors as now constructed a compression of 30 to 35 atmospheres produces a temperature of more than 500 degrees C., which suffices for igniting crude oil or even tar oil, but this high compression necessitates the installation of a separate air-compressor for injecting the fuel against the cylinder pressure, and this compressor, which of course must operate at more than 35 atmospheres in order to force the fuel in, not only absorbs about 7 per cent. of the motor's power, but renders an extremely expensive and heavy construction necessary in order to safeguard the tightness of pistons and valves. These drawbacks should, if possible, be removed.

THE PRINCIPLE OF PREHEATING

Air follows approximately the formulas for adiabatic compression, with 1 41 as exponent. These are:

(1) $$\frac{p_1 \times v_1}{T_1} = \frac{po \times v_0}{T_0}$$

(2) $$p_1 \times v_1^{1.41} = p_0 \times v_0^{1.41}$$

Equation 2 can also be written:

(3) $$p_1^{0.71} \times v_1 = p_0^{0.71} \times v_0$$

By dividing equation 1 by equation 2, there is obtained:

(4) $$T_1 = T_0 \left(\frac{v_0}{v_1}\right)^{0.41}$$

and by dividing equation 1 by equation 3, there is obtained:

(5) $$T_1 = T_0 \left(\frac{p_1}{p_0}\right)^{0.29}$$

In these equations $\frac{p_1}{p_0}$ stands for the pressure after compression divided by the pressure before compression: $\frac{v_0}{v_1}$ for the volume of the air after compression divided by the volume of the air before compression or, in other words, the compression ratio: T_0 for the absolute temperature before compression and T_1 for the temperature after compression.

From equations 4 and 5 the author draws a diagram from which the value of T_1 corresponding to different values of $\frac{v_0}{v_1}$, of $\frac{p_0}{p_1}$ and of T_0 may be read. The T_1 curves of this diagram are straight lines for any given value of $\frac{v_0}{v_1}$ or $\frac{p_1}{p_0}$. This diagram now gives interesting information bearing on the subject.

Usually it is air of about 15 degrees C. which is taken into a motor, but by contact with the hot cylinder walls this air reaches about 40 degrees during the compression, apart from the rise in temperature due to the compression itself. Assuming 40 degrees as the initial temperature, in accordance herewith, and a pressure ratio (p_1 divided by p_0) equalling 30, corresponding to the use of 30 atmospheres of compression in a Diesel motor, the diagram shows a value for T_1 of 566 degrees, and this agrees with thermometer readings from Diesel motor practice, thus confirming the diagram.

But the diagram shows also that the T_1 value obtained with a starting temperature of 40 degrees does not rise very fast by increased compression. With 50 atmospheres, for example, it reaches only 700 degrees. On the other hand, the same end-temperature can be reached with only 20 atmospheres of compression if the air is preheated to 80 degrees, or by 15 atmospheres and air preheated to 108 degrees. These examples show what advantages are within reach by preheating, if suitable arrangements are provided for heating the intake air by means of the exhaust gas without causing excessive counter-pressure against either the intake or the exhaust. And as the formulas, or the diagram, show that there is question only of raising the intaken air to a temperature of 100 degrees, at most 150 degrees, the practical difficulties do not *a priori* seem particularly forbidding.

The process in view is not comparable with the preheating system employed in automobile motors solely for the purpose of facilitating vaporization, as this preheating must be kept within very narrow limits in order to obviate premature ignition of the highly inflammable fuel.

Whatever reduction in the thermic efficiency is involved in the reduction of the compression contemplated by this method should be more than offset by better mechanical efficiency. The fuel injection, especially, would require much less power than with the high compressions.

Motors with 10 atmospheres of compression, preheating to 150 degrees and with a resulting temperature of 560 degrees available for the ignition of crude oil could be built in sizes as low as 30 horsepowers or less.

APPLICATION TO AUTOMOBILES.

It seems that automobile motors without carbureters or ignition devices, and to be operated with crude oil or naphtalene, could be built on this system. Regulation of the power by means of a good injector pump could be made more dependable than the present throttling system dealing with gases. As the ignition would not depend upon the maintenance of those proportions which produce an explosive mixture, the power development for a given motor speed or the motor speed for a given load might perhaps be extended over so wide a range that the change-gear mechanism could be dispensed with. In other words, a possibility of especial interest for the evolution of motor trucks is at hand by which the three most sensitive organs of the motor vehicle, the carbureter, the ignition device and the gear box, would make room for three more robust organs: namely, an injector pump, an injector and a preheating device, the latter also taking the place of the muffler.

THE LIMITS TO PREHEATING

The fact that heated air weighs less than an equal volume of cold air sets certain limits for the preheating method, since, for example, in the case of naphtha 1 pound of the fuel requires 15 pounds of air for effecting complete combustion, and in practice even a surplus above this figure because all the oxygen in the air does not get a chance at the fuel. The author shows by calculation that excessive preheating for this reason would, in fact, lead to incomplete combustion but also that air heated only to 100 to 150 degrees will afford a surplus of oxygen, although precautions may be necessary for limiting the heating when the motor is working under full load and the heating capacity of the exhaust gases is at its maximum.

A preheating arrangement is described shaped as a large muffler with tubular flues for the exhaust gases flowing in one direction and the intake air flowing in the opposite direction in the interstices, with baffle plates to obviate short-cuts and compel utilization of all the heat. Even when a motor runs idle and gives off comparatively cool exhaust gases it is necessary that the preheating should be so high that ignition is effected, and it is a question whether the gases can heat all the air which is required, under these circumstances. A 200-horsepower motor of a certain construction is mentioned whose exhaust, when it is operated at full load, reaches a temperature of 465 degrees, but only 135 degrees when it runs idle with its minimum of fuel. While these figures apply to operation with cold air intake, they indicate the difficulties. Such a motor requires 1,060 cubic meters of air per hour, and this at a temperature of 100 degrees would weigh 1,000 kilograms. The exhaust gas generated by the motor running idle, using only 10 kilograms of fuel per hour, would weigh 1010 kilograms. This, at a temperature of about 135 degrees is required to heat the 1000 kilograms of intake air to 100 degrees in a small fraction of a second. The author attempts to show what the areas of heating surface in the preheating device must be in order to comply with the needs and arrives at the result that it would be preferable to reduce the preheating to 80 degrees for operation under the throttle, which would still give 720 degrees final temperature for ignition and would make it easier to avoid overheating when running under full load. He figures that the preheater for these conditions should be only 1.06 meter long, 0.6 meter in diameter and provided with 100 flues of about 1½ millimeter diameter. The speed of the exhaust and of the intake air is figured at 19 meters per second, however, which seems high.—From *Gasmotorentechnik*, May and June.

—

Railway Motor Cars—While most early attempts at the employment of internal combustion motors for the propulsion of railway cars have been discontinued by reason of difficulties in adapting the change-gear mechanism to railway conditions, recent efforts looking to the use of Diesel motors in railway service are even more ambitious, in so far as the aim is no longer merely to supply a self-powered car for small sidelines and interurban traffic but actually to supplant the full-fledged steam locomotives. The Diesel two-cycle locomotive with cylinders of huge size disposed in V-arrangement is still on trial in Germany. It weighs 85 tons, develops 1,000 to 1,200 horsepower, looks like a steel passenger coach from the outside and runs with either end forward, the engine being located in the middle and the two ends nearly identical in the matter of access to control levers. Its construction has taken five years, as great difficulties were encountered in balancing the moving masses and providing for starting and maneuvering facilities by means of an auxiliary engine and two special air pumps. *The Engineer* of England tells of a somewhat similar enterprise undertaken by the Closed Circuit Air Transmission Company, Ltd. The power is furnished by a two-cycle Diesel motor, burning Texas oil, and the need which exists with all Diesel motors for a powerful air compressor is here exploited to make the compressed air serve not only for the starting and the injection of fuel but also for the transmission and regulation of the power delivered to the driving wheels of the locomotive. From the tanks brought under pressure the air is taken as needed into an air engine with double-acting cylinders, exactly as steam is taken from the boiler to a steam engine, and the locomotive is driven from this air-engine. The compressed air is heated by means of the exhaust gases from the motor before delivered to the engine and the air-cylinder exhaust is carried back to a reservoir to be recompressed with as great a saving of heat as practicable.—From *Auto-Technik*, June 14.

—

Porous Metal for Battery Grids—The scientific side of a recent invention by Prof. Hannover of the technological institute of Copenhagen, Denmark, was submitted to the French *Académie des Sciences* at its session on June 10. By taking advantage of the fact that one constituent of a metallic alloy in some instances solidifies more rapidly than another when passing from the molten state, Mr. Hannover has succeeded in expelling by industrial means the portions which remained liquid in half-molten plates of metal, using centrifugality as the active agency, and has obtained highly porous plates composed solely of the more resistent constituent in the alloy. He has for example thrown out antimony from an alloy of lead and antimony. The process is easier the lower the fusion point of the alloy. But a porous lead plate produced in this manner may be filled with copper or silver by electrolysis, and the lead may then be thrown out, leaving a porous copper or silver plate. The method has at once been applied to the production of grids for storage batteries, and these have an active surface five times greater than any which can be produced by mechanical means. They render it possible to either dispense with oxides, which are liable to be shaken off the plates unless expensive precautions are taken against this possibility, or to fill the porous plates with oxides, thereby greatly increasing the capacity of a battery. Batteries of this kind have been tested in the Danish government railway service, and the results are reported to have been very encouraging.—From *Die Automobil-Welt* and *Le Génie Civil*, June 22.

—

To Reduce Friction of Pistons—While the thermal efficiency of motors is the feature in their operation upon which most designers spend their best efforts, G. H. Tremolières, of Paris, has conceived a method of enhancing the mechanical efficiency through ample lubrication of the pistons. This, he claims, always results in better compression and increased power. He cuts three sharp-angled grooves circumferentially around the lower portion of the piston, and these act as troughs which, by reason of their location, are filled completely from the oil splash. Narrow grooves traced in the piston surface connect these troughs, and similar narrow grooves are traced upward to the grooves in which the piston rings are lodged. Only the topmost piston ring is isolated from this canalization system. The theory is that, as soon as the piston begins to descend, the oil in the troughs is compressed and forced upward through the canals, reaching all parts of the piston and piston ring surface with great regularity. The improvement is applied to old as well as to new motors.—From *La Pratique Automobile*, June 13.

Four-Speed Transmission

W. H. Cameron, S. A. E., Predicts Its General Adoption—Essential to Power, Economy and Flexibility of Control

Virtues of Four Speeds Graphically Illustrated by Diagrams and Tables

IT may sound strange to predict that the next radical change in automobile engineering will be the general adoption of the four forward speed transmission, but in my opinion it is bound to become generally used in all good American cars.

To-day it is found in this country only in the highest-priced cars; in fact, the cars selling under $3,000 that now have four speeds forward can be counted on the fingers of one hand. Abroad, where special reasons have forced the use of the four-speed transmission in the large majority of cars, its advantages are better understood.

One reason for its use on foreign cars is the extremely small bore of cylinders, due to the fact that the tax is graded by the size of the bore. An American car of more than 4-inch bore is in little demand in England, where a bore of 3 inches and a fraction is generally used with an extremely long stroke to give the maximum horsepower.

Under such conditions the four-speed transmission is positively essential, both to economize the power and to gain the required flexibility of control. Its use under these conditions, however, only serves to illustrate the actual money-saving in fuel and less strain upon the machine, as well as the advantages in driving which will come with the widespread adoption of the four-speed gear-box in America. For the same engineering principles apply in our case as in theirs.

Higher Gasoline—Lesser Bore

Before passing the point of economy, let me say I believe the tendency in America will be decidedly to smaller bore. This is due to the fact that everybody knows gasoline is becoming scarcer, and is sure to mount in price. I think the small bore is coming, even with the effort to popularize the six-cylinder car. The popular six-cylinder car of the future will be one with about the same piston displacement as the standard fours of the present.

The four-speed gearbox has been confined to high-priced cars in America, primarily because of its prohibitive cost. It means a complete change of design—more gears—wider gear centers—a big expense for the improvement, when all are totaled.

Motorists generally realize now that the life of a car depends upon its use and abuse. It does not take a car owner long to reason to the fact that making a car put forth every ounce of power on frequent grades is highly detrimental.

"Learn to control your car exclusively by the gas, as far as possible," says the instructor in motoring, to the school. The salesman says the same thing to the beginner. Everybody who gives advice on running a car says it, thereby admitting that something is wrong, or lacking in the transmission. Yet everybody realizes on a moment's reflection that the transmission is the logical first means for the control of the speed.

It takes long experience and special aptness—I may say genius—for driving to know just how far to throttle in regulating a car by gas. Few ever learn it perfectly. The driver who does it with any degree of skill knows his car like a human friend and brother, and is also guided by some sixth sense if intuition.

With the big majority this dependence almost entirely on the gas for regulating the car is a matter of guesswork. It is disastrous not only to the pocketbook but in not a few cases to human life. It costs money to pull the engine speed down until the car almost quits on high and then to race the engine to pick up on second, as is so commonly practised.

We have grown used to the sight of the driver on high gear, killing his motor at street crossings, street car tracks and railroad tracks, by throttling down before he can get his clutch out.

No. 1

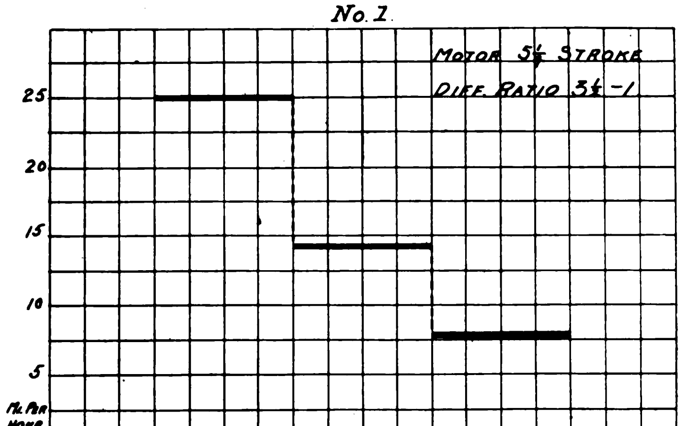

Fig. 1—Three-speed transmission. Note gap between second and high compared to the other

No. 2

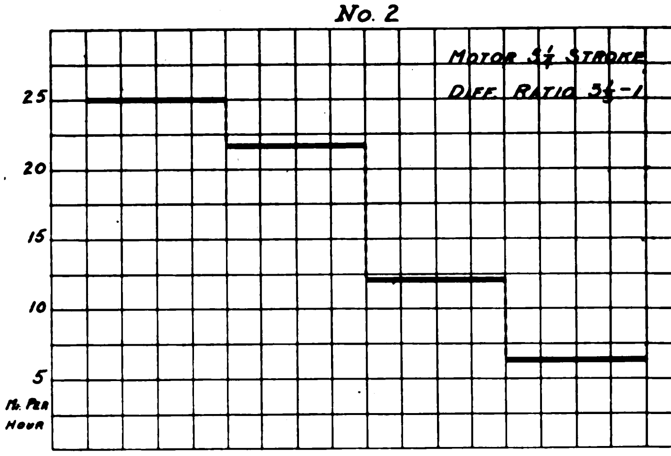

Fig. 2—Showing four-speed transmission, with the indirect fourth

If, instead, he slips into third speed on a proper four-speed transmission, he has a gear ratio which is practically the same as a 4½-to-1 rear axle—by having which, as anyone knows, the car can easily be throttled down to 2 or 3 miles an hour, and still pick up quickly.

By this time it should not be necessary to explain that the basic purpose of four-speed transmission is not to satisfy a mania for more speed. This was a common error when the four-speed transmission was rare practice. Four-speed transmission provides an efficient, feasible and logical control of the car—a control not based on guesswork, but upon an accurate, proved and dependable gearbox, built in accordance with universally acknowledged mechanical principles and in accordance with the best engineering practice the world over.

Four Speeds Easy on the Motor

It provides this control without wasting fuel, without racing the motor, and consequently with far less vibration. It relieves the motor of undue strain, especially in taking heavy grades. With four speeds (the direct drive being on the fourth) the long sand stretches, the heavy mud roads, the miles of axle-deep slush, the hills and mountains may be negotiated without fear of punishing the motor in the way that now works havoc and shortens by years the life of the best car built.

Unless one has actually driven with a four-speed transmission, he does not know the satisfaction and pleasure that it adds to driving. To those who have not tried it I would say: Make a test of two cars, one with a proper four-speed gearbox and the other with three speeds, both having the same topgear ratio, and thus having the same speed possibilities. You will be amazed at the difference in efficiency of control; the certainty of having just the speed you want when you want it; the reduction of the work of driving. You will never want to go back to a three-speed transmission.

Grade climbing is one of the problems most satisfactorily solved by the four-speed gearbox. Every motorist knows that unless he has an engine on which he can depend for a practically unlimited pull, he will find the inclination of many grades just a trifle too much for his top-speed. On such a grade, with a four-speed gearbox he can drop to third speed and it takes his car up like a bird. With a three-speed car he has to drop from top speed to second—and he makes an awful drop—in fact, almost 50 per cent. lower than high. If you have had this experience you know that resigned expression with which everybody settles back in the car to make the best of it until the car can be thrown into high gear.

The same condition is encountered in many roads which are just a little too heavy for top speed. The funeral pace then has to be taken on second speed, although the car is actually capable of much better speed on these roads.

We shall understand the necessity of the four-speed transmission more perfectly if we say that, while the speed ratios of a proper four-speed car are 1, 2, 3, 4 (the fourth being the top speed), the speed ratios of a three-speed car are really 1, 2, 4, the gap between second and high being so great that there is really no third speed. So when we put in a four-speed gearbox we are actually adding a third speed to the car.

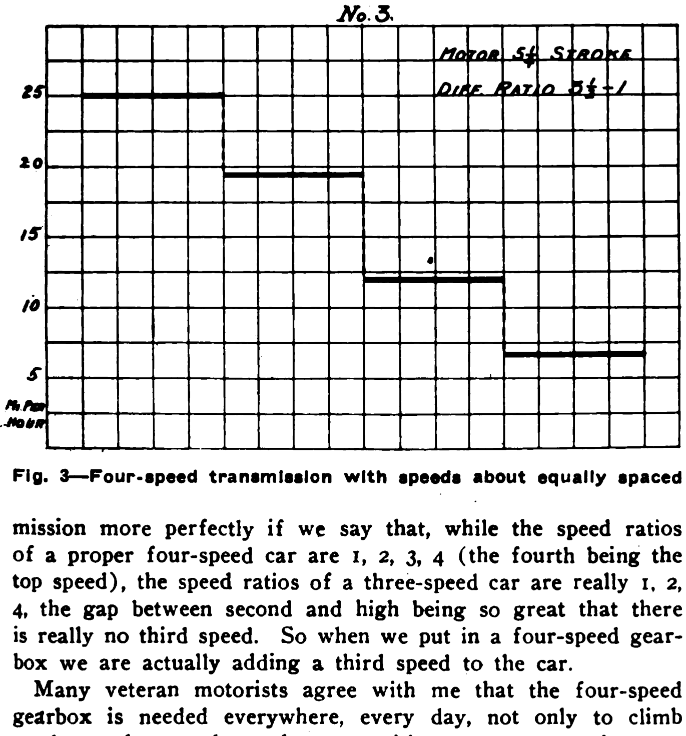

Fig. 3—Four-speed transmission with speeds about equally spaced

Many veteran motorists agree with me that the four-speed gearbox is needed everywhere, every day, not only to climb grades, and not only to do away with unnecessary engine racing, but to provide a really essential speed between second and high, where the gap now exists.

Types of Four-Speed Transmission

The greatest question in four-speed transmission is the ratios of gearing, or number of times the motor must turn over to the number of revolutions of the rear wheels. The subject has engaged the attention of the leading engineers in Europe and America for several years, but it is only lately that they have practically agreed as to the direct drive.

There are two types of four-speed transmissions: One direct on third speed, the other direct on fourth. The latter is generally conceded to be greatly in advance of the former. This is overwhelmingly proved by the practice on the great majority of cars now using the four-speed gearbox. Of 157 four-speed foreign cars, 132 have the direct drive on fourth. Of the American cars now using four speeds, 75 per cent. have the direct drive on the fourth. As the four-speed gearbox gains in favor, the indirect fourth will drop out overnight.

A study of the tables and diagrams shown herewith will enable the reader to see the difference at a glance. Table 1 shows a common three-speed transmission, which is about what is fitted to 85 per cent. of the three-speed cars. It will be noted that three and one-half rear axle gear ratio is used in all three tables. If the driver rushes his car at a hill on the high gear and has to change down, he goes to second, which is almost 50 per cent. lower than high. It will also be noted that in this transmission the first or low speed is only 11.20 to one. This is the reason that so many cars are forced to back over the stiffer grades if there is no other way round. The reverse, of course, is lower. This is the result of transmission design.

Take the next table, No. 2. It shows a transmission of a well-known and popular car. This is for the motorist who thinks he wants to burn up the roads, and who buys a car with an indirect fourth. He overlooks the fact that he loses almost all that he thinks he gains through the inefficiency of the gears, and has two speeds which are almost alike. It will also be noted that he has not much better second and low than his friend with the three-speed.

The ideal transmission, in my opinion, is shown in table No. 3. It will be seen that, when it is necessary to change from fourth to third, a speed is obtained which enables the car to go over the hill at a fairly good rate. The second in this is almost between the first and second of the others; consequently, if the car is fitted with a good clutch, the operation for all ordinary driving resolves itself down to a three-speed job (as the second can be used for starting on the level), leaving the extremely low first and reverse for emergency.

In the above I have but briefly outlined facts on which the judgment of the best engineers at home and abroad is based, in favor of four-speed transmission. Taking all these facts (and the showing of the tables and diagrams herewith) into intelligent consideration, everyone must realize that four speeds, with the direct drive on the fourth is the immediate step in the evolution of the leading cars.

Civilians for Britain's Motor Army

England is adopting new, up-to-date tactics in the management of her army. The latest thing is a scheme whereby civilians are to be enrolled in the special service as army motor car drivers. The department which takes them is known as the Special Reserve. This wing of the army comprises men who perform duties similar to those performed by them in civil life and needing no instruction as soldiers. The new reserve will consist of mechanical transport motor-car drivers for the army Special Corps, to be enlisted for 1 year at any age between 18 and 45, provided they are sound in health and measure 5 feet 3 inches in their boots.

Tells of Heavy Motor Frame; Wants Ignition Information; Best Oil for Clutch Leather; A Carbon Remover; Rules of the Road in New York; Two Tour Routes; Detecting Carbon; Asbestos for Windings

Likes a Heavy Motor Frame

EDITOR THE AUTOMOBILE:—A few weeks ago I noticed in THE AUTOMOBILE a description of a light motor frame with full directions as to its manufacture. In connection with this subject I would like to show you a frame which I have been using with great success for the last 2 years. It is a much larger affair than the frame described in your paper, but I think for a man in the repair business it would be superior because it is not necessary to bolt it down, and hence can be moved about the shop as desired. The cost of the frame is about $60, which is, of course, considerably more than what would have to be paid for that described. A sketch of this frame is shown in Fig. 1. The end view of the frame is shown at A and the elevation at B.

Rockville Center, N. Y. REPAIRER.

Troubled by Weak Spark

Editor THE AUTOMOBILE:—Some time back I think I saw the answer to the following question in THE AUTOMOBILE, but would like to ask a further explanation: How can a high-tension magneto be connected to run through a four-cylinder coil? And would it give a better spark? Would it do any harm to either magneto or coil?

I have a La Coste magneto and it does not deliver a strong enough spark with the throttle wide open, and consequently skips. If running the magneto through a coil will not cure the trouble, kindly tell me what will. Do you think it could be short-circuited?

Bridgeport, Conn. J. W. R.

—You cannot use your La Coste magneto in this way. It is already a high-tension instrument and hence cannot be put through another coil in the hope of increasing the intensity of the spark. The magnets probably need recharging or there is a short-circuit through several of the coil windings. Do not attempt to repair this yourself unless you have full facilities for doing complicated electric work. Send it back to the factory and you will find it cheaper in the end.

Which Is Better Clutch Oil?

Editor THE AUTOMOBILE:—Would you kindly tell me which is the better oil for softening the leather on a cone clutch? I have heard that neatsfoot and castor oil are both good, but I would like to know which is the better.

Hackensack, N. J. READER.

—You will find that neatsfoot oil is a little better for softening purposes than the castor oil, although they are both very good for this purpose. The main point to remember is to be sure to let the oil stand on the face of the clutch for at least 24 hours before again using the clutch, for, if this is not done, the oil will not get beneath the surface of the leather and will be wiped off the surface before it has a chance to soak in. In case the leather has become much glazed, the best thing to do is to renew it, as it will never regain its old usefulness.

Recipe for Carbon Remover

Editor THE AUTOMOBILE:—I secured the following formula for removing carbon from a man who claims to be a Detroit expert on the subject, and wish to know what THE AUTOMOBILE thinks of it:

Gasoline	1-2 gallon
Kerosene	1-2 gallon
Salt	2 drams
Cooking soda	2 drams
Aqua ammonia	4 ounces
Eagle concentrated lye	1 pound

I have also noticed in THE AUTOMOBILE a mention of acetone in connection with kerosene. Could this be used in one cylinder while the other three are running? Please tell me how to use the latter decarbonizer.

Boonville, Miss. L. D. RINEHART.

—The formula you give seems good, as the ingredients should all be effective. As a matter of fact, however, the secret of keeping the cylinders free from carbon is to give them constant attention instead of only at intervals. Many automobilists make a point of injecting about a tablespoonful of kerosene into each cylinder after they have returned from a run. The motor, being warm, transforms the kerosene into a vapor, and while in this state it is a very strong carbon solvent. If this is done consistently there should be no carbon troubles. Buy good lubricating oil and use the kerosene as mentioned above and you will not have any trouble at all.

In using the mixture of kerosene and acetone it can be applied in the same way as the kerosene alone, or it can be poured into one cylinder while the other three are left alone until the cylinder in which the acetone is placed is cleaned out and is again ready to fire. Do not put in more than a tablespoonful at a time, as, if you do, it will run past the cylinders too rapidly and get down into the oil supply, ruining its lubricating properties. Of course, it will be impossible to put the mixture into the cylinder while the motor is running.

By far the better way, in using a decarbonizer, is to remember the rule that a little at a time is much better than an enormous quantity all at once. If you will keep your oil supply normal, buy the best possible oil, inject one tablespoonful of kerosene into each cylinder after a run; your cylinders will always be clean and bright.

Wants State Rules of Road

Editor THE AUTOMOBILE:—Would be pleased to have you give me the rules of the road and the provision of Article 11 of the highway law of the state of New York through the "Letters Answered and Discussed" columns.

Eaton, N. Y. SIDNEY B. WESTCOTT.

—The New York state law as regards signaling and rules of the road is as follows: A person operating or driving a motor vehicle shall, on signal by raising the hand, from a person riding, leading or driving a horse or horses or other draught animal, bring such motor vehicle immediately to a stop, and, if traveling in the opposite direction, remain stationary for so long as may be reasonable to allow such horse or animal to pass, and, if traveling in the same direction, use reasonable caution in the act of passing such horse or animal; provided that, if such horse or animal appears badly frightened or the person operating such motor vehicle is signaled so to do, such person shall cause the motor of such vehicle to cease running so long as shall be reasonably necessary to prevent accident and insure the safety of others. In approaching or passing a car of a street railway which has been stopped to allow passengers to alight or embark, the operator of every motor vehicle shall slow down and if it be necessary for the safety of the public he shall bring said vehicle to a full stop. Upon approaching a pedestrian who is upon the traveled part of any highway and not upon a sidewalk, and upon approaching an intersecting highway or a curve or a corner in a highway where the operator's view is obstructed, every person operating a motor vehicle shall slow down and give a timely signal with his call, horn or other device for signaling.

The rules of the road are: Whenever a person operating a motor vehicle shall meet on a public highway any other person riding or driving a horse or horses or other draught animals or any other vehicle, shall seasonably turn same to the right of the center of such highway so as to pass without interference. Any such person so operating a motor vehicle shall, on overtaking any such horse, draught animal or other vehicle, pass on the left side thereof, and the rider or driver of such horse, draught animal or other vehicle shall, as soon as practicable, turn to the right so as to allow free passage on the left. Any such person so operating a motor vehicle shall, at the intersection of public highways, keep to the right of the intersection of the centers of such highways when turning to the right and pass to the right of such intersection when turning to the left.

A full copy of the laws of the state may be secured by application to Edward Lazansky, Secretary of State, Albany, N. Y.

From Yazoo City to Dayton

Editor THE AUTOMOBILE:—I am contemplating an automobile trip from Yazoo City, Miss., to Dayton, Ohio, *via* Memphis, Tennessee and Louisville, Ky. Will THE AUTOMOBILE give me the best route through Tennessee and Kentucky?

Yazoo City, Miss. A. S. GARDNER.

—The best route to follow through Tennessee and Kentucky would be after you have reached Memphis to take a sharp turn over to Tuscumbia, Ala., and thence up through Nashville, Bowling Green, Ky., Louisville, Lexington and Dayton. The roads from Memphis to Tuscumbia are fair to bad, the best way to proceed being by local direction through the following towns, asking in each town for the best route to the next: Germantown, Collierville, Moscow, La Grange, Grand Junction, Saulsbury, Essary Springs, Corinth, Burnsville, Iuka, Cherokee, Barton, Tuscumbia. From Tuscumbia to Nashville the same directions apply, the best method being to inquire from one town to the next, as the roads are in doubtful condition and definite information is scarce. The towns passed through are: Tuscumbia, Sheffield, Ala., Florence, St. Florian, Green Hill, Loretto, Tenn., Pleasant Point, Dunn, Lawrenceburg, Crestview, Williamsville, Sandy Hook, Ridley, Columbia, Brentwood and Nashville. From Nashville to Bowling Green is a direct route through Goodlettsville and Franklin. Continue on to Louisville by aid of local direction. From Louisville to Lexington you are on good pike road all the way. It is an easy road to follow, leading through Shelbyville, Peytona, Frankfort and into Lexington. From Lexington to Dayton the route lies direct through Cincinnati. From Lexington to Cincinnati is nearly all good macadam through Georgetown, Corinth, Williamstown, Crittenden, Covington and Cincinnati. From Cincinnati to Dayton is over level country and excellent gravel pike roads. Pass through Reading, Sharon, Pisgah, Mason, Lebanon, Ridgeville, Centerville and Dayton.

The information on the first part of the route is to say the least hazy and should be followed up closely by local inquiry. The motoring clubs, garagemen, etc., along the route will no doubt be able to direct you from town to town. The towns themselves you will know from the above directions. The route you will cover on your trip will be largely the same as that taken on the Glidden tour of 1910, so that additional light on the trip may be had from the stories of this tour in the press of that time if you have access to a file. There has been little change in conditions since then. The latter part of the route is over good roads and should offer you no difficulties.

From Washington to Washington

Editor THE AUTOMOBILE:—Noticing that THE AUTOMOBILE furnishes information regarding routes, I wish to have the following question answered: I intend to leave Washington, N. C., for a pleasure trip to Washington, D. C. I am entirely in ignorance as to which of the several routes will be the best for automobile travel. I should leave here, going to Raleigh, N. C., then to Winston-Salem, N. C., Roanoke, Va., Staunton, Va., into Washington. Or, I could go by the way of Weldon, N. C., Petersburg, Va., Richmond, Va., Alexandria, Va., and thence into Washington, D. C. Which of these two routes is the better?

Also tell me what are the requirements for licenses in the states which I will pass through, that is, North Carolina, Virginia, Maryland and the District of Columbia.

Washington, N. C. WILLIAM KNIGHT.

—It is difficult to state which of the two routes would be better. If you go *via* Roanoke there will be some very dangerous spots which it would be inadvisable to tackle unless you have the utmost faith in your car, while in the route *via* Richmond you will be up against some very bad dirt roads and, in many cases, mud-holes. With a good strong car that could be depended upon, the route *via* Roanoke would be better. You would pass through Raleigh, Durham, Stokesdale, Martinsville, Roanoke, Lexington, Staunton, Winchester, Washington. Some very good stretches of stone road are mixed in with fair to poor dirt roads; the latter predominate.

The requirements of the states for an automobilist passing through them are as follows:

North Carolina.................No fee for tourist licensed in own state.
Virginia.......................No fee for less than 8 days, twice a year.
Maryland.......................No fee for less than 8 days, twice a year.
District of Columbia..No fee for tourists licensed in own state. Register with Secretary of the Automobile Board, Washington, D. C., within 24 hours.

When Is a Motor Carbonized?

Editor THE AUTOMOBILE:—When a motor is badly carbonized, how can you tell it? What are the symptoms of this trouble? In other words, how can it be ascertained that it is time to remove the carbon from the cylinders? What is the best way of doing it? Is a mixture of kerosene and acetone as effective as hand-scraping?

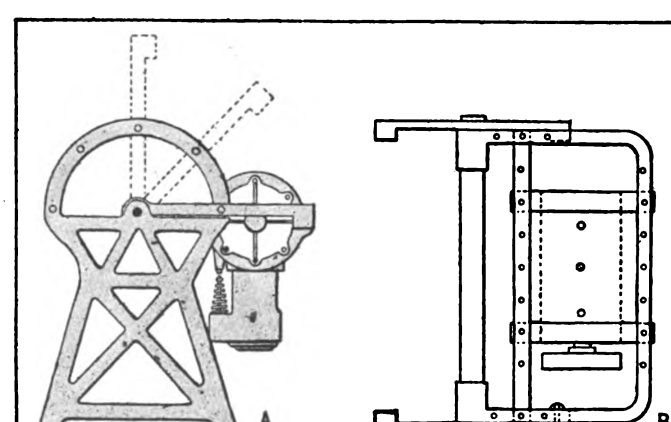

Fig. 1—Type of motor frame approved by repairman

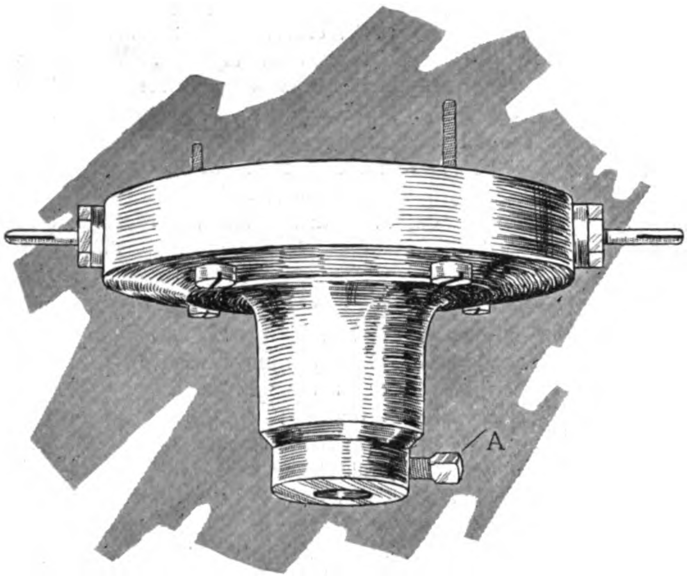

Fig. 2—La Coste timer, showing stud which holds shaft

(2) I have a rattle in my gearset which I think is caused by the teeth on one of the gears being slightly battered on one edge. Is there any way of remedying this without taking down the entire gearcase? My car is an Overland model 59.

(3) After my gas generator has been in operation a short time the gas tube fills up with water, causing the lights to flicker. What is a simple remedy for this?

East Canaan, Conn. D. C. Canfield.

—(1) Carbon troubles can be detected when they are far advanced by a knock in the motor due to preignition. A piece of glowing carbon will be hot enough to ignite the next charge when it is compressed to a degree less than that at which it is regularly fired. When ignited before dead center the charge will cause a knock, as it will act against the direction in which the piston is moving. A loss of compression is often caused by carbon. A flake of it will get under the seating of a valve and will not allow the valve to come down squarely on its seat and, as a result, a leak will be found. A decided falling off in power on the hills will indicate this condition. Misfiring is caused by carbon deposits on the electrodes of the spark-plugs. The current cannot jump the gap across the dirty points and, consequently, there is no spark. If the flake of carbon gets under the intake valve it will often cause backfiring into the intake manifold, which will be evidenced by the noise familiar to all automobilists. It is readily distinguished from the muffler explosion, as it is not nearly so loud. If the motor continues to run after the spark has been shut off you can be sure that your cylinder has a large deposit of carbon. The continued running of the motor, apparently without a spark, is from the same cause as the knock. That is, a glowing piece of carbon acts like an electric spark and causes the motor to keep on running. The most common method of dectecting advanced carbon troubles is by observing the knock and loss of power on hills due to reduced compression.

(2) This will depend on where the battered gear is and how it is battered. The probabilities are that there is something loose, as a bur would soon be worn off a tooth if it was causing a rattle. Lost motion between the teeth of two wheels will cause the trouble, as will also looseness on the shaft which holds the wheel. The gearset ought to be taken down and thoroughly examined, as it is very probable that the rattle is not the result of the battered tooth but of the same cause which made the tooth become battered. Look especially for worn bearing bushings.

(3) You are feeding too much water to your carbide. As you do not mention the make of the generator which you are using it is impossible to tell you how to cut down the amount of water. There is probably a key on the bottom of the generator with which you can accomplish this purpose. The jar of the moving car has probably loosened the key which controls the flow of water.

Another possibility is that you have a generator of the type in which some of the gas tubes pass through the water. If these tubes become leaky some of the gas gets into them, causing the trouble.

Suggests Asbestos for Winding

Editor The Automobile:—In your issue for January 15 I notice that you recommend a thin winding of hemp beneath the piston rings to tighten them when worn. Why not strips or threads of asbestos? I should think they would be better for this use, as there would be no danger of the hemp charring and burning under the heat of explosion. S. S. Ryan.

Fort DuPont, Del.

—The asbestos would undoubtedly be better for the purpose. The repair, however, is merely intended for use at such a time as when poor compression develops on a tour where it would be inconvenient to stop long enough to secure parts. Should the asbestos be at hand, it would be much better. Any thin gasket material would do if carefully applied.

Cylinders Fire Out of Time

Editor The Automobile:—Kindly shed some light upon the following matter: My ignition apparatus, a Kingston coil with La Coste timer, four-cylinder type, suddenly went wrong. The cylinders should fire 1-3-4-2. Instead, I suddenly found No. 2 cylinder firing while No. 1 vibrator spring was trembling, and so on with the other cylinders. Consequently the spark came one-quarter turn too late for each cylinder. The sparks did not occur when the piston had just reached the highest point but when it had gone, I judge, half-way. The motor stopped and ran feebly. What do you think is the matter with it?

Baltimore, Md. J. F. Ruppell.

—The trouble is that the timer has rotated on its shaft for a quarter turn, putting you one cylinder behind on your firing. As the piston is not in its correct position when the motor fires, hardly any power is developed. If you will look at the sketches of the La Coste timer shown in Figs. 2 and 3, it will be easy to understand the construction of the timer. A central shaft

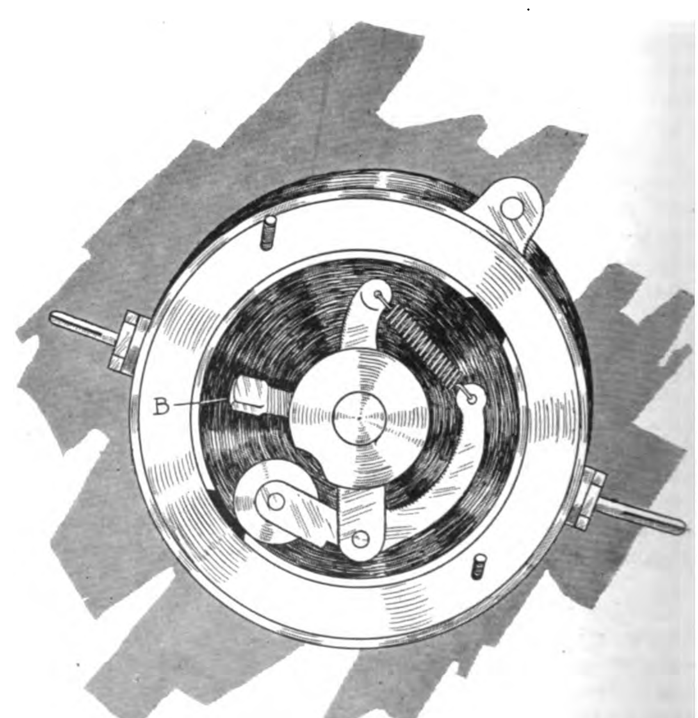

Fig. 3—Looking into La Coste timer with cover removed

runs through the timer casing and is held in its relative position to the sleeve of the casing by the setscrews A and B. The point at which the shaft has slipped around may be at either of these places, or it may be at both. Loosen the screws by turning them back to the left a full turn and turn the timer back in relation to the shaft until the roller will be in contact with the correct point when the vibrator is buzzing. It will probably be easy to find at which point the slip has taken place by trying both setscrews and determining which is the looser of the two. The looser one will show at which point the slip has occurred.

Has Trouble Meshing Gears

Editor THE AUTOMOBILE:—Would you kindly tell me why my car bothers me in the way of meshing gears? When running down-grade I often have to stop at the bottom of a hill before I can shift into low speed. My car is a Flanders 20 and has been run about 1,500 miles. FRED A. WOOD.

Burke, N. Y.

—That the trouble develops merely when going down-grade shows conclusively that in this case it is a matter of driving and not of any defect in the mechanism of the car. If you will accelerate your motor just a little before shifting you will have no trouble. The car, in going down-hill, has a tendency to go faster than the motor and, in order to get both gearwheels going at nearly the same speed, it is necessary to speed up the motor just before making the change. It is difficult to see any advantage in shifting to low speed at the bottom of a hill, but if you must, the above tip will help.

Wants License Information

Editor THE AUTOMOBILE:—Will you please let me know if a resident of Virginia is exempt from license in the states of Maryland, Pennsylvania, New York, Connecticut, Vermont, New Hampshire, Massachusetts, Delaware and Rhode Island?

I understand that New Jersey issues 8-day licenses for $1. Can these be obtained in New York City? S. W. H.

Norfolk, Va.

—As a licensed resident of Virginia you are free to pass through all the states that you mention above. In Delaware, Pennsylvania, Massachusetts and Rhode Island your time is limited, however, to a 10 days' stay, while in Maryland you may make two trips, neither of them to last more than 7 days.

You are mistaken regarding the New Jersey licenses. You can remain 15 days a year in New Jersey without taxation if you are licensed in Virginia. There are no more short-term licenses issued in New Jersey.

Lost Motion in the Rear Axle

Editor THE AUTOMOBILE:—I have an Overland 54 automobile and I want to know if it is practicable to take the lost motion out of the rear axle on the wheel end by closing the bearing sleeve and putting tin around it. The car has run 9,500 miles and the rear drive axles are worn pretty badly. I presume the sleeve and bearings are both worn. The bearings are Hyatt rollers. I would like to get the lost motion out without having to renew everything, drive axles, bearings and sleeves.

(2) Under proper use and normal lubrication, do you think that a rear axle which has been properly heat-treated should show any appreciable wear under 10,000 miles?

(3) How many pounds or ounces of soda should be put in the water to clean out a radiator on the above car? Or how much soda to each gallon of water? I have used a pound to each radiatorful. S. E. S.

Cobb, Ga.

—(1) There is no chance of making the repair good and lasting according to the method outlined by you. It is impracticable in the first place, because the bearings would be compelled to work in faulty alignment, which would soon cause them to wear worse than ever. The only thing you can do is to disassemble the parts and note which are worn and replace them by new ones.

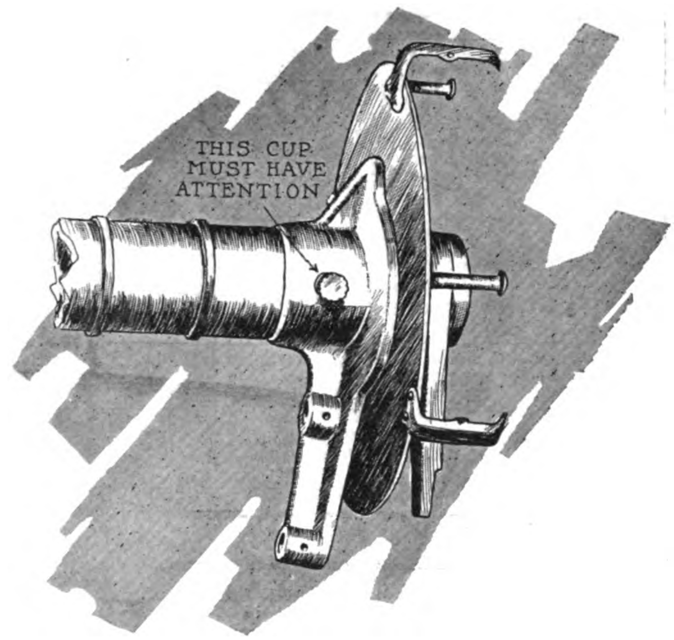

Fig. 4—Grease-cup on the Overland car axle

(2) A rear axle should not wear seriously in this length of time. The probabilities are that during the first thousand miles or so the lubrication was not as well taken care of as it should have been, and, as a result, the wear was started at that time. The grease-cup shown in Fig. 4 should be kept full of a good quality of lubricant and should be turned down every 200 miles. If this is neglected, wear on the parts you mention can be expected.

(3) You are using the correct amount of soda.

Wants to Make a Track Machine

Editor THE AUTOMOBILE:—I would like to know the name of a company which can furnish me with flanged wheels so as to convert an Oakland 40-horsepower car into a track machine. The gauge would have to be standard railroad gauge. Have you any data on a change of this kind?

Do you think it necessary to have a spring on steering rods so as to straighten wheels after rounding a curve?

Marble, Col. FRANK GERTIG.

—Such a wheel is made by Goodman & Company, of Bucyrus, O., who would be able to give you full data regarding the change. It would seem to be an advantage in having a spring to turn back the wheels after rounding a curve so that in case there is a tendency for one of the wheels to be out of line it would be corrected by the spring.

Gives a Tip on Vulcanizing

Editor THE AUTOMOBILE:—A good way of using an electric vulcanizer is to jack up the wheel, place the vulcanizer between the ground and the tire that is to be repaired and then slowly lower the jack until the desired pressure is obtained between the tire and the vulcanizer.

If the floor is of concrete it would be a good plan to place a board or some other insulator between the vulcanizer and the floor, because concrete conducts electricity and most electric light circuits are more or less grounded.

Allegheny, Pa. MURRY FAHNESTOCK.

—

[THE AUTOMOBILE is holding a few queries and communications which have been received unsigned. If a correspondent does not wish his name published it is merely necessary to state this fact in the letter and a *nom de plume* will be substituted. As an evidence of good faith, however, it is required that all communications be signed.—EDITOR.]

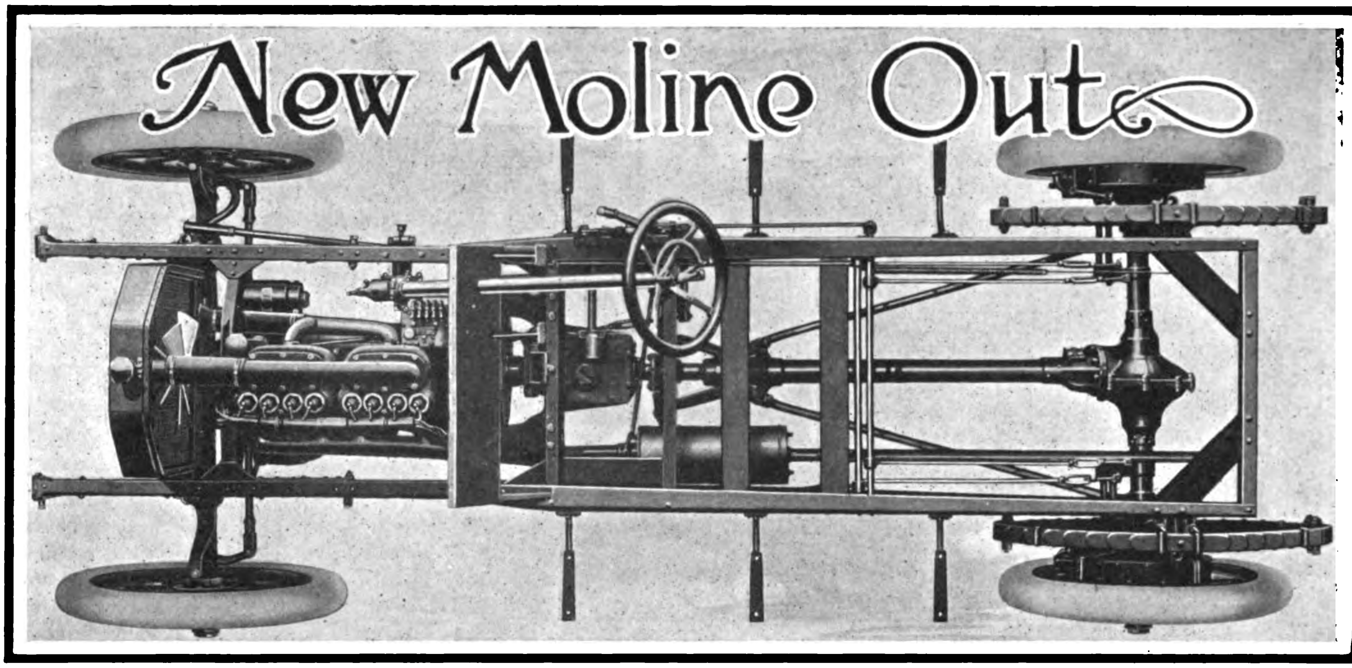

Fig. 1—Plan view of new Moline chassis, to be known as model M-40

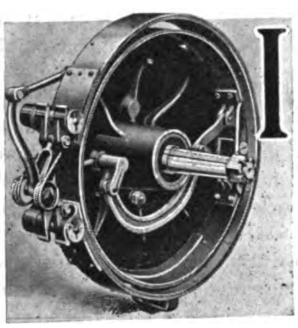

Fig. 2—Brake Interior

IN the 1913 Moline car, which is to be known as model M-40, there will be noted an increase in the bore of the cylinders, an increase in the wheelbase, a greater drop to the frame, gasoline tank placed on dash and the installation of the Ward-Leonard lighting system. These changes mark the introduction of the new model Moline. The car which has heretofore been distinguished by the fact that it had the greatest stroke-bore ratio of any of the American cars still remains among those having the greatest ratio, although it no longer has the highest.

The motor is rated by the makers at 40 horsepower, which should be conservative, considering the bore of 4 1-8 inches and the stroke of 6 inches. Last year the stroke was also 6 inches but the bore for the 1912 cars was only 4 inches, giving a stroke-bore ratio of 1.50 as against 1.45 for the 1913 cars. There are four cylinders cast in blocks of two each. The valves are all located on one side of the motor, the cylinder castings being of the L-head type. The valves, however, are fully inclosed. The motor is shown in Figs. 3 and 5. The inclosed valve construction is shown in Fig. 3, which illustrates the right side of the motor. The simple water manifold casting may also be seen in this view. In Fig. 5 the front and left side of the motor are shown. The carbureter is hung high, being 5 inches higher than last year, following the general 1913 practice in this respect that is tending to get everything where it may be reached by lifting the hood.

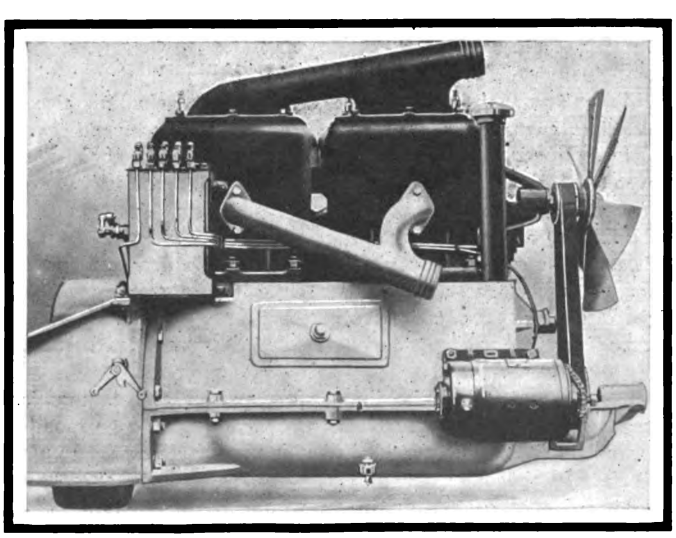

Fig. 3—Right side of the Moline long-stroke motor

Remarkably few projections are noted on the exterior of the crankcase, unit construction and what may be called a modified threepoint suspension being used. The front end of the motor is hung from a cross-frame which is bolted to arms at the top of the crankcase, as may be seen in the chassis view, Fig. 1. The rear of the crankcase is bolted to the clutch and gearset housing so securely that practically a single housing may be said to exist for the crankcase clutch and gearset. At the rear end of this housing a rigid connection is made to a heavy transverse sub-frame forming the other support for the motor as well as for the clutch and gearset.

The pistons are 4 3-4 inches in length and have four rings, the lowest of which is in the same plane as the center of the wrist pin. The other three rings are distributed evenly between the center of the wristpin and the top of the piston. From the center of the wristpin bearing to the center of the crank bearing the connecting-rods are 12 1-8 inches in length. The lower connecting-rod bearings are 2 1-4 inches in length and 1 3-4 inches in diameter. The wristpin bearings are 2 inches in length and 7-8 inch in diameter. There are three crankshaft bearings, all of which are babbitt-lined and of good length. At the flywheel end there is a 3-inch bearing. The diameter of the crankshaft is 1 3-4 inches.

Thermo-Syphon Cooling System

The cooling of the motor is effected by the thermo-syphon system. The manifolds are of large size and slope straight from the radiator to the waterjackets. The absence of a water pump leaves the designer free to place the magneto very close to the gear from which it is driven at the forward end of the motor. The magneto is of Splitdorf make, a double independent system of ignition being used. One set of spark-plugs is connected to this magneto while a second independent set of plugs is wired to a distributer, battery set and coil. Spark advance is controlled in the usual manner from a lever on a quadrant located on the steering wheel. Directly opposite the magneto on the other side of the motor is located the lighting dynamo. This is driven by a silent chain off the same wheel which drives the fan belt. The construction is shown in the front view of the motor, Fig. 5. As may be seen, there are no long shafts outside the crankcase, the absence of a water pump accounting for this. The installation of this dynamo is new this year and it has been accomplished in a way that takes but little room and has not altered the construction in any respect except to change the wheel from which the fan belt is driven. This should render it very easy for owners of previous Moline models to get the dynamo installed on their cars should they so desire. All six lights are taken care of by this installation.

The lubrication of the car is a combination of the force-feed and splash systems. The oil pump, which is driven from the camshaft, takes the oil from the crankcase reservoir and delivers it under pressure to the rear main bearing, the front main bearing, all four cylinders and the timing gears. After lubricating these points, the oil drains back to pans in the crankcase where the connecting-rods are allowed to dip in them for a very short distance, forming a spray which aids in the lubrication of the cylinders and also takes care of the central main bearing, the camshaft and the cam followers. After having reached a certain level in the crankcase the oil drains back into the lower part of the crankcase where the reservoir is located. There is a screen located between the reservoir proper and the oil pump through which all the oil passes on its course. None of the impurities gathered by the oil after having circulated through the system are allowed to pass into the pump.

Clutch Is Fitted with Cork Inserts

The clutch is a conventional leather-faced, cone type, situated in the flywheel, the diameter of which is 16 inches. In order to make the engagement easy and to safeguard the clutch against fierceness, cork inserts are used. The adjustment of the clutch spring is effected by means of a large nut located on the end of the shaft passing through the center of the male member of the clutch and also through the axis of the spring. Turning to the right increases the tension on this spring. Lubrication of the clutch is effected by a grease-cup located on the male member.

The gearset is of the three-speed type, working upon roller bearings throughout. The gearset housing is separated from the clutch housing by means of a stuffing-box; there being no passage of lubricant between the gearset and the clutch, thus guarding against oil reaching the face of the clutch and causing slipping. A similar stuffing-box with metallic packing is placed

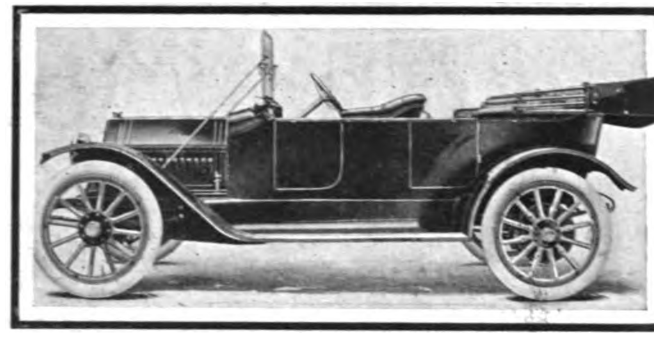

Fig. 4—The five-passenger touring Moline Dreadnought

at the other end of the gearset housing to prevent leakage in this direction.

The drive is taken up through a universal joint at the rear of the gearset and passes through a propeller shaft to the bevel gear rear axle which has been made larger. The front axle is of I-beam section and carries the wheels on large-size ball bearings. The brakes have been increased in size, being now 16 inches in diameter instead of 14 inches and the width is now 2 1-2 inches instead of 2 inches. The springs remain the same, being semi-elliptic front and scroll elliptic rear.

A radical change has been made in the gasoline system, two tanks being used The first is located in the dash and has a capacity of 8 gallons, while the other is under one of the front seats and has a capacity of 12 gallons. This arrangement allows the carbureter to be hung higher, as noted above.

Other features in this model which are worthy of note are: The marked increase in the wheelbase, 10 inches being added, which brings it up to 124 inches; to add to the easy riding qualities of the car, the upholstery has been deepened and Turkish back springs added; demountable rims are included in the regular equipment; right side control is retained but a change in the appearance of the car has been effected by leaving the toolbox off the runing-board and placing it under the floor of the tonneau.

Two styles of body are listed, a five-passenger touring car and a roadster. By making the tonneau of the five-passenger car very roomy it is made possible to fit auxiliary seats if desired. Both styles of body have fore-doors which are designed so that all of them can be opened. Any of the doors can be hooked ajar for purposes of ventilation.

In addition to the electric lighting system, comprising six lamps, dynamo and storage battery, the standard equipment includes a self-starter and a one-piece glass windshield.

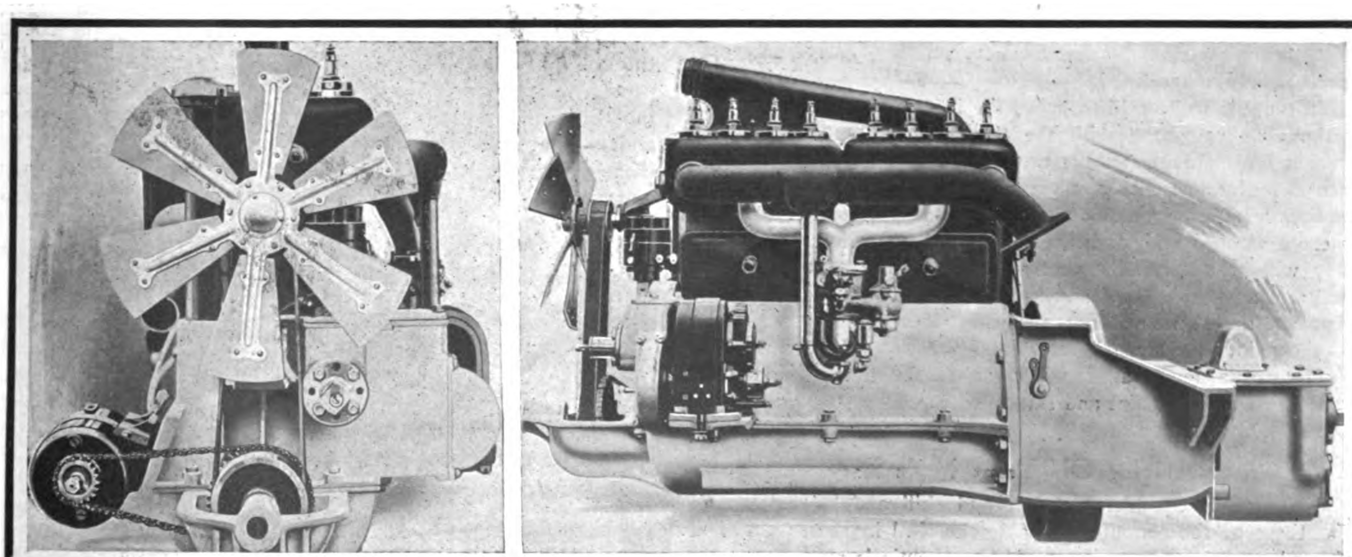

Fig. 5—Front and left view of motor employed in the Moline M-40 cars, showing lighting dynamo attached

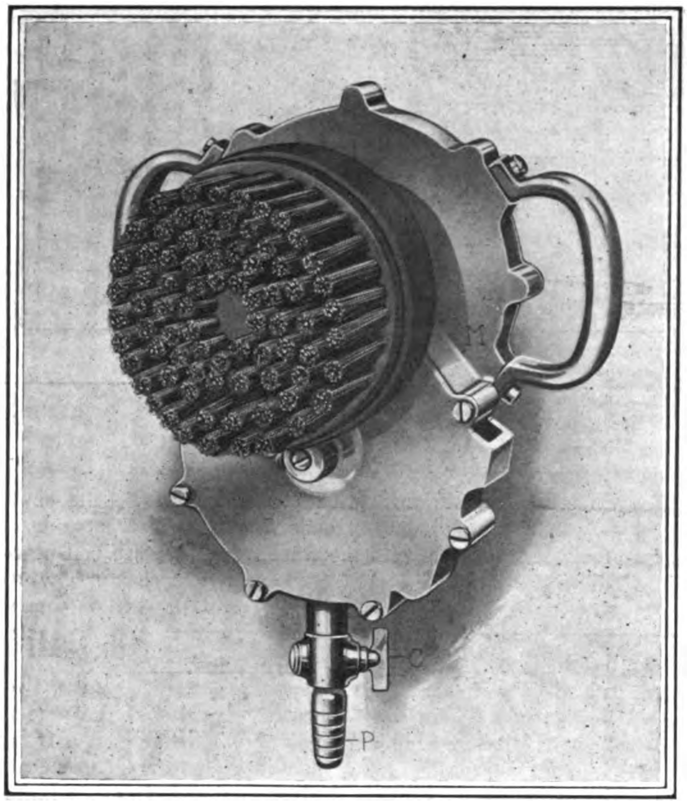

Fig. 1—Tough wire brush operated by compressed air motor

Removing Old Paint

Modern Practice Demonstrates Efficiency of Dissolving Coat With Chemicals Instead of Scraping or Burning

Liquid Can Be Applied by Compressed Air Method and Surface Cleaned by Vacuum Suction

CLEANING the body of the old paint before covering it with a new coat is a necessary and not too easy operation. There are several methods of accomplishing this end. These consist in either scratching or burning off the old paint, or removing it by the chemical action of a specially prepared paint-remover.

Little needs to be said to prove the inferiority of the first two methods as compared with the third one. The chance of a wooden body passing unhurt through the process of scratching, even if the utmost care is taken, is small. Burning off the paint requires a high degree of expertness on the part of the operator, where a wooden body is being worked upon, while even a metal body will be deformed except under adept treatment. Despite the great amount of care and skill required to do a good job by means of these two methods, the work of burning or scratching off the paint by no means completes the task of preparing the surface for a new coat, for it must still be cleaned of the remainder of the old paint and smoothed carefully so as to prepare it to take on a new coat.

Removing Old Paint Made Easy

All this takes considerable time and skill and by supplanting these by the action of suitable chemical ingredients a piece of hard work may be made easy. The chemicals must be able to dissolve the binder holding the paint to the surface coated with it, this binder consists, in practically all cases, of some sort of oil. Therefore, the chemical must dissolve the oil and thereby rob the color of its base, leaving it on the body surface "without a leg to stand on" and ready to be removed easily and quickly by suitable mechanical means.

One of the chemicals having the power of dissolving oil, and therefore of taking the paint off its base, is acetone. The principle of loosening the paint from the surface to which it was formerly applied is the same as that of loosening carbon deposits in cylinders from the walls to which they are held by baked products of decomposition of the cylinder oil.

Chemical varnish removal is a process which varies widely according to the appliances used in carrying it out. With suitable apparatus the work of cleaning surfaces can be done in a very short time and with an ease unknown to the great number of paint shop men.

Liquid Applied by Compressed Air

Among paint-removers, the product of the Wilson Remover Company, 30 Church street, New York, is characterized by its composition, which results, after application, in a thin and slippery mixture of solvent, paint, varnish and shellac. This does not stick to the surface, but may be easily removed therefrom. The remover comes in bottles and cans of various sizes and may be applied by hand where small articles are to be stripped of the paint covering them. In the case of large objects, such as automobile bodies, the automatic method illustrated in Fig. 2 will prove superior. This method uses a tank in which remover liquid is kept under the pressure of compressed air. A pipe, the open end of which is submerged in the remover liquid, extends through the wall of the vessel and there is fitted with a hose to the end of which a spray nozzle is attached. The compressed air may be supplied either from a tank or by pumping air into the vessel. If the valve governing the outflow of the liquid through the hose is opened, the air forces the remover through the hose and nozzle, where it is sprayed and mixed with air, the mist being directed against the surface to be cleaned of paint.

The remover striking the surface of the paint immediately begins to attack the oil which binds the color to the body sur-

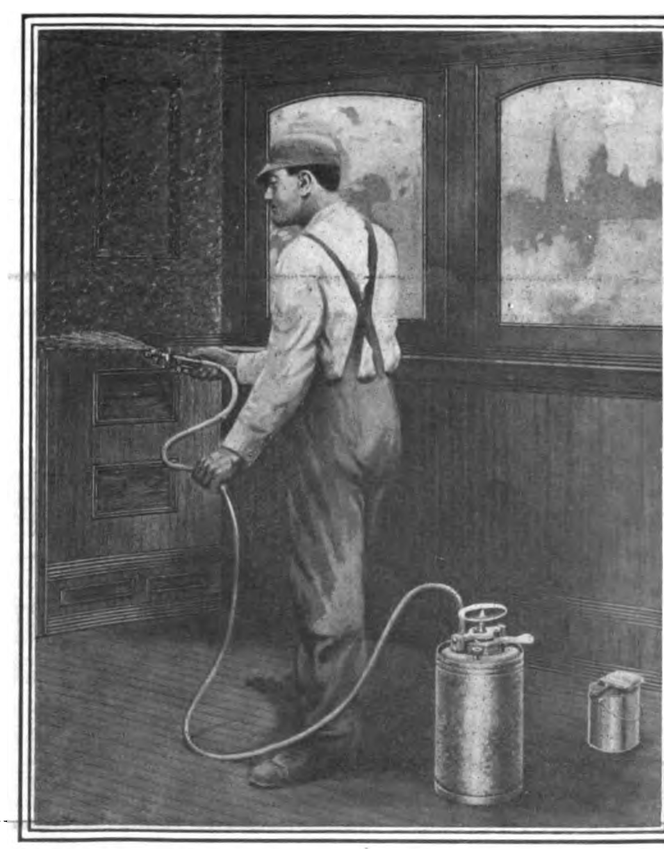

Fig. 2—Applying paint remover by compressed air through a nozzle

A car built for fording streams, when necessary, in the African colonies is tried out in a slip of the Seine

face and transforms it into a thin, jelly-like emulsion which may be removed by means of the motor brush, Fig. 2. The latter consists of a series of small wire brushes mounted on a holder which is carried by the shaft of a small compressed-air motor M. When compressed air is admitted through the pipe P, the pressure being regulated by means of the cock C, the brush holder is thrown into violent rotation and can be made to go as fast as 2,000 revolutions a minute. As the brush is rotated and moved along the surface which has been treated with the remover it sweeps off the gelatinous emulsion covering the body, rendering it ready for the immediate application of a new coat of paint.

Cleaning Surface by Vacuum Suction

Naturally, the use of paint remover and of the special accessories is not limited to the cleaning of automobile bodies; it may be used on any surfaces which are to be repainted, whether they are of wood, steel or aluminum. In some cases, especially where metal surfaces are being cleaned, the emulsion of remover, paint and varnish may be more advantageously taken off the surface by means of a vacuum suction cleaner, which is also operated by compressed air passing through a nozzle. This type of cleaner is specially suitable where a high-pressure air compressor is at hand and is even easier to manipulate than the brush, since it has no moving parts. Like the other appliances just described it is made by the Wilson Remover Company.

The process of paint and varnish removing described above marks one step toward the modernization of the painter's business, which has hitherto not been very up-to-date as far as standardization of effort and efficient, quick operations are concerned. As the tendency to get away from operations subject to the personal equation is growing in the automobile industry, there is hope that the paintshop, too, will be invaded by more efficient lines of practice and that, in not too remote a future, painting, like paint removing, will be done on a more or less machine-controlled basis.

—

To Lighten Metallic Construction—In an exhaustive analysis of the means for constructing as lightly as possible, G. L. Gerard, while referring especially to civil engineering, emphasizes a simple general principle which applies to automobiles as well and is sometimes ignored. It may be expressd: Avoid any design involving the use of parts which are not loaded to the chosen safety limit. For practical reasons, the underloaded parts usually have to be of the same dimensions as if they supported their share of stresses. This rule excludes parts which are mainly under bending stress. In many instances a saving can also be effected through the observation that the maximum stresses of different kinds to which a part may be subjected are never simultaneous.—From *La Technique Moderne*, issue of June 1.

An Amphibious Car

—

Charron Builds Automobile Specially Designed for Service in Africa Where Bridges Are Scarce

—

Interesting Method of Keeping Motor Going While Under Water—Details of the Test

—

IN THE European colonies in Africa bridges are not abundant, and the automobile which fords a little trickling stream in the sunlit morning is likely to find on its return trip in the afternoon a wide stretch of bottom land inundated with the drain from the adjacent veldt. It is for this condition, which may be duplicated in this country without going far away from the arteries of traffic, that the Charron firm of France has built a few vehicles capable of operating under water long enough to meet a travel-emergency. The illustration shows one of them emerging from the river Seine after a ducking. It is a shaft-driven car with only 10 inch clearance under the front axle, though chain-drive and more ample clearance would evidently be better for rough colonial travel. The provisions for keeping the motor going under water are more interesting, though it should be mentioned that the cone clutch has given no trouble. The exhaust pipe is prolonged by means of a hose and tube turned upward at the rear of the car and secured in that position, so as to have the burnt gases escape into air, as shown in the pictures. This extension pipe is only attached when needed. The magneto is enclosed in a tight steel casing. In the monobloc motor with valves on one side the spark plugs are screwed into the admission valve housings and are covered with an inverted sheet steel gutter secured by a tight joint to the cylinder block. A tube containing the wires connects the gutter with the magneto housing. The carbureter is encased in the same manner as the magneto, and a tube is raised from this casing to the atmosphere, extending to the height of the driver's face. The air vents of the crankcase are corked up when the car goes into water, and it has been found that this provision causes no inconvenience in the operation of a four-cylinder motor in which the volume of air space in the crankcase is not affected materially be the piston movements. On the other hand it has been found necessary that the compression should be irreproachable, so that no pressure from the burnt gases shall find its way to the crankcase and accumulate there.—From *La Vie Automobile*, June 22.

—

The latest estimate as to the world's product of gasoline is at the rate of 2,000,000,000 gallons per year.

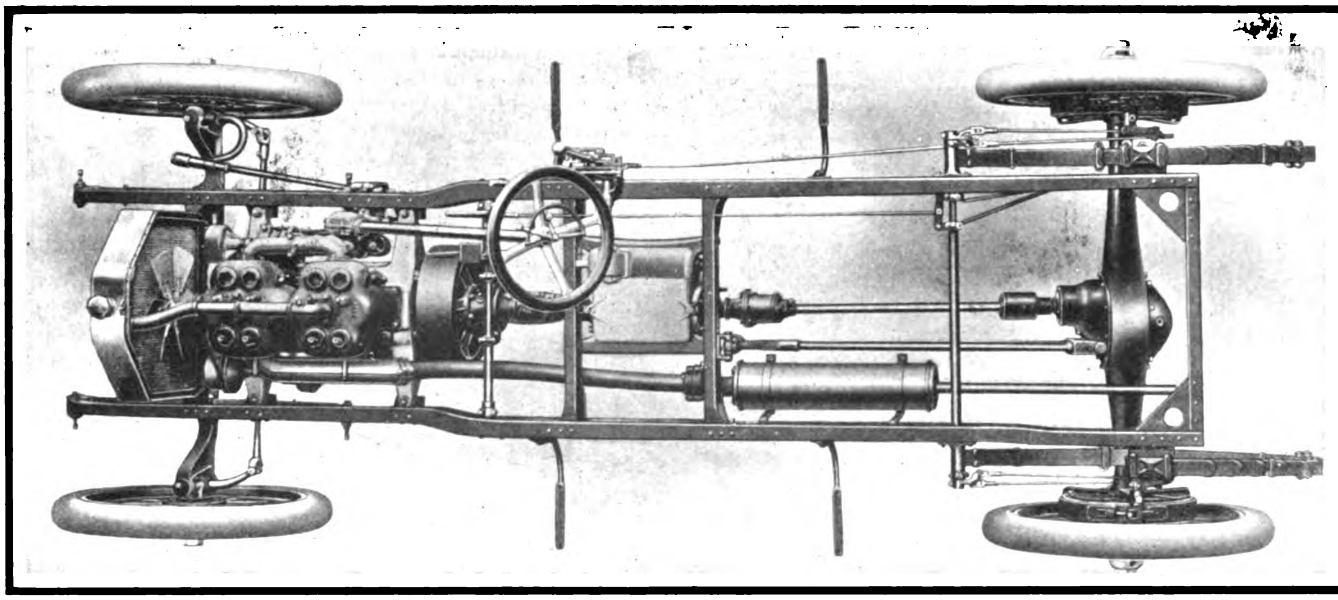

Fig. 1—Chassis of the Pullman model 4-44, embodying the improvements adopted on the 1913 line

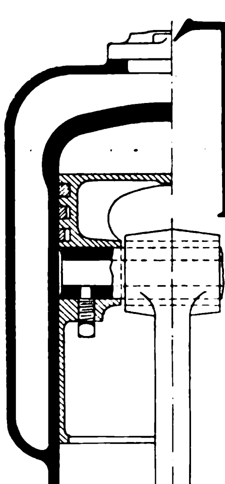
Three Pullmans

Company's Line for 1913 Will Include Two Four-Cylinder and One Six-Cylinder Models

Easy-Riding Qualities Enhanced—Silence of Operation Secured by Superior Workmanship



Section through motor, 4-44

THREE models of Pullman automobiles will be on the market for 1913. They will be known as the 4-36, 4-44 and 6-66. The first number in each case refers to the number of cylinders, while the second refers to the rated horsepower. There were four models built under the 1912 date and these were known as models 4-30, 4-40, 4-50 and 6-60. The 4-50 has been dropped for 1913 as a regular model and the other three have been continued with modifications, but under the new names just mentioned. The principal changes which will be noted in the new line of cars seem to follow very closely along the lines of the trend in modern automobile engineering practice. Better materials and greater accuracy in manufacture are the keynotes, giving a product that each year takes a step in the direction of ultimate perfection. Greater comfort for the driver and the passengers is also made an aim, as is shown by the greater ease of control and increase in easy-riding qualities.

For all three models the following changes will be noted: Larger radiators, lighter wrist pins, dash carbureter primer for easy starting purposes, larger steering wheel and longer spings both front and rear. Besides these changes there are several others which have been made on the two larger cars only, that is the 4-44 and the 6-66. A new crankcase bottom pan has been added to these two models, giving an increased oil supply; an extra bearing has been added to the camshaft, pump and magneto shafts, giving a stiffer support and reducing wear. This has been accomplished by altering the shape of the timing gear case to make it support the extra bearing. An arrangement is added whereby the level of the oil in the crankcase is under the control of the driver from his seat, a regulating device having been placed on the dash. A larger flywheel has been placed on both these models, an increase of diameter of 2 inches having been made. The gearset has been entirely redesigned and an extra bearing added to the dog clutch. An electric lighting generator driven by chain is also a feature of both cars, while on the 6-66 alone there are embossed yokes on the rear wheels.

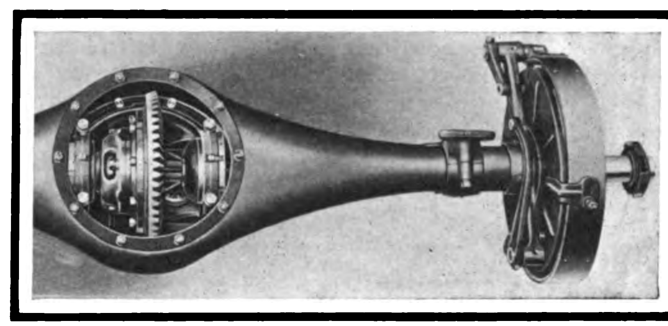


Fig. 2—Rear axle and brake with differential cover plate removed

Motor Parts Interchangeable

The motors on all cars have cylinders cast in blocks of two. The only difference between the six-cylinder car and the larger of the two four-cylinders is that the six-cylinder has an extra block of two cylinders and of course has the necessary added features of a six-cylinder car. The bore and stroke are the same, and throughout wherever it has been possible the parts of the two motors are interchangeable. This is true throughout the Pullman line. The interchangeability of parts has been made a feature, so that manufacturing costs, which are always high where several models are made, have been reduced to a minimum. The valves throughout all the motors for instance are the same both for the exhaust and intake sides. They are all 2 1-8 inches in diameter and have a lift of 5-16 inch. The bore and stroke of the 4-36 are 4 1-16 and 5 inches, respectively, and for the 4-44 and 6-66 the dimensions are 4 1-2 by 5 1-2 inches. The horsepower rating on all models is taken at 1300 revolutions per minute.

All motors are of the T-head type with the valves enclosed. Cover plates are fitted over the valve mechanism on the sides, preventing leakage of lubricant and giving a neat appearance. The material of the valves is nickel steel for the heads, while the stems are made from machine steel. The joint between the head and stem is made by the electric welding process. The pistons are made of the same grade of gray iron as the cylinders and are ground with a taper at the top, while from the lowest ring down they are straight-sided. The pistons and cylinders are hand-lapped after assembling on all models to secure the best possible fit. The compression on all models is about 60 pounds to the square inch. The connecting rods are I-beam in section and on the two larger models 11 3-4 inches in length.

Splash Lubrication Employed

The motors are lubricated by splash. On the two larger models the oil is delivered from an eccentric pump which is driven by spiral gears from the camshaft to the oil troughs and also to the timing gears in the front of the case. The oil is splashed to all the bearings by the lower end of the connecting rods, which dip far enough into the oil contained in the troughs below the throw of each to create a spray which pervades the entire crankcase and takes care of the cylinders as well as all the bearings contained within the crankcase. After the camshaft, crankshaft and timing gears have been lubricated, the excess oil flows back through drains into the oil reservoir, which is located in the bottom pan or lower part of the crankcase.

The dash adjustment feature, which is prominent on the 1913 Pullman cars, allows the driver to change the point at which the overflow from the upper to the lower part of the crankcase takes place. The oil pump continually delivers oil faster than it is used and the oil is kept up to the level of the hole in the drain. The part containing the drain hole can be raised and lowered by the device shown in Figs. 6 and 7, thus enabling the driver to supply more oil on a stiff pull than would be necessary on ordinary straight roads or city work. The redesigned crankcase of the 4-44 and the 6-66 has brought the oil-carrying capacities of these two up to 1 1-2 and 2 1-2 gallons, respectively. The oil capacity of the 4-36 is 2 gallons.

The oiling system of the 4-36 is very much the same as that employed on the two models just described. The oil overflow can be controlled, but not from the dash. The control in this case is effected by lifting the hood and manipulating the lever which is located on the upper side of the crankcase. Another distinction is that there is no oil lead to the timing gearcase on the 4-36. The timing gears are lubricated by grease in this model.

The cooling system remains unchanged since last year. On all models a centrifugal pump is employed which is positively driven by gear from the crankshaft. The width of the waterjacket is 5-8 inch around the cylinders and the thickness of the metal in the jacket is 3-16 inch. The metal in the cylinder is thickened at the combustion space so that an increased width in the waterjacket is necessitated by it. From 1-4 inch on the walls the thickness bulges out at the combustion chamber to 3-8 inch. This gives an added strength at this important part, but renders the cooling duties of the jacket more difficult, a situation which is met in the Pullman cars by a corresponding increase of sectional jacket area on the cylinder head.

Better material is a feature in the building of the engine. Instead of the ordinary chrome steel, nickel steel bolts are being used throughout the motor on the 1913 cars. All the shafts are ground with a limit of tolerance of .00025 inch. This limit is strictly adhered to in the case of all the shafts and pins, blocks and bearings of the universal joints. Formerly a plain finish was used on many of these parts, mere machine work being made to suffice where grinding is now required by the maker's specifications. Interchangeability here also finds a field, for the cam contours are the same for all models. A rounded form of cam is used, giving a fairly quick opening and closing without the shock, side thrust and consequent wear of the square-sided cam.

Accuracy to Insure Silence

No special means of insuring silence have been taken beyond good workmanship. It is the belief of the engineers of the company that where accurate workmanship is made a study, silence will come of itself. All the proven methods of construction have been incorporated. In the timing gearset spiral gears are used which are especially hardened through a heat-treating process given them at the Pullman factory. The gears are of the spiral type and are cut slightly below the finished pitch, the heat-treating process being of such a nature that after completion the gears have expanded slightly. In order that the

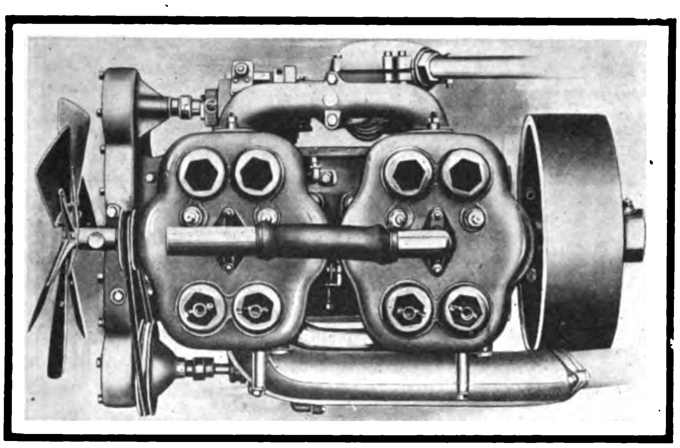

Fig. 3—Looking down on top of the 4-44 Pullman motor

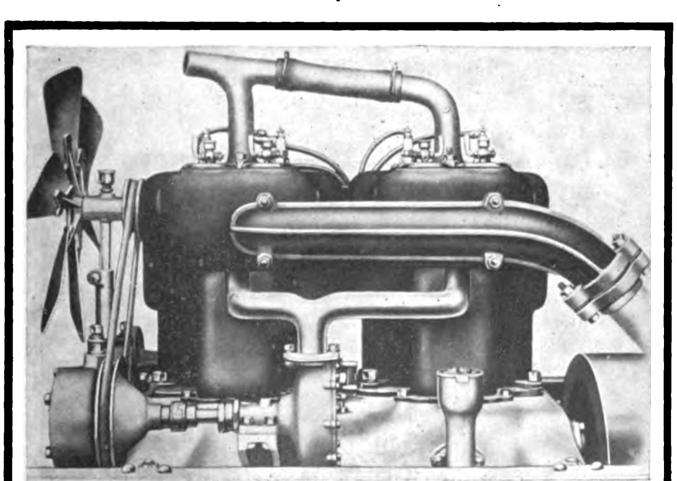

Fig. 4—Left side of motor, showing arrangement of manifolds

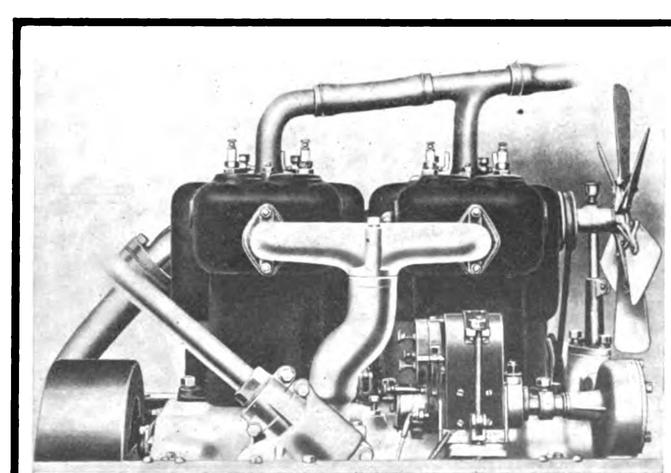

Fig. 5—Right side of the same motor, showing magneto and intake

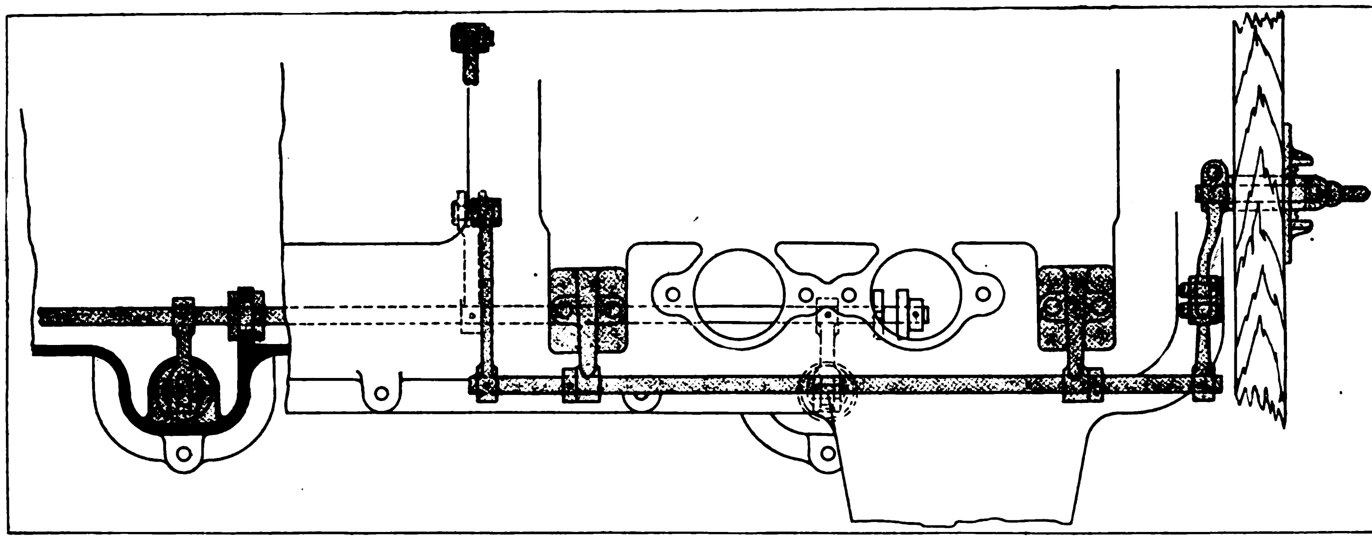

Fig. 6—Plan view of the new oil level adjusting device fitted to the model 4-44 and 6-66 Pullman cars for 1913

gears do not lose their shape while passing through the heat treatment they are packed in a sandy compound and enclosed in a cast iron air-tight case. They are given a permanent set in this treatment and can then be given the oil treatment without danger of warping under the internal stresses due to the heat.

The ignition system is the Bosch dual on all three models. The magnet is driven by a short independent shaft and is located on the opposite side of the motor from the water pump. The gasoline system remains the same as last year, there being no change in the tank capacities. The smallest car, the model 4-36, can carry 15 gallons of gasoline; the 4-44 has a capacity of 18 gallons and the 6-66 has a tank which will carry 25 gallons. Figures on fuel economy have not been compiled officially, but on a quick trip from the factory in York, Pa., to Washington, D. C., and back not long ago one of the factory testers averaged 12 miles to the gallon with the six-cylinder car. The other models would of course give a higher mileage to the gallon.

The clutch fitted on all models is the leather-faced cone type. It is not enclosed, as the aluminum crankcase of the motor stops at the flywheel. In order that there shall be no leakage of oil around the crankshaft bearing at the rear of the crankcase and no possibility of the clutch becoming oily from this source there is a ring on the end of the crankshaft which catches the oil and throws it by centrifugal force back into the lower part of the crankcase. Behind the ring there is a felt washer to still further protect the end bearing against a leakage of oil. The crankshaft ends in a broad flange to which is bolted the flywheel by means of nickel steel bolts with castellated nuts. The flywheel member of the clutch is of cast iron and has a diameter on the two larger models of 18 3-4 inches as against 16 3-4 inches last year. The engaging member of the clutch is of aluminum with a face width of 3 inches and a mean diameter around the center of the frustum of the cone of 15 3-4 inches. This gives a frictional area of approximately 144 square inches at the clutch and should be ample for any kind of service. Beneath the surface of the leather there is a series of spiral springs which have the feature of being adjustable, as they are fitted on a through bolt which is held at the rear by a nut and lock nut, as is shown in the sectional view of the clutch in Fig. 8. The main clutch spring is adjustable for tension and is contained in a housing surrounding the short shaft on the aluminum engaging member of the clutch. The adjustments for tension on the spring are made by taking up on a stud which enters the shaft fixed to the flywheel member of the clutch. A ball thrust relieves the washer on the end of this stud and permits of its being turned when it becomes necessary to make the adjustment. A drain plug is located on the lower part of the housing which surrounds the clutch spring. Should any oil collect in this housing it may be drained off without trouble by means of this plug.

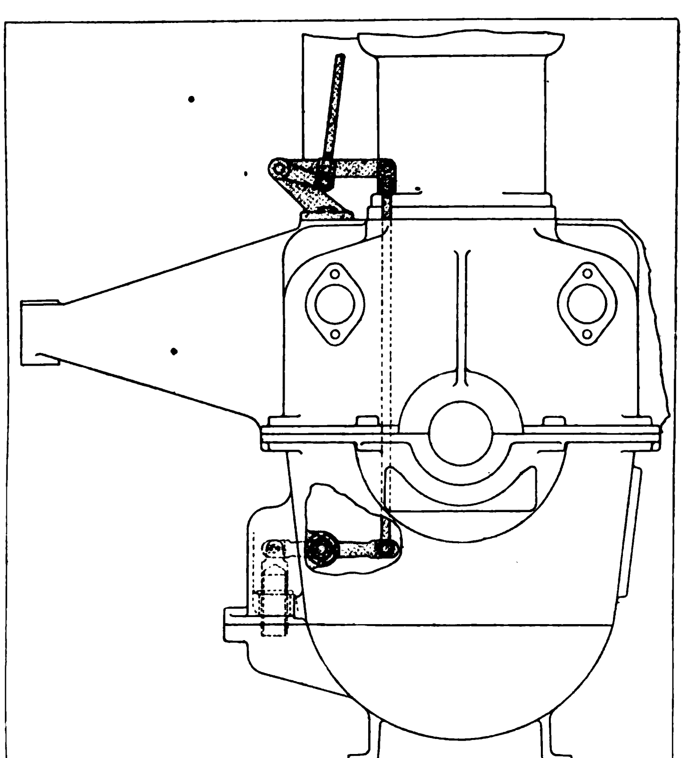

Fig. 7—End view of motor crankcase showing adjusting device

Details of the Transmission

The gearset of the 4-36 is capable of three forward speeds and one reverse, while the 4-44 and the 6-66 have four forward speeds and reverse with direct drive on third speed. The shifting shaft of the gearset is of the four spline type, while all the moving shafts are carried on annular ball bearings. A clearance of .005 inch is allowed in the gearset for easy meshing, but every part is carefully ground to size so that there is no lost motion in any part of the gearbox. Silence in this important part of the car has been striven for by the use of the best alloy steel and careful fitting. The distance between bearings in the 4-36 model from inside to inside is 7 1-2 inches, while in the 4-44 and the 6-66 this distance is 11 3-8 inches. The drive passes through a 3 1-2 per cent. nickel steel driving shaft into a Timken rear axle on the two larger models, while on the smaller model the axle is made by the Standard Roller Bearing Company. The gear reductions on the different models vary. On the model 4-36 the reduction is 3 1-4 to 3 3-4 to 1; on the 4-44 it is 3 to 3 3-4 to 1 and on the 6-66 it is 3 to 3 1-2 to 1. Pressed steel housings are used on the rear axle and the bearings are tapered roller in the case of the larger model and annular ball in the smaller.

The brakes consist of two separate sets on all three models. The outfit on the 4-36 is made up of a set of internal expanding metal-shod brakes and a set of external contracting brakes with a Thermoid lining. The brake drum is 14 inches in diameter and the width of the drum is 2 inches. The service brakes are operated by pedal and the emergency brakes in the usual manner by a lever at the side of the driver. The brakes on the 4-44 are exactly similar except that the dimensions of the brake drum are different, having a diameter of 16 inches and a face width of 2 1-4 inches. The brakes on the 6-66 are also of the above description, but have a 17-inch diameter and a 2 1-2-inch width of face.

The wheels on all the Pullman models are the ten-spoked artillery type all around. On the model 36 they are 34 inches in diameter, on the 4-44 and 6-66 they are 36 inches in diameter.

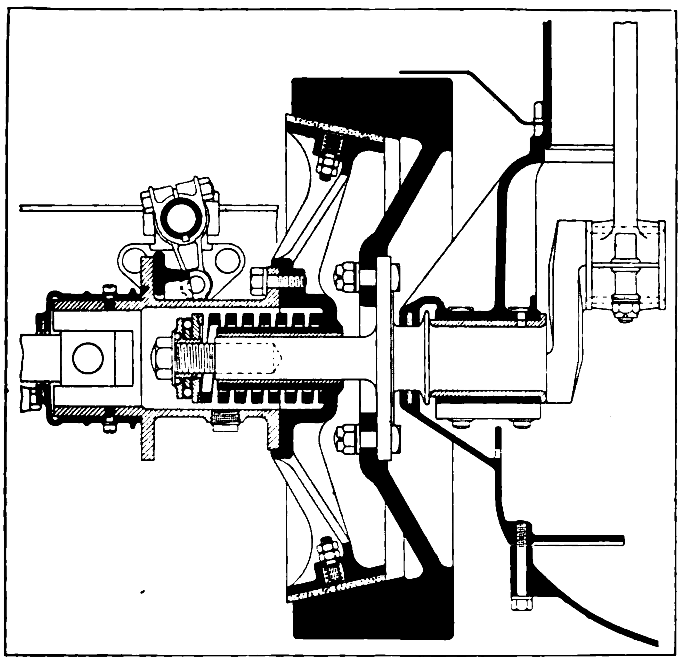

Fig. 8—Sectional view through the leather-faced cone clutch

They are all fitted with Universal quick detachable demountable rims and on the four-cylinder cars with 4-inch tires. On the six-cylinder car the tire equipment is 4 1-2 inches front and rear. The front wheels on the 4-36 run on ball bearings, while on the two larger cars the bearings of the front wheels are of the tapered roller type.

The steering gear and control are on the right side of the car.

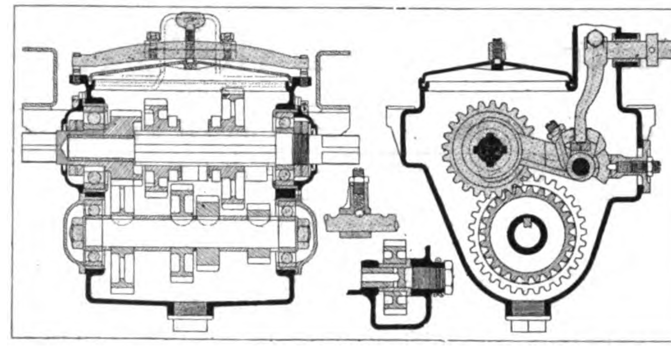

Fig. 9—Gearset of Pullman 4-36, transverse and longitudinal views

The Pullman company has not made any changes in this direction and all the cars are so equipped. The steering gear on all cars is a worm and sector of the semi-irreversible type. The steering knuckles are of the Elliott type. Another feature of all types of Pullman cars is the increased size of the steering wheels. They are now respectively 18 and 19 inches in diameter, the first figure applying to the two four-cylinder cars and the second relating to the six-cylinder.

Suspension, Body and Equipment

The frame is of channel section and is of pressed material. The motor is hung by four brackets which are deep enough to give the required stiffness. The springs are all semi-elliptic in front and 3-4 elliptic rear. The present length of these is considerably in excess of what it was in the 1912 models. The lengths are now as follows: On the 4-36, 40 inches front and 47 inches rear; 4-44, 40 inches front and 47 inches rear, and for the 6-66, 42 inches in front and 54 inches rear.

The bodies are also manufactured at the Pullman plant and are made of metal and wood. The regular body on the 4-36 is a five-passenger fore-door touring car, but on request any other type of body that the purchaser desires will be made and prices quoted on same. On the 4-44 the regular body is also a five-passenger fore-door touring car. The 6-66 has for its regular equipment a body of seven-passenger capacity, but it is also subject to the buyer's wishes in the matter of body style. The tread on all the cars is 56 inches and the wheelbases are 118, 122 and 138 inches for the 4-36, 4-44 and 6-66, respectively.

The equipment for the 6-66 model includes a self-starter which is generally of the Ever-Ready type, although other styles may be fitted by agreement with the manufacturers. A complete electric lighting outfit is also included, along with top, top boot, windshield, speedometer, horn, tools, tool box, robe, coat and foot rails, pump, jack, repair kit, portable electric vulcanizer, tire irons and quick detachable rims. For the 4-44 the same equipment minus the vulcanizer is offered, while for the 4-36 the lighting outfit is adapted for gas.

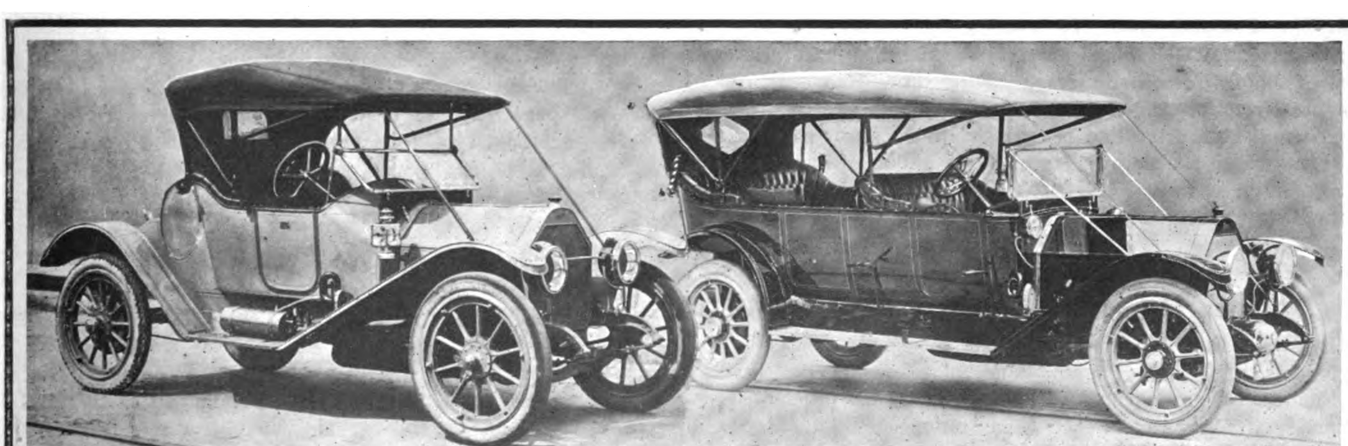

Fig. 10—Pullman Speedster 4-44 and the seven-passenger touring car which is standard on the 6-66 chassis

Late News of the Trade

Ford Company Has Purchased an Entire Block in San Francisco for Its Coast Factory

SAN FRANCISCO, July 13—A block in San Francisco has recently been purchased by the Ford Motor Car Company as a site for its Pacific Coast factory. The move is regarded as one of the most significant in local automobile circles in recent years as this is the first assembling plant of any auto company on the Coast.

As soon as practical a re-enforced concrete building of three or four stories will be erected for the factory. It is generally understood that the new plant will be used entirely for assembling, but it has been persistently rumored that the company intends to make this San Francisco branch as a distinct unit in the manufacturing of the Ford machine. A representative of the company in this city declares that the plant will be used solely as an auxiliary for the Eastern factory, which is already overtaxed, chiefly for the assembling and distributing of machines.

The site selected is one of the best in San Francisco taking in an entire block in the Mission section at Harrison and Twenty-first streets. The company will have sufficient spur track frontage to enable it to handle a trainload of machines at one time. It is understood that the investment represents a sum in excess of $125,000.

Convention of Lozier Dealers

DETROIT, MICH., July 15—Branch house managers and dealers of the Lozier Motor Company will assemble here next week for their second annual convention to be held July 17, 18 and 19. Lozier representatives in practically all the important cities and towns have been heard from and an unusually large attendance is expected. Since the 1911 convention the Lozier sales organization has increased rapidly and a big delegation of new dealers from all parts of the country will make their first inspection of the plant.

Plans for the coming year will be discussed at the conference and it is said that several announcements of more than usual interest to Lozier dealers will be made during the week.

Many of the dealers will probably remain over for a week to witness the ceremonies of Cadillaqua, Detroit's big celebration.

Foreign Makers Put Out Cheap Car

WASHINGTON, D. C., July 15—Consul Albert Halstead, Birmingham, England, says: "The success of the low-priced American automobiles in England has received the most careful attention of English manufacturers, with the result that one firm is now ready to put on the market an 800-pound car with wire wheels and gear drive that is expected to do about 40 miles an hour and to go a little over 30 miles per gallon of gasoline; the car complete is to sell for $650. One of the foremost French manufacturers is also prepared to put a car on the market to sell for the same price."

Slick Swindler at Work in West

ST. LOUIS, MO., July 13—A swindler who styles himself "Jay Deveroe" and combines a fine knowledge of motor cars with the names of prominent men in the trade, has attempted to obtain sundry sums from sales organizations in St. Louis.

Introducing himself as a "road service man" from one of the New England factories, he appeared at a St. Louis automobile salesroom recently and inquired for the factory sales manager, stating that the latter had left him in Indianapolis and instructed him to meet him in St. Louis.

"Deveroe" assumed that his knowledge of the sales manager's movements would forestall any demand for credentials. He became a zealous mechanic and for 3 days put in his time industriously. He appeared to be worried over the non-appearance of the sales manager, however, and produced what purported to be a telegram from him, stating that he has been delayed and would not reach St. Louis until the following Thursday, but instructing "Deveroe" to remain in St. Louis until he arrived. Claiming he had not received his expense check, he induced the bookkeeper to cash a personal check for $35. He also desired to send some money home, and in view of the fact that he had "about $150 coming to him for salary and expenses, which the sales manager would O. K.," he presented a check—drawn upon a trust company in the city where the factory is located—for $50. Telegraphic communication, however, brought back word that the checks were fradulent, but before this information reached St. Louis the "road service man" had disappeared.

New Line-Up for Cole Organization

INDIANAPOLIS, IND., July 15—With the absorbing of the Henderson Motor Sales Company by the Cole Motor Car Company, Charles P. Henderson, who was the head of the sales company, becomes the general sales manager of the Cole Motor Car Company. H. C. Lathrop, who was secretary and treasurer of the sales company, takes charge of the local branch of the Cole Motor Car Company with a large allotment of territory. Incidentally he has materially increased his holdings in the Cole Motor Car Company.

The organization which surrounded Mr. Henderson as head of the sales company goes bodily with the Cole Motor Car Company. Some advancements have been made. Ed. Harris, who was in charge of the promotion department, moves to the position of assistant sales manager; while Jay D. Riker, a new man coming from the Parry Buggy factory, takes the promotion department. John A. Murphy, cashier of the sales company, becomes assistant secretary of the Cole Motor Car Company. E. E. Rogers remains in his same post. Homer McKee holds down the job of advertising director; while H. C. Bradfield takes the road as traveling newspaper consultant.

Motorists Object to Gasoline Boost

PHILADELPHIA, July 11—Announcement by the Standard Oil Company of New Jersey today of an increase in the wholesale price of gasoline from 14 1-2 to 15 1-2 cents a gallon was immediately followed by a vigorous protest upon the part of dealers along Automobile Row. Notwithstanding the reasons advanced to support the contention of a necessity for the increase, local automobile dealers are a unit in declaring that the corporation, taking advantage of the large number of machines in use and realizing the indispensability of gasoline in their operation, is making the automobilist the "goat." As the individual owner is the one on whom the burden of the added cost will bear heaviest, dealers are apprehensive lest the discouraging prospect of still further advances which are claimed to be bound to occur will have the effect of decreasing the number of future sales.

Studebaker Bids for Canadian Trade

WALKERVILLE, ONT., July 13—An interesting development of the automobile situation in the Dominion is the formal entrance of the Studebaker Corporation as an active contender for the Canadian trade. The Studebaker interests are now in control of the Walkerville, Ont., plant, formerly known as the E-M-F Company of Canada, and are opening up an aggressive movement directed not only at the trade of the Dominion but also toward caring for the immense foreign automobile business which has been up to the present handled largely from the Detroit plant of the concern.

The Canadian business has been entirely reorganized and is now known to the world as the Studebaker Corporation of Canada, Ltd. A noteworthy feature in this connection is, however, the fact that in the reorganization the Canadian interests identified with the business from the beginning retain their holdings. A large part of the Dominion-owned stock is in the hands of the Walker family of Walkerville.

Willys to Take Over Garford August 1

TOLEDO, O., July 13—President John N. Willys, of the Willys-Overland Company, since his purchase of the Garford Company at Elyria, O., recently, will have complete charge of the Garford plant, though only in the capacity of general manager, until August 1, after which a reorganization will take place, when Mr. Garford and his officers will retire, giving way to President Willys and a new set of officials. The capital of the Garford company is $2,000,000, of which $1,500,000 is common, this latter amount representing Mr. Willys' purchase. The old selling arrangement between the Willys-Garford Sales Company and the Garford company does not terminate until the first of August, hence the reorganization date being set at that time. With the purchase of the Garford and the recent purchase of the Gramm company at Lima, O., the Overland dealers will have a complete line of pleasure cars and trucks to suit all tastes and purses. The Garford plant covers 23 acres and is unusually well equipped, but in the past things have combined to prevent the most being made of it facilities.

Boston to Have Two Shows Again

BOSTON, MASS., July 12—Boston will again have two shows in 1913. The pleasure car section under the auspices of the Boston Automobile Dealers' Association, Inc., will be held as usual in Mechanics' Building, March 8 to 15, inclusive, and the truck show held by the Boston Commercial Motor Vehicle Association, Inc., from March 19 to 26, inclusive.

The first exclusive truck show held last March was a great surprise to all—not only from the volume of business transacted but the general interest and attendance. Practically all the space was subscribed for, and a comparison with the other big shows was all in favor of Boston. From present indications and the applications for space the coming show will eclipse that of last year.

The pleasure car section will as usual prove the great magnet for entire New England—not only will every make of car be shown but elaborate preparations are under way for the usual unique decorative features.

Harking Back a Decade

FROM *The Automobile and Motor Review,* July 12, 1902:

Automobiles for carrying the Russian mails across the Caucasus are to supplant the present system of transporting it by relays of post horses with changes every 10 miles.

A glance at the interior of the tool-box will often give the observant critic a considerable insight into the character of the owner. The too-familiar cupboard, in which spanners, oil-cans, wire, loose nuts, and—too often—inner tubes as well, wallow in a marsh of split oil, grease and resin, sometimes has a variant in a clean and neatly kept receptacle, in which the orthodox set of tools reposes in place.

The Saxon Ministry has given its permission for the introduction of motor cabs in the more populous towns of Saxony, inasmuch as this new mode of locomotion will retain all the features of cab service as compared to other motor vehicles.

It is, of course, easily within the limits of national financiering and engineering to start at New York and build a model road west for 3,000 miles, but there is little likelihood of the road ever being completed in this manner. If the idea is ever realized, it will be an essential part, if not the culmination, of a general system of road improvement in which all the states will participate.—Editorial.

E. G. Walton, of Minneapolis, Minn., is the first to adopt the motor vehicle for showing real estate to prospective customers.

The F. B. Stearns Company, Cleveland, O., is planning another addition to its factory which is expected to more than double the capacity of the plant. Trouble in securing material has held the company back considerably of late, but it has managed to ship two or three machines each week.

It is now only a matter of weeks before the Winton Motor Carriage Company, Cleveland, O., will move from its birthplace in the old Brush plant to the fine group of buildings which looms up to the view of everyone entering the city from the west along the lake shore.

Nothing has been heard of late of the rotary motor which was in course of construction by Lieutenant Gaysdon, late of the United States Navy. A really practical rotary motor would upset present automobile practice to a terrible degree, but if quite reliable would undoubtedly advance the automobile movement by leaps and bounds in this country, where the uninitiated still talk of the noise, smell and vibration.

The 50-mile endurance run of the Automobile Club of Bridgeport, Conn., was a great success, with the exception that the road and weather conditions were too good, and the operators had such difficulty in holding the speed of their machines down to the legal and club limit of 14 miles an hour in the open sections and 8 miles in the towns, that a number have been disqualified and others are almost sure to be before the official report is published.

Calendar of Coming Events

What the Months Ahead Have in Store for the Automobilist—Shows, Conventions, Race Meets, Etc.

Shows, Conventions, Etc.

July 10-20.........Winnipeg, Man., Canadian Industrial Exhibition.
July 22-27.........Detroit, Mich., Cadillaqua Week.
Aug. 5-7.........San Francisco, Cal., Pacific Highway Convention.
Sept. 17-20........Denver, Col., Convention International Association of Fire Engineers.
Sept. 23-Oct. 3....New York City, Rubber Show, Grand Central Palace.
Dec. 7-22.........Paris, France, Paris Automobile Show, Grand Palais.
Jan. 4-11, 1913....New York City, Thirteenth Annual Show, Madison Square Garden and Grand Central Palace, Automobile Board of Trade.
Jan. 4-11..........Cleveland, O., Annual Automobile Show.
Jan. 20-25.........Philadelphia, Pa., Annual Automobile Show.
Jan. 27-Feb. 1.....Detroit, Mich., Annual Automobile Show.
Feb. 1-8..........Chicago, Ill., Annual Automobile Show.
Feb. 10-15.........Minneapolis, Minn., Annual Automobile Show.
Feb. 17-22.........Kansas City, Kan., Annual Automobile Show.
Feb. 24-March 1.. St. Louis, Mo., Annual Automobile Show.
March 3-8.........Pittsburgh, Pa., Annual Automobile Show.
March 8-15........Boston, Mass., Annual Automobile Show.
March 17-22.......Buffalo, N. Y., Annual Automobile Show.
March 19-23.......Boston, Mass., Annual Truck Show.
March 24-29.......Indianapolis, Ind., Annual Automobile Show.

Race Meets, Runs, Hill Climbs, Etc.

July 21...........St. Louis, Mo., Track Meet.
July 22...........Dallas, Tex., Farm and Ranch Tour, Dallas Automobile Club.
Aug. 8-10.........Galveston, Tex., Beach Meet.
Aug. 30-31.........Elgin, Ill., Road Races, Chicago Automobile Club and Elgin Automobile Road Racing Association.
Sept. 17...........Milwaukee, Wis., Grand Prize Race.
Sept. 20...........Milwaukee, Wis., Wisconsin Challenge and Pabst Trophy Races.
Sept. 21...........Milwaukee, Wis., Vanderbilt Cup Race.
Sept. ....Chicago, Ill., Commercial Vehicle Reliability Run, Chicago Motor Club.
Sept. ....Washington, D. C., Reliability Run, Automobile Club of Washington.
Sept. ....St. Louis, Mo., Track Races, Universal Exposition Company.
Oct. 7-11..........Chicago, Ill., Reliability Run, Chicago Motor Club.
Oct. 12............Salem, N. H., Track Meet, Rockingham Park.
Nov. 6.............Shreveport, La., Track Meet, Shreveport Automobile Club.

Foreign

Sept 26-Oct. 6.....Bourges, France, Agricultural Motor Car Exposition.
Nov. 8-16.........London, England, Olympia Automobile Show.
Jan. 11-22.........Brussels, Belgium, Annual Belgian Automobile Show. Centenary Palace.

The Automobile is a consolidation of The Automobile (monthly) and the Motor Review (weekly), May, 1902, Dealer and Repairman (monthly), October, 1903 and the Automobile Magazine (monthly), July, 1907.

Starter Problem Unsettled

WITH the present pronounced trend to electric lighting, self-starting and more adequate motor lubrication there is a corresponding loss of simplicity in many motors and an added complexity of piping, wiring and lack of accessibility in parts which is regrettable, and which proves conclusively that with many engineers the self-starting arrangement is not a dynamic part of the design but merely an added accessory, an accessory not taken into consideration when the general plan of the motor was made, but one adopted at a time when the engineering corps decided on its adequacy.

The lack of systematic arrangement and almost entire absence of symmetry in motor appurtenance layout speaks plainly of the present unsettled state of the self-starting art and naturally of the lighting art, in that they go together with not a few systems. This does not mean that the maker of the self-starting or lighting equipment has not mastered the art up to its present stage, but rather that the car engineer is lagging a little, has not kept quite up with the pace and therefore is surrounded with an atmosphere of uncertainty and complexity. In many cases he is hesitating between two and sometimes three opinions. In not a few cases he is uncertain as to the merits of the different outfits on the market, not having given them the drastic test; and in not a few cases, particularly in the field of higher car prices, he did not take up the consideration of the various systems as energetically as the times demanded and when it finally came to the deciding moment he was not sufficiently informed on all points to make a definite and clear-cut decision.

One year ago saw the avalanche to self-starters and electric lighting precipitated, just at a time when not a few car makers were ready to make their 1912 announcements. These were delayed a matter of weeks and, in some cases, months until a starter was selected and ways and means devised for installation. It was but natural to expect that the present season would have developed a stage of greater preparedness, but in many cases it has not. The engineering department in more than one factory has experimented with a certain make of lighting or starting apparatus over a period of many months, only to develop minor defects after long use—defects of such moment, however, as not to warrant the installation of such a system without some form of alternative to fall back upon in an emergency. Because of this the present season has aready witnessed makers announcing one form of starting equipment, and scarcely a month after such announcement adopting a new policy and deciding to install an entirely different type. With such uncertainty it is impossible to expect other than a mussed-up motor condition, which is seen more this season than for the last 3 or 4 years.

But the difficulty of the present situation is not all confined to the lack of clean-cut appearance, but rather to the uncertainty of the direction of movement in present changes. In the starter field, one maker talks the compressed-air system; at the next factory it has been set aside and only the electric system credited with the mark of approval; at a third factory both of these have been discarded and the acetylene system installed; a fourth sets its mark of approval on the mechanical type at the expense of all others. The net result is that scarcely one of the engineers has given that depth and breadth of research into the situation which it demands. Many of the engineers acknowledge this by the alternatives and substitutes they have installed. There are several motor plants for next season installed with not fewer than three different systems of devices to facilitate starting. Thus you will find a complete self-starter system of air, acetylene, electricity or other form this is augmented by a priming system connected with the gasoline or acetylene line; and added to this is a compression release outfit in connection with the exhaust camshaft. Other designers have installed both the acetylene and electric systems, one to help the other out and either to serve alone if the exigency arises.

Some years ago the duplication of parts was a feature of motor design that came in for general criticism, even the entire double system of ignition and especially the installation of two magnetos drawing the biting remarks of the critics. It was expected that the memory of those days would suffice for all time, but the periodic stampede provoked in the self-starter and electric lighting field has resulted in a return of such conditions. The return is not a credit in every case; the installation of a last-minute selection is apparent the moment the hood is lifted, and it is to be hoped that the experimental departments will work overtime and that soon the self-starting and electric lighting systems will be integral parts of the motor design and not excrescences as many of them appear today. As soon as this comes the public will have renewed confidence, the makers will have cheaper production and the results will be more creditable.

Ocean-to-Ocean Highway

Los Angeles Transcontinental Road Boosters Arrive in New York—Good Work Accomplished

WILMINGTON, DEL., July 15—On the last leg of the Old Trail Ocean-to-Ocean National Highway project—the object of which is to have a good road constructed across the United States, from the Atlantic Ocean to the Pacific—the campaign committee of the national association which is promoting the project left Wilmington this morning, having spent the night at the Hotel Wilmington, with the expectation of arriving at its destination, the Waldorf-Astoria hotel, New York, this afternoon at 5 o'clock. On leaving Wilmington it was proposed to go to New York by way of Sea Girt, N. J., with the hope of having a conference with Governor Woodrow Wilson, of New Jersey, the Democratic nominee for President of the United States, relative to enlisting his cooperation in the project. The party spent Friday and Saturday in Washington, where they conferred with President Taft and Speaker Champ Clark of the House of Representatives.

The purpose is to secure national legislation whereby the Federal government will bear half the expense of an improved highway across the continent, the states through which it passes to bear the other half of the cost, the expectation being that if Congress agrees to do its part the states will fall in line. In the campaign which ends today, so far as this particular movement is concerned, the party has organized the movement in fifteen states and has secured the signatures of 276,314 persons to a petition advocating the legislation, which will be presented to Congress next December.

Each of the signers is contributing $1 to the cause, the fund thus raised to be used in defraying the expenses of delegations to take the matter up personally with Congress, which is expected to be necessary to have the matter fully understood. The expenses of the campaign which ends today are being borne by the Los Angeles *Times*. The party which left here today comprised Col. Del M. Potter, of Clifton, Ariz., national organizer of the association; Bert C. Smith, a member of the news staff of the Los Angeles *Times*, and John F. Zak, of Los Angeles. The party left Los Angeles May 15, 1912, and since that time have organized the movement in the following states: California, Arizona, New Mexico, Colorado, Kansas, Missouri, Illinois, Indiana, Ohio, West Virginia, Maryland, Delaware, Pennsylvania, New Jersey and the District of Columbia.

When the pathfinder car arrived at Brighton Beach on Tuesday, July 16, a large crowd gathered to greet it. A vessel containing water which had been taken from the Pacific Ocean was emptied into the Atlantic amid the cheers of the throng.

Jericho Turnpike Open for Travel

After having been closed for nearly two years at points east of Woodbury, the Jericho turnpike, which is the main highway of the north side of Long Island, was opened last Friday. The state, at a cost of more than $10,000 a mile, has transformed this famous old country road into an ideal motorway.

The new section is 14 miles long, extending from the Nassau County line to the bridge over the Nissequogue River at Smithtown. Eleven miles are of concrete foundation with tar and gravel coating and the last 3 miles are of asphalt-macadam.

The turnpike is reached from New York by way of the Hoffman boulevard and Hillside avenue. It runs from the village of Queens through Floral Park, East Williston, Jericho, Woodbury and Commack to Smithtown. Beyond Smithtown the country roads are in fair condition, enabling the tourist to reach St. James, Stony Brook, Port Jefferson and other towns.

Jeffreys Talks on Roads

At Banquet Tendered Him in Boston Road Congress Secretary Comments on English and American Practice

BOSTON, July 13—W. Rees Jeffreys, of London, Eng., honorary secretary the Permanent International Association of Road Congresses, is in Boston as the guest of Col. William D. Sohier, chairman of the Massachusetts Highway Commission, and President Lewis R. Speare, of the Massachusetts State A. A.

He is the honorable secretary of the Third International Road Congress to be held in London, July, 1913, when highways and roads will be discussed by the most prominent men from all over the world. Mr. Jeffreys was a guest of honor at a dinner tendered him at the Union Club, Thursday night, by Col. W. D. Sohier, which was attended by Governor Foss.

In discussing his visit to this country Mr. Jeffreys said: "At Washington I appeared before a joint committee of the Senate and House of Representatives and outlined the importance of the road improvement movement throughout the world and I believe that this country will become a member of the congress.

"There is much in the English methods and practices that would prove useful to American engineers, for they would have an opportunity to learn from our mistakes and experiences and not repeat these mistakes over here. One thing in which the English experience would be most helpful is our practice in England of continuous maintenance.

"From the moment it is made a road requires attention. By our system a length of road of certain mileage is put under what is termed a lengthman. His duty is to attend to the small repairs, to patch a hole as soon as it appears, keep the water course clear and trim the sides of the road. As soon as the surface shows signs of wear along comes the steam-roller gang and a new top coat is placed in the highway. As a result of this the main structure is never cut into by heavy traffic. The roads in the United States that I have seen are well made, but they are not maintained properly. The result is that the sub-crust or foundation is gradually being destroyed and the capital expended is largely wasted.

"I believe that the United States through the Federal Government and the State authorities can well afford to concentrate on continuous lengths of road between various centers of population. For instance you have no good road from New York to Philadelphia; no good road from Philadelphia to Washington; from Washington to Pittsburg and from Pittsburg to Chicago. These roads when once constructed should be properly maintained, of course.

"There are three methods by which the highways are kept dustless. One is the application of tar every year, a second to surface them with tar macadam, and a third to put down a surface and grout it in with pitch and asphalt. These various methods would be interesting to American road engineers.

Automobile Bus Railway Feeder

SOUTH BEND, IND., July 13—Direct communication between South Bend and Buchanan was made possible when arrangements were completed with the Southern Michigan Railway to connect with an automobile service at Niles, Mich. Direct connection will be made with every other train in both directions. Through tickets will be sold to all points on the Northern Indiana and Southern Michigan systems. The deal was made with E. B. Clark, president of the Celfor Tool Company, of Buchanan, who contracted for a 15-passenger automobile bus, which is to be delivered within a month, and the service will be established immediately. A fare of 25 cents a trip will be charged between Niles and Buchanan.

Cole representatives in New York City and automobile writers of metropolitan dailies after a luncheon to President Cole

GATHERING of New York Cole Men—Following the informal luncheon of the New York City representatives of the Cole car and the automobile writers of the various metropolitan newspapers, during President J. J. Cole's Eastern trip, a part of the gathering were photographed, the group being shown in the above illustration.

Ford Sails for Europe—Henry Ford and family left Detroit, Mich., recently for a pleasure trip to Europe.

Club for Moundsville—The Moundsville, W. Va., Automobile Association has been organized with T. S. Riggs president.

Bus Line Is a Success—The Troy-Canton-Towanda, N. Y., motor bus passenger and freight line opened recently, proving a great success.

Everitt Opens in Columbus—The Everitt Auto Sales Company, recently incorporated in Columbus, O., for $30,000, has opened a place of business at 307-309 Mt. Vernon avenue, Columbus.

McBride Wins Promotion—D. K. McBride has been promoted from office manager of the Universal Motor Truck Company, Detroit, Mich., to the position of factory manager of the company.

Langhorn Leaves Packard—J. T. Langhorn has resigned as manager of the truck department of the Packard Motor Car Company, Detroit, Mich. Up to the present time he has made no plans for the future.

Bus Line Opened—An automobile passenger service has been opened between Gang Mills and Painted Post, N. Y., a Reo five-passenger machine being used. Later the service will be extended to Lake Lehcka.

Winter Now with Universal—H. L. Winter, formerly sales manager of the Federal Motor Truck Company, has taken the position of general sales manager with the Universal Motor Truck Company, Detroit, Mich.

Wilson Goes to Des Moines—Orrin S. Wilson, formerly manager of the Studebaker's Rocky Mountain branch at Denver, Col., has taken charge of the Iowa factory branch of the Studebaker Corporation in Des Moines.

Warehouse in San Antonio—Carl Harris, South Texas representative of the Studebaker corporation, is establishing a large warehouse in San Antonio, Tex., for the purpose of making that city the distributing center for South Texas.

Michigan's Show Promising—All the available space for the Michigan state fair automobile show has been taken, forty-one automobile firms having engaged booths. Electric, gasoline and commercial vehicle manufacturers are represented.

After the Cutout—An ordinance is pending in the City Council of Columbus, O., to stop all of the muffler noises on automobiles and motorcycles and it is believed the measure will become a law. The ordinance provides for fines from $10 to $50 for its violation.

Has Two Service Stations—The Imperial Motor Car Company, Cincinnati, O., representatives for Cole and Stearns cars, have moved into a new service building and salesroom at 1609 Madison road. They will also retain their old location at Peebles corners.

Lane a Railroad Director—M. H. Lane has been elected to membership in the directorate of the Grand Trunk Railroad to succeed E. H. Fitzhugh, who resigned to take the presidency of the Central Vermont Railroad. Mr. Lane is president of the Michigan Buggy Company, Kalamazoo, Mich., builder of the Michigan car.

Specializing on Supplies—The Jones Auto Company, Oakland, Cal., has given up the selling of automobiles, as its accessory business has increased to such an extent that it requires the company's entire attention. The two large stores of the company have been converted into one in order to centralize the business.

Stutz Agent Moves—The Stutz Motor Car Company, Boston, Mass., has moved into its new salesrooms, 895 Boylston street.

Discontinue Their Agency—J. C. and E. A. Kimmel, Columbus, O., who have been central Ohio distributors for the Speedwell, have discontinued business.

Bids Wanted in Columbus—The Columbus, O., Board of Health will receive bids July 25 for two 2-passenger, 4-cylinder, 20-horsepower automobiles for use in the health department.

Big Parade at Hornell—More than one hundred gorgeously decorated automobiles were in line in the parade held recently in Hornell, N. Y., in connection with the Old Home Week celebration.

Smith Is Sales Manager—Arthur T. Smith, formerly of the Packard Motor Car Company, has been appointed sales manager of the A. Elliott Ranney Company, New York City, distributors of the Hudson.

Evans in Charge of Trucks—H. W. Evans, who has been connected with the San Francisco branch of the Locomobile Company for the last 2 years, has been put in charge of the truck business of the company on the Pacific Coast.

Forestville Climb Postponed—Inability of the committee in charge of the third annual hill climb to secure sufficient entries for the various events was the cause for postponing the Forestville, N. Y., annual hill climb until next July.

Three Cars for Buffalo—The councilmanic board of Buffalo, N. Y., has granted permission to the public works department to purchase three automobiles, each to be uniform in color and the name of the department to be imprinted on each machine.

Formed to Handle Lincoln—The Baldwin Smith Motor Truck Company, Wichita, Kan., has been organized for the purpose of handling commercial motor trucks in Wichita and vicinity. They have become distributing agents for the Lincoln light delivery wagons.

For Automobile Regulation—The advisory commission to Mayor Shank has recommended that there be introduced in the Indianapolis, Ind., city council an ordinance forbidding motor cars to pass a street car while the latter is receiving or discharging passengers.

Line Between Elmira and Troy—A motor truck service for the shipment of freight and express consignments is soon to be conducted between Elmira and Troy, N. Y. The trucks will make daily trips between these points, receiving consignments along the route.

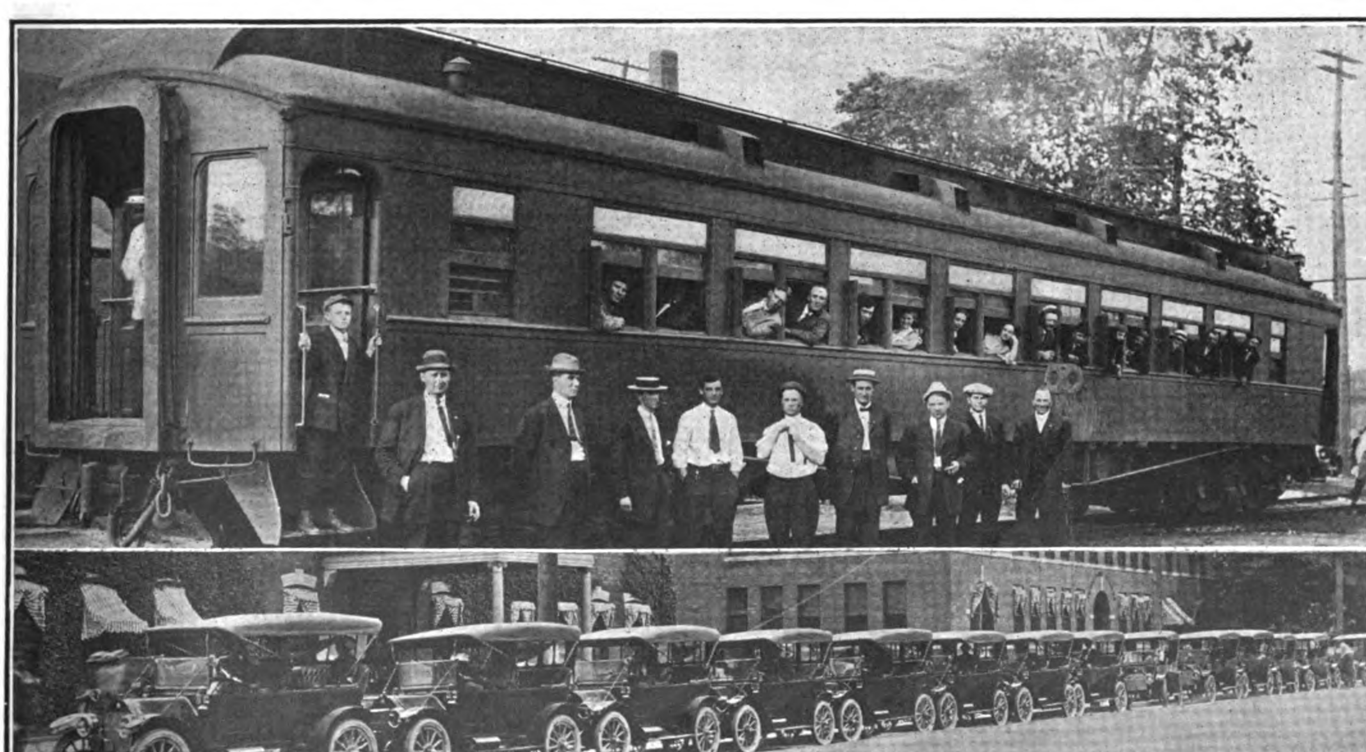
Radford Now Factory Manager—W. H. Radford has been promoted to the position of factory manager of the Warren Motor Car Company, Detroit, Mich. His former position as designing engineer and chief of the engineering department has been taken by W. H. Knowles.

Enlarge in Winnipeg—In order to meet the demands of business Joseph Maw & Company, Winnipeg, Man., are extending their premises. The firm has leased the ground floor of the adjoining Monarch Life Assurance Company building, which they intend using for exhibition purposes.

Orphans Entertained at Hamilton—Orphans' Day, which was held in Hamilton, Ont., recently, proved a great success. About thirty-five automobile owners donated their machines for the use of the orphans, who were driven to Grimsby Beach, where races featured the afternoon's entertainment.

Ground Broken for Building—Work has already started on the new building for the United States Tire Company at the junction of Beacon street and Commonwealth avenue, Boston, Mass., and the foundation will be finished shortly. It is expected that the new structure will be ready for occupancy by January 1.

Reo Tourists Arrested—Thirty enthusiastic automobilists from Fort Dodge, Ia., including five ladies, recently left the Reo factory at Lansing, Mich., in their newly-purchased Reo cars for Fort Dodge—a 600-mile trip. They displayed Iowa license tags on their cars and the Lansing police, misunderstanding the provisions of the state law regarding non-residents, arrested the entire party. The matter was straightened out and the tour was continued.



Upper picture shows the specially chartered Pullman in which thirty enthusiastic automobilists traveled from Fort Dodge, Ia., to the Reo factory at Lansing, Mich. Lower picture shows the fifteen new Reos in which the party returned to Fort Dodge

Special Cole of the Princess Victoria, showing coupé body small enough for the little lady

Culp Financial Manager—George P. Culp has been appointed financial manager of the automobile business of A. M. Zimbrich, Rochester, N. Y.

May Use Automobiles—The International Railway Company of Buffalo, N. Y., is considering the advisability of installing automobile wagons in the emergency department.

Reed Wins Promotion—F. L. Reed has been promoted to the general managership of the Schacht Motor Car Company of Canada, with general office and factory in Hamilton, Ont.

Branch in Nashville—The Oakland Motor Company is installing a factory branch at Nashville, Tenn., in charge of M. D. Stone. A repair shop of considerable size will be equipped.

Stewart Is Manager—J. O. Stewart is the newly appointed manager of the Spokane, Wash., branch of the Diamond Rubber Company. Mr. Stewart succeeds W. J. Voit, who removed to Los Angeles.

Back to San Francisco—In the recent readjustment of the Pioneer Automobile Company, of San Francisco, Cal., A. C. Wheelock, the former Fresno manager, returns to San Francisco as assistant manager of the main office.

Monson General Manager—M. J. Monson has been appointed general manager of the Wisconsin and upper peninsular branch of the Buick Motor Company, with headquarters at the district branch house in Milwaukee.

Essenkay in Boston—The Essenkay Company, Chicago, Ill., has leased the quarters in the Motor Mart, Boston, Mass., formerly used by the Alvan T. Fuller Company, agent for the Packard, and will be ready to do business soon.

Sell Out Interests—Christopher F. Whitney and Charles H. Barney have sold out their interest in the Whitney-Barney Company, Boston, Mass., to Frank B. Wilcox. The latter and Fred P. Lucas will probably carry on the business.

Philadelphia Sells Horses—Director Cooke, of the Philadelphia department of public works, has ordered the sale on Friday, July 19, of the horses and carriages heretofore used by the local Highway Bureau inspectors. Automobiles will be used in their stead.

New Ordinance in Dayton—A new police traffic ordinance has gone into effect at Dayton, O., the chief provisions of which relate to the keeping on the right side of the street, backing up automobiles or other agents of transportation to the curb and paying strict attention to the orders of the police on the subject of traffic.

Quits Brokerage for Motor Business—M. E. A. Stoddard, one of the largest stockholders of the Stoddard Motor Car Company, Springfield, Mass., has resigned as manager of the Springfield branch of T. G. Coombe & Company, members of the New York stock exchange, to give his entire time to the management of the motor agency.

Distributes Copies of State Law—In order to bring about a better understanding of the laws of the road and to minimize the danger from accidents the Automobile Club of Vermont has had printed a large number of small fliers in which that section of the state law governing the mode of travel on the highways is covered. These are being distributed to motorists and owners of horse-drawn vehicles.

Big Rambler Convention—The annual convention and school of instruction for Rambler representatives was held at the factory of the Thomas B. Jeffery Company, Kenosha, Wis., July 9, 10 and 11. More than 100 branch managers, sales managers and agents were present to inspect the next issue of Rambler cars and attend the experience meetings.

Sheboygan Elects Officers—The Sheboygan Machine Company, Sheyboygan, Wis., organized several months ago by former associates in the Falls Machine Company, of Sheboygan Falls, Wis., has elected the following officers: President, Frederick Karste, Jr.; vice-president, Albert Teffen, Jr.; secretary, Charles Kummers; treasurer, Lester Nelson. The company is capitalized at $10,000 and is engaged in the manufacture of gasoline motors and other machinery.

State Officials at Bretton Woods—Motorists from other states who go touring through the White Mountains of New Hampshire this summer, and who wish to stay more than the allotted 10 days in the state, can get a 3-month registration now at reduced rates. Those who tour through from the North and visit Bretton Woods will not need to go to Concord to the office of the secretary of state, for that official has appointed a deputy with headquarters at the Mt. Washington Hotel to issue registrations.

Princess Victoria Coupé—The Princess Victoria, called the Miniature Melba of the footlights, is a stage curiosity. In order to make her appeal more strongly to the public her manager uses a white-enameled Cole and a giant liveried footman as features in traveling about the country. The car is a regular stock machine except that a coupé body is mounted in the rear of the roadster seats, the gasoline tank having been placed under the body.

Automobile Incorporations

AUTOMOBILES AND PARTS

Brooklyn, N. Y.—Dunham Auto Company; capital, $15,000; to deal in automobiles. Incorporators: D. Dunham, L. Carmadella, C. L. Apfel.

Camden, N. J.—Auto Distributers Limited Company; capital, $200,000; to manufacture, buy and sell automobiles and other vehicles. Incorporators: Frank R. Hansell, J. C. Clow, John A. McPeak.

Chicago, Ill.—Dearborn Automobile Company; capital, $10,000; to manufacture automobiles and accessories. Incorporators: Sidney Oppenheim, Author Rosenthal, John C. Ahrensfeld.

Cleveland, O.—Clutch Company of Cleveland, capital, $200,000; to manufacture and sell friction clutches and lubricating devices. Incorporators: J. W. Thorman, O. W. Carpenter, H. F. Meyer, C. C. Clelland, B. W. Ten Eyck.

Columbus, O.—Ideal Motor Car Company; caiptal, $200,000; to manufacture automobiles.

Goshen, N. Y.—Coates Commercial Car Company; capital, $250,000; to manufacture freight automobiles. Incorporators: Robert Gibson, Jr.; L. Barton Case, Powell Crichton.

Grand Rapids, Mich.—Austin Automobile Company; capital, $500,000; to manufacture automobiles. Incorporators: James E. Austin, Walter S. Austin, George H. Davidson.

Muncie, Ind.—Miko Machinery & Supply Company; capital, $1,000; to deal in machinery and material for the manufacture of automobiles. Incorporators: Carl D. Fisher, J. M. Heron, O. B. Bannister.

Newark, N. J.—W. S. Motor Company; capital, $300,000; to manufacture automobiles. Incorporators: J. M. Woods, C. H. Tebbets, L. F. Fetser.

New York City.—Munsing Tractor Company; capital, $600,000; to manufacture and deal in automobiles. Incorporators: Basil Mager, Robert H. Allen, Herman C. Kluse.

New York City.—Stationery & Marine Motor & Supply Company; capital, $50,000; to manufacture motors and supplies. Incorporators: Thomas Lillis, Ralph A. Corely, Frederick W. Knipscher.

Portland, Me.—Universal Motor Truck Company; capital, $10,000; to manufacture and deal in automobiles. Incorporators: Clarence E. Eaton, T. L. Croteau, James E. Manter.

Rochester, N. Y.—Shafer-Decker Company; capital, $50,000; to manufacture and deal in automobiles. Incorporators: C. P. Hugo Schoellkopf, Charles B. Shafer, Frederick J. Decker.

Syracuse, N. Y.—New York Motor Company, Incorporated; capital, $10,000; to manufacture motors. Incorporators: Ernest W. Lawton, Theodore Young, Charles S. Lawton.

Syracuse Orphans Ride—The Automobile Club of Syracuse gave the inmates of the Onondaga Orphans' Home their annual ride recently, fifty automobiles being filled to capacity.

Fosdick Resigns from Stevens-Duryea—Harry Fosdick, sales manager of the Stevens-Duryea Company, Chicopee Falls, Mass., has resigned from his position with the company.

New Seattle Hudson Agent—James C. Murray, formerly representative of the Hudson company in Seattle, Wash., will be succeeded by G. L. Rodd, who will head the Pacific Motor Car Company.

Peoria Cadillac Crew Parades—The first annual gathering and parade of Peoria, Ill., Cadillac owners was held in that city a few days ago. There were 160 cars in line, which paraded through the city.

Fire Protection Installed—A complete fire protection system has been installed in the Mitchell Garage, Racine, Wis., at a cost of $5,000. The garage is now regarded as a model from the safety standpoint.

Moves to Detroit—J. A. Thorsen, advertising manager of the Lion Motor Car Company, Adrian, Mich., has transferred the advertising headquarters of the company to Detroit, where he will be located hereafter.

Tuttle Quits Dayton Management—Harry Tuttle has announced that on August 1 he will sever his connection with the Dayton Motor Car Company, Dayton, O., for which he has acted as service manager for some time.

Automobile Street Car Service—The thriving town of Dayton, Ore., located 33 miles southwest of Portland, has recently established the first automobile street car service in the state of Oregon. M. G. Miller is the owner.

Promotion for Windholz—R. L. Windholz has been made the head of the recently established Detroit office of the Sloan & Chace Manufacturing Company, Newark, N. J., manufacturers of precision machinery and special tools for the automobile trade.

Visits Detroit Company.—A. Boulade, general manager of the French Societé du Carbureteur Zenith, recently visited the factory of the Zenith Carbureter Company, Detroit, Mich. The capital of this company has lately been increased from $10,000 to $50,000.

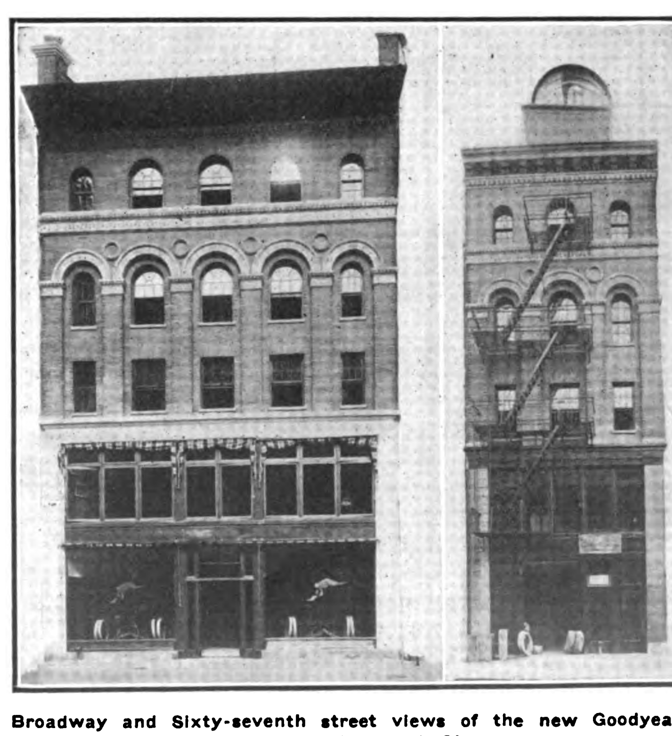
'Bus Company Reduces Fares—What is believed to be the lowest tariff of fares charged in the country by a motor 'bus company has just been placed in effect by the Rapid Motor-transit Company, Indianapolis Ind., which is now selling six tickets for 25 cents and twenty-five tickets for $1. This reduction has been made to meet the fares charged by the street railway company.

Kansas City Agencies Discontinued—There will be many changes in the managements of agencies and branches of Kansas City, Mo., in the near future. The Albertson-Boyd Motor Car Company, former agents for Marmon and Hudson products, have discontinued these lines and both manufacturers will institute factory branches. The Everitt and Franklin factories have also installed factory branches.

Columbus Seal Red and Blue—The Columbus Automobile Club, Columbus, O., has adopted a red and blue flag bearing the seal of the state of Ohio as a pennant, to be carried on all cars of the members. The purpose is to advertise the coming state centennial celebration. On the night of August 26, the members of the club will join in a big automobile parade which will be preliminary to the centennial celebration.

New Goodyear Building—The Goodyear Tire & Rubber Company of New York has moved into its new building at Broadway and Sixty-seventh street, New York City. The structure is an L, five stories and basement, with 20,000 square feet of floor space. The company has also purchased 2 acres of land in Long Island City and will erect thereon a six-story warehouse of 96,800 square feet of floor space. This warehouse will be ready for occupancy by January 1, 1913.

Wesco Now Wholesale—The Wesco Supply Company, St. Louis, Mo., manufacturers and jobbers of electrical supplies, have recently taken up the handling of automobile accessories at wholesale. They have warehouses in Fort Worth, Tex., and Birmingham, Ala., in addition to their large building at Seventh street and Clark avenue, St. Louis, Mo., and have twenty-five salesmen on the road. The automobile accessories department has been placed in charge of A. E. Rosenberg.



Broadway and Sixty-seventh street views of the new Goodyear building in New York City

Automobile Incorporations

Grand Rapids, Mich.—Simpson Automobile Supply Company; capital $35,000; to buy and sell automobiles, supplies and accessories. Incorporators: E. W. Simpson, E. R. Corbin, F. J. Goders.

GARAGES AND ACCESSORIES

Cincinnati, O.—Acme Motor Delivery Company; capital, $15,000; to haul and deliver goods by automobiles. Incorporators: William Ernst Minor, Fred L. Allen, Stuart B. Sutphin, David Washman, James Bradford Minor.

Cleveland, O.—Saunders Auto Supply Company; capital, $20,000; to manufacture and sell automobile lever locks and other accessories. Incorporators: C. J. Robinson, S. W. Sparks, J. A. Blakely, B. V. Selby, Ishen F. Allen.

Grand Rapids, Mich.—Grand Rapids Motor Realty Company; capital, $50,000; to conduct the affairs of the Grand Rapids Automobile Club. Incorporators: Charles A. Phelps, Alvah W. Brown, M. T. Van Den Bosch, Elmer Kinsey, G. A. Hendricks, O. H. L. Wernicke, R. E. Tietsert, Harold V. M. Tuthill, C. H. Walker.

New York City.—Circle Taxicab Company; capital, $2,800; to engage in the taxicab business. Incorporators: John Hefferon, Margaret T. Hefferon, John F. Kavanagh, Catherine J. Kavanagh.

New York City.—Resident Punctureless Tire Company; capital, $200,000; to manufacture a punctureless tire. Incorporators: Flossie M. McGrady, Seth H. Sheldon, LeRoy McGrady.

New York City.—Tanney Rubber Company; capital, $10,000; to manufacture rubber goods and tires. Incorporators: Harry Tannerbaum, Jacob Tannerbaum, Philip F. Tannerbaum.

New York City.—William C. Reynolds, Inc.; capital, $3,000; to deal in automobile supplies. Incorporators: Charles W. Reynolds, Rene Dequet, Otto Schiller.

Syracuse, N. Y.—Jefferson Garage Company; capital, $30,000; to conduct a garage and repair business. Incorporators: A. Metzen, C. J. Rochm, C. J. Blaumer.

CHANGES OF CAPITAL

Akron, O.—Akron Rubber Mold & Machine Company; capital increased from $10,000 to $30,000.

Augusta, Me.—Universal Motor Truck Company; capital increased from $10,000 to $500,000.

Bridgeport, Conn.—Locomobile Company of America; capital increased from $5,000,000 to $6,500,000.

Detroit, Mich.—Zenith Carbureter Company; capital increased from $10,000 to $30,000.

Mrs. E. A. Blaney, of Cincinnati, O., in her Ohio car

Cincinnati Has Woman Tourist—Mrs. E. A. Blaney, Cincinnati, O., has acquired a considerable reputation as a cross-country driver. The accompanying illustration shows Mrs. Blaney in her Ohio roadster.

New Frisco Oldsmobile Manager—George S. Morrow, formerly factory representative of the Oldsmobile Company, has been made retail sales manager of the San Francisco, Cal., branch.

Ford Western Agent Moves—The Alkire-Smith Auto Company, Utah, Western Wyoming and Southern Idaho agents for the Ford car, has moved to its new quarters at 67 West Fourth street, Salt Lake City.

Marmon Considers Another Branch—The Nordyke & Marmon Company, Indianapolis, Ind., is considering the establishment of a branch in Kansas City, Mo. Fred Clinton is looking for a suitable site for the factory.

Diamond Los Angeles Change—F. O. Nelson, manager of the Los Angeles branch of the Diamond Tire Company, will be succeeded in that position August 1 by W. J. Voit, now branch manager at Spokane, Wash.

St. Louis Buys Cars—The city of St. Louis, Mo., has bought fifteen Ford roadsters for use of the inspectors in the street and other departments. Touring cars for the heads of the several departments are also to be purchased, bids having been called for furnishing them. The city will also buy two 5-ton trucks, a 2-ton truck and a 1,500-pound motor wagon.

Motors Usurping Hand Cars' Place—The Toledo & Ohio Central has adopted gasoline motor cars for track work and inspection. Five modern type gasoline cars have been placed at the disposal of section men operating from Bellefontaine, O., and intervening points. Old-time hand-cars are disappearing from all the railroads.

Gets New Landlord—The property at 754 Main street, Buffalo, N. Y., which is occupied by the Pierce-Arrow Company's sales department and garage was sold this week by William H. Hotchkiss to Walter L. Schoellkopf for $250,000. The purchase was made solely as an investment and the Pierce-Arrow Company will remain in the building.

Klose Made Branch Manager—O. W. Klose has been made manager of the United Motor Minneapolis Company, Minneapolis, Minn., to succeed E. B. Stimson. Appointment was made by S. D. Porter of Kansas City, western supervisor. Mr. Klose has sold Maxwell cars for 8 years. He is the youngest branch manager with the company.

Foss-Hughes Buys in Providence—The Foss-Hughes Automobile Company, which has the agency for the Pierce-Arrow car for Providence, R. I., Philadelphia and other cities, has purchased 35,000 square feet of land at the corner of Wesleyan avenue and Plenty street, Providence, R. I., for the purpose of erecting a modern brick salesroom and service depot. Work on the new building will be started at once.

News of the Garages

Largest in State—The garage being built for W. A. Kirk New Haven will be the largest one in the state, a cording to the builders, the structure being four stories hi with 40,000 square feet, with a capacity for 250 cars. A ton elevator will be installed to carry the cars up and down.

New Garage at Groveland—H. L. MacDonald, who has t agency for the Kissell Kars at Groveland, Mass., has ju completed a large brick garage.

Sells McClure Garage—J. M. Connolly has sold the M Clure Garage, located at McClure, O., to John Harmon f $2,500.

Service Station for Everitt—A new garage and service s tion four stories high and about 90 by 50 ft. is being erect in Boston, Mass., for the local agency for the Everitt car.

To Build in Louisville—The Clark Motor Company, Lou ville, Ky., has acquired a 10-year lease on a site on Bro way, where the company proposes to erect a $15,000 buildi

To Build in Albany—John Croissant has completed pl for the construction of a large automobile garage at Washington avenue, Albany, N. Y. The building will three stories in height.

New Ford Service Station—The Ford Motor Company pects to occupy its new service garage in Winnipeg, M during the latter part of July and will set apart space for accommodation of the Minneapolis and St. Paul tourists ing their tour to Winnipeg.

Almost Ready in Winnipeg—The Tudhope Anderson C pany will soon take over its new garage in Winnipeg, M and will have a complete service plant for the benefit of T hope car owners. This is the same car as the Amer Everitt, but sold under the Tudhope name in Canada.

Addition to Paulding—The Paulding Auto Company, Paulding, O., is building an addition to its present establishment.

To Open in Riverton—C. A. Thuman is building a garage in Riverton, Ia., where he will engage in the automobile business.

New Garage in Omaha—Andrew Murphy & Son, Omaha, Neb., have started work on a new garage next to their present building.

Change in Punxsutawney—P. O. Freas has disposed of his garage in Punxsutawney, Pa., to T. M. Kurtz, who will continue the business.

To Conduct Garage—The West Allis Machinery & Auto Company has been formed in West Allis, Wis., to conduct a garage and machine shop.

Packard Building Garage—A one-story garage, 137 by 69 ft., is being constructed in Philadelphia for the Packard Motor Car Company. The building will cost $12,000.

Eureka Company Builds Addition—The Eureka Motor Car Company is preparing for the construction of an addition to their garage on Adams avenue, Scranton, Pa.

Bosworth Makes Extensive Addition—An extensive addition is being made to the automobile plant and garage of E. G. Bosworth & Company in Birmingham, Ala.

Building in Baltimore—The Colonial Motor Company, Baltimore, Md., is having a new garage built. It will be two stories high, of ornamental concrete and brick.

Another $12,000 Garage—Edward Cunningham is building a one-story garage at Twenty-second and Race streets, Philadelphia, Pa., for the Pennsylvania Galvanizing Company, to cost $12,000.

Garage for Plymouth—Torke Brothers are erecting a three-story building of fireproof construction, 50 by 120 feet, in Plymouth, Wis., to be used for garage and machine shop purposes. It will cost $30,000.

Completed in Shreveport—A new fireproof garage has been completed for the Orme Motor Car Company, Shreveport, La. The new building cost $8,000. The Orme company handles the Moon.

$12,000 Garage for New York—Otto Freyer will build a one-story brick garage, on the south side of 155th street, New York City. Plans filed by Architects Horunburger & Bardes place the cost at $12,000.

To Open in Buffalo—An automobile association known as the "Auveco," recently formed in Buffalo, N. Y., is completing arrangements for the opening of a commercial and pleasure vehicle garage and salesroom.

Adopt Garage Amendment—Following a hearing in the board room of the District Building recently the Commissioners adopted an amendment to the building regulations, providing for the colonization of public garages in Washington, D. C.

Franklin in Milwaukee Enlarging—The Franklin Automobile & Supply Company, Milwaukee, Wis., local dealers in Franklin automobiles, are enlarging their quarters to include a frontage from 321 to 327 Fourth street. Every modern facility is being provided to make this garage and salesroom one of the best equipped in the Middle West.

Celebrates National Victory—After Joe Dawson's National won the 500-mile race at the Indianapolis Speedway various agencies for that car celebrated the victory by decorating their showrooms. Among these was the Howard Auto Company, Portland, Ore., whose salesroom is shown in the accompanying illustration.

Largest Company in Northwest—By taking over the Conge Motor Company garage, St. Paul, Minn., the White Bear Automobile Company, A. J. Diamon, president, lays claim to being the largest automobile company in the Northwest. The company plans service garages in all parts of the city. It occupies one building in St. Paul, another at White Bear Lake and a third building is being erected, and a contract will be let soon for an electric station.

Bangor Garage Burned—The garage of the S. L. Crosby Company of Bangor, Me., was destroyed by fire recently and about 40 cars were either destroyed or badly damaged. The fire was caused by the ignition of a gasoline tank on a brazier and spread so quickly it was impossible to check it or remove the cars. Roger H. Swan, one of the employes, was badly burned about the face and body and two others were slightly burned before they managed to get out. The loss on the building was $15,000, but the loss on the cars could not be estimated.

National agent in Portland, Ore., celebrating victory

Motor Fire Apparatus

To Buy a Fire Truck—The Grand Island, Neb., city council is considering the purchase of an automobile for fire-fighting purposes. It is thought that a $6,000 car will be necessary for the requirements of the city.

Another for Peoria—The city of Peoria, Ill., will be the owner of five automobiles when the machine recently authorized by the city council for the fire department is purchased.

Columbus Council Approves—The city council has approved an ordinance for the establishment of a fire engine house in the hill-top section of Columbus, O., to be equipped with motor-driven fire apparatus.

West Chester Wants Apparatus—West Chester, Pa., is contemplating the holding of a special election to determine whether the town council shall be authorized to borrow $25,000 for the purpose of purchasing motor fire engines.

Portsmouth Adopts Fire Wagon—The Pope Hartford Motor Car Company delivered a motor fire wagon to the city officials at Portsmouth, N. H., recently, the vehicle being driven over the road from the factory to Hartford. It was put into service at once.

Rike Kumler Company Cars—The fleet of cars shown in the illustration comprises the delivery equipment and private cars of the Rike Kumler Company, Dayton, O. All are equipped with Aplco electric lighting systems. The delivery cars are Speedwells.

Beverly Trying Out Fire Wagons—The city officials of Beverly, Mass., have been testing out various makes of motor apparatus to be added to its fire equipment, and it is expected that a decision will be reached shortly and at least one will be added to the department.

Fire Wagon Meets Requirements—The Minneapolis, Minn., council committee has recommended for purchase a Nott Fire Engine Company gasoline pumping engine, contracted for in March at $6,500, providing the machine filled the efficiency requirements. Tests thus far have produced results above specifications.

Motorizing Houston Department—Fire Commissioner Colehause of Houston, Tex., has placed orders with the American-La France Fire Engine Company, for a 65-foot aerial truck, one motor water tower and a triple combination auto engine. The aim of the Houston fire officials is to motorize the entire department in that city.

Philadelphia in Difficulty—As the bids submitted to the Philadelphia department of public safety for motorized fire equipment exceeded the $35,000 available for that purpose, there is serious question as to whether the present horse-drawn equipment will be superseded in the near future, and the preliminary establishment of a "flying squadron" has been indefinitely postponed.

Cincinnati in the Market—Safety Director Cash of Cincinnati, O., will soon advertise for bids to furnsh the city fire department with automobiles as follows: One runabout for the fire alarm superintendent; one runabout for the mechanical superintendent, and one runabout for each of the two fire marshals. The runabouts should have 20 to 40 horsepower. The city will also buy two combination pumping engine and hose wagons of 70 horsepower each and four combination chemical engines and hose wagons of 50 horsepower each.

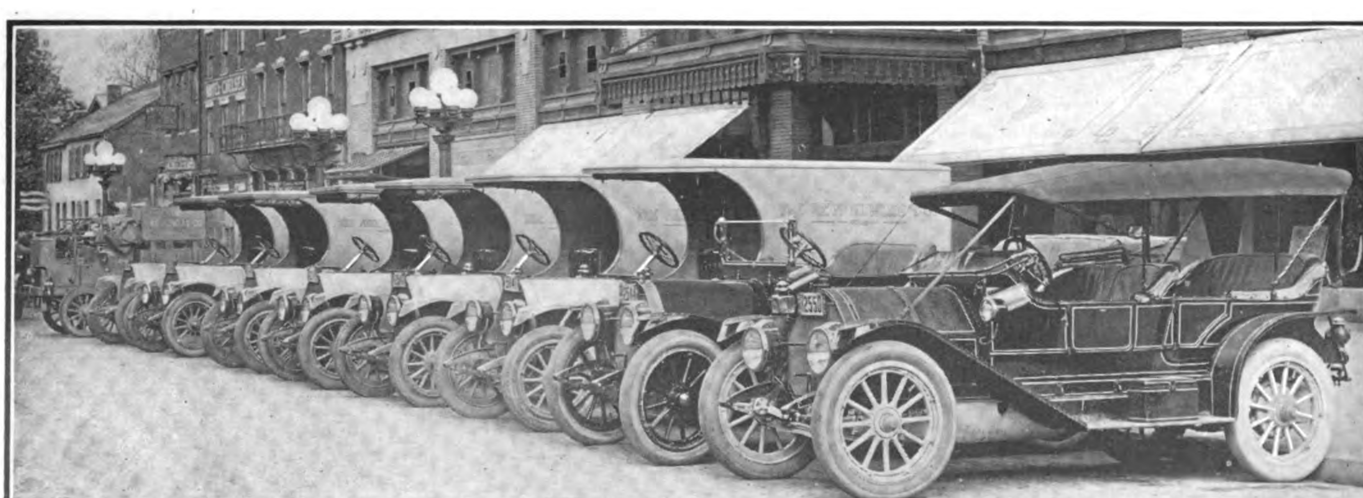
Penn Yan Buys Apparatus—The Ellsworth Hose Company of Penn Yan, N. Y., has placed an order with the Eureka Fire Hose Company, Syracuse, N. Y., for one 32-horsepower combination motor truck and chemical engine made by the Seagraves Manufacturing Company, Columbus, O. The apparatus weighs 3 tons, carries 1,000 feet of fire hose, 150 feet of chemical hose, one 40-gallon tank for chemicals, one 21-foot extension ladder, one 12-foot straight ladder, will travel 25 miles per hour and costs $2,400.

District Service to Be Motorized

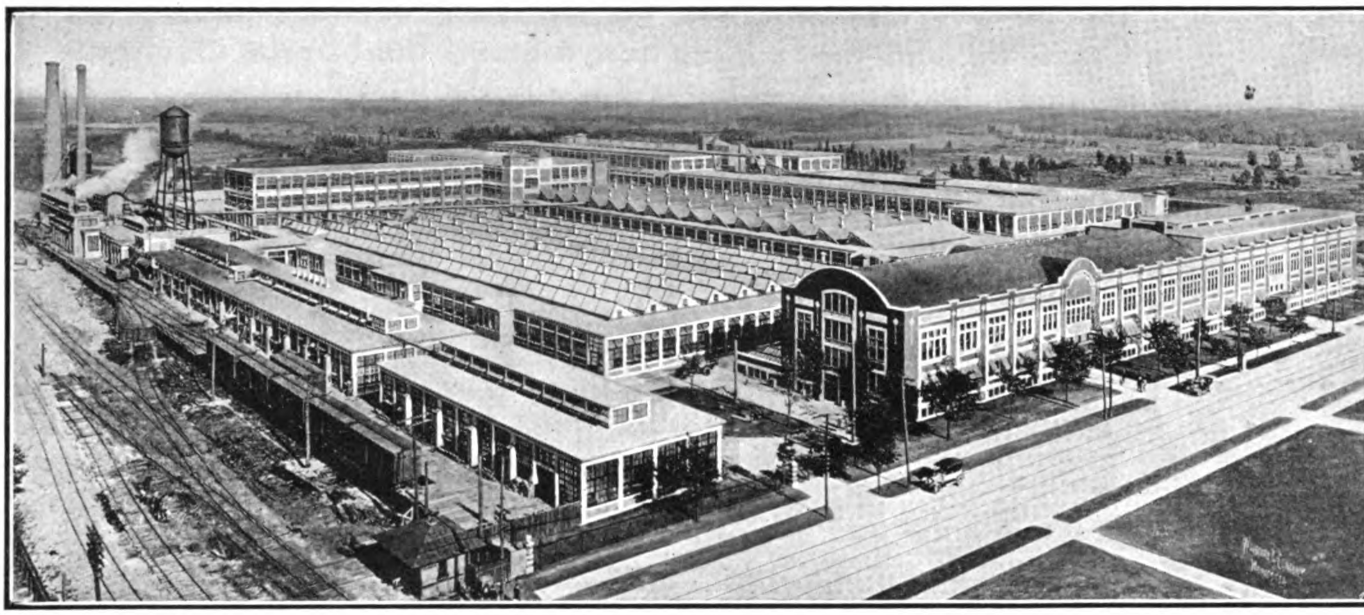
WASHINGTON, D. C., July 14—Motor cars are rapidly replacing horses in the municipal service of the District of Columbia. Included in the district appropriation bill just enacted by congress are appropriations for the purchase of motor vehicles for the use of the building inspector, superintendent of sewers, electrical engineer and superintendent of street cleaning. A number of other district officials are already provided with machines for their official duties.

Experience has demonstrated, according to district officials, that motor cars give a greater measure of service than the horse-drawn vehicles and are operated at less cost. The policy of the district commissioners is to gradually replace the horse-drawn fire apparatus with motor-propelled engines, hose wagons and trucks.

The District of Columbia at present is the owner of two pieces of motor-driven apparatus, a fire engine and a combination fire engine and hose wagon. Provision is made in the district appropriation bill for the purchase of another combination fire engine and hose wagon at a cost not to exceed $9,000. Bids for the purchase of this apparatus will be called for in the next few weeks.



Delivery and private cars used by the Rike Kumler Company, Dayton, O. All are equipped with Aplco electric lighting systems



Birdseye view of the handsome factory buildings of the Pierce-Arrow Motor Car Company, 1695 Elmwood avenue, Buffalo, N. Y.

IMPERIAL Enlarges Plant—The Imperial Automobile Company is now owner of the factory buildings in Jackson, Mich., where the Buick Motor Company has been manufacturing automobile trucks. The Buick will transfer its Jackson business to the main plant at Flint. The buildings in Jackson cover 7 acres and the company will enlarge its output from about 1,700 to upward of 5,000 vehicles.

R-C-H Uses Tents—The plant of the R-C-H Corporation at Detroit, Mich., being in need of more room for the production of 1913 cars, is using three large tents for the purpose.

Grant Factory Moved—The Grant Motor Car Company, manufacturer of the Grant Six, is now moving into its new factory at One Hundred and Fifty-second street and St. Clair avenue, Collingwood, O.

Lewis Company Growing—The Lewis Spring and Axle Company will enlarge its Jackson, Mich., plant and probably will build automobile trucks of 9 tons capacity. The company has been experimenting with cars of this type for some time and one of them has proved satisfactory.

Stewart Company Leases Plant—The newly-organized Stewart Motor Corporation, Buffalo, N. Y., capitalized at $250,000, has leased the factory of the Niagara Machine & Tool Works at Jefferson, Superior and Randall streets. The company will manufacture light-capacity freight automobiles.

Work Resumed at Fremont—Building operations which have been delayed for some little time at the Lauth-Juergens plant at Fremont, O., have been resumed since the arrival of the steel for the framework of the new addition. Sales-manager H. S. Diller announces that the building will be completed within the next 30 days.

Cole Factory Expands Again—President Cole of the Cole Motor Car Company, Indianapolis, Ind., has announced that arrangements have been made to construct another addition in the form of a wing to the Cole factory. The new wing will be adjacent to the one built a short time ago and will be erected at an approximate cost of $100,000.

To Build Light Trucks—The Ideal Motor Car Company, Columbus, O., has been incorporated with a capital of $20,000 by C. G. Amendt, J. C. Reichart, D. N. Postlewaite, T. J. Shaffer and E. Braugnier. The object of the company, which is composed mostly of Detroit capitalists, is to establish a plant for the manufacture of light delivery trucks.

To Manufacture in Rochester—With the discontinuance of the Jenkins Motor Car Company, Rochester, N. Y., in the manufacture of pleasure gasoline vehicles, the Cole Rochester representatives have taken over the entire plant of the Jenkins company in the eastern section of the city. They have acquired new capital and will manufacture and sell automobiles under the name of the Shafer-Decker Company.

Addition for Kinsey Plant—A five-story brick addition is being built to the Kinsey Manufacturing Company's plant, Toledo, O., and will be ready for occupancy in the early winter. The dimensions of the new building will be 125 by 100 feet. It is designed solely for manufacturing purposes and will necessitate the employment of 300 more men. The Kinsey is one of the Willys-Overland group of automobile concerns.

Goodyear Makes Big Addition—The Goodyear Tire & Rubber Company, Akron, O., has commenced work on another new building to be added to its present group. It will be 400 feet long, 80 feet wide and six stories high. The new building will be of brick and stone and will be fireproof. The same company has let contracts for two-story additions to two of its present large buildings. When completed the Goodyear company will have a plant containing 266,000 square feet of floor space. The enlarged factory will have a capacity of 8,000 tires a day and will give employment to 2,000 additional men.

Refreshment Basket for Touring; Tire Pump Driven by the Engine; Acetylene Lighting System Controlled from the Driver's Seat; Channel Steel Spring Bumper; Tire Holder for Attaching Extra Tires to the Back of a Car

Hawkeye Refrigerator Basket

JULY touring has charms which are easily marred by a lack of general comfort. The carrying of fresh and cool eatables and drinks greatly increases the pleasure of summer motoring, and to assist the automobilists in this direction, the Burlington Basket Company, Burlington, Ia., manufactures the Hawkeye refrigerator basket, Fig. 1. The latter is made of sheet metal covered with wickerwork to afford better insulation against exterior heat. The basket is divided into several compartments, one for ice, one for fluids and one for other refreshments.

Dewey Engine-Driven Pump

A new type of tire pump which fits into the spark-plug hole of the engine cylinders and which is operated by the engine suction and compression,. is the Dewey pump, Fig. 2. It consists of a pump cylinder 1 foot long and 2 inches in diameter, the bottom plate of which is equipped with a pipe connection threaded to fit into a 7-8-inch opening. Inside the cylinder is a piston which may be moved in the cylinder by air pressure against one of its sides and which is not fitted with any connecting-rod. Tightness against the cylinder walls is insured by a packing ring. The upper cylinder plate is perforated with a central hole and several holes disposed in a ring around the former. All holes serve as seats for check valves, the central one seating when the piston is drawn toward the engine cylinder by suction, while the other check valves seat when engine compression pushes the pump piston upward. This construction admits fresh air into the pump chamber above the piston on the engine-suction stroke and expels it through the central check valve and the tubing attached thereto by a compression coupling during the compression stroke. The compressed air forced out of the pump is transported through a flexible tube wound with a fabric to the tire valve. With this pump a flat 28 by 3-inch tire can be inflated to 60 pounds in about 3 minutes. This automatic tire pump is made by the Dewey-Anderson Company, Toledo, O., and is sold in the East by the Lowe Motor Supplies Company, Fifty-fifth street and Broadway, New York City.

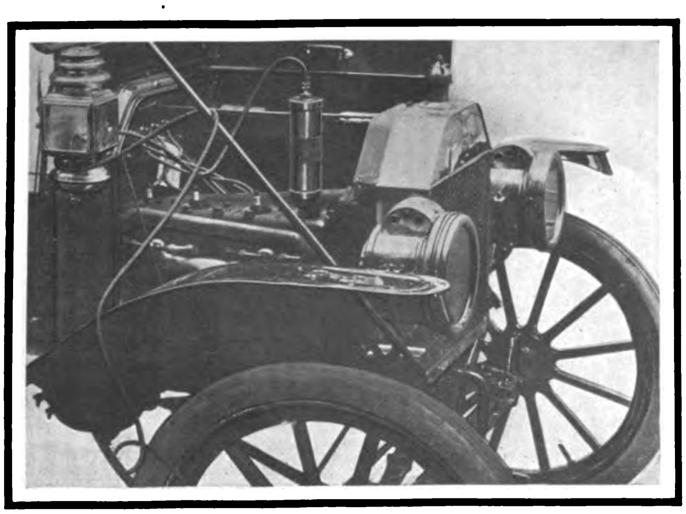


Fig. 2—Showing method of attaching Dewey tire pump

Mondex Acetylene Lighting

Most recent among the additions to the lighting-system field is the Mondex outfit of the Aristos Company, 250 West Fifty-fourth street, New York City. This system is of the acetylene type and is entirely controlled from the driver's seat, the turning of a knob admitting gas to the lamps and that of a small crank switch producing a series of sparks between the igniter points over the lamp burners. As Fig. 3 shows, the outfit consists of the dash fixture D which combines the office of acetylene admission valve and switch, of a reducing valve V which is attached to the gas tank, of a spark coil and of one igniter above each of the burners. The magneto may be used in place of battery and spark coil.

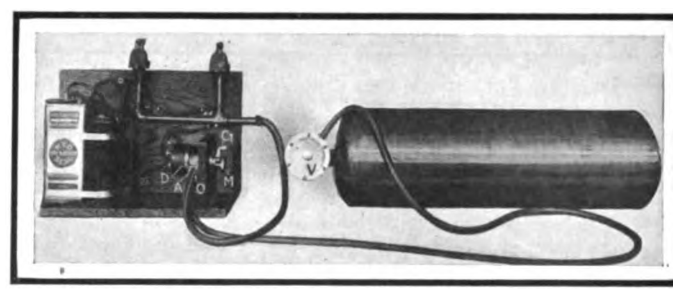

Fig. 3—Tank and control of Mondex lighting system

The construction of the component parts is illustrated in Fig. 4. V1 is the half of the regulator valve which is connected to the tank outlet and V2 is the other half. The mechanism contained inside the shells V1 and V2 consists of the grooved needle N, the levers L1 and L2, the circular fabric F and brass plate B, and the spring S which rests in the central recess of the part V2. The needle N seats in the central opening N1 of V1 which is attached to the outlet of the gas tank and its flat end bears against the lever L1 which is hooked to L2, the latter being attached to the plate B. The spring S presses against the other side of the plate B and its tension is regulated by the knurled screw K on V2. As the gas comes out of the tank and lifts the valve, the pressure inside V rises and tends to press the brass diaphragm against V2, being resisted to a degree varying with the adjustment of the spring S. At the same time, as the diaphragm moves away from V1, it draws with it L2 and thereby presses the pivoted lever toward V1, tending to press the needle N against its seat and limiting the quantity of gas leaving the tank to the amount determined by the adjustment.

The dashboard fixture of the system is shown in detail in Fig. 4. The gas-valve part consists of a steel needle bearing against a brass seat and ending in the knob M, Fig. 3, where A shows the admission, and O the outlet port, of the acetylene passing through the dashboard fixture. The electric part of this device is the switch S1, Fig. 4, which consists of a connector piece C, mounted on an insulation and turnable by means of the small crank C1, Fig. 3. The connections for directing a spark to the igniters at the burners may be made so that either the battery or the magneto serves as a source of current. If the battery is to be used, the wire leading from the battery is connected to the terminal marked 1 and the igniter is connected to the terminal marked 3, the negative battery and igniter terminals being grounded. With this wiring, if the switch is turned the piece C is brought to a horizontal position and closes the circuit with the coil in line and produces a series of sparks at the igniters. When the current for the sparks is to be taken from the magneto, 2 is connected to the spark-plug of one cylinder, the current normally passing through 1, the piece C and 2. If the crank C1 is turned, the magneto current is sent through the igniters instead of the spark-plug it normally serves; in this case no induction coil is used. The igniters I are simple in construction, the wires entering at the bottom of the insulator B1.

A New Eclipse Channel Bumper

The Emil Grossman Company, 250 West Fifty-fourth street, New York City, has brought out a new type of spring bumper,

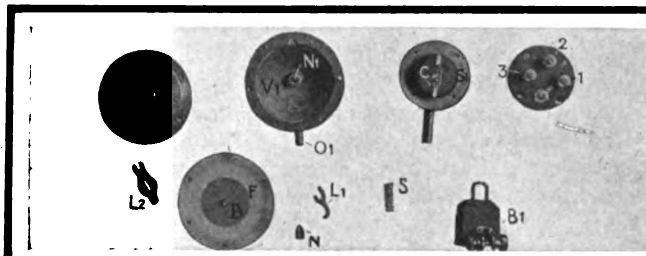

Fig. 4—Detail of Mondex dash control and switch

named the Eclipse. The bumper is made of steel throughout, the bar being of 2-inch solid stock and shaped as in Fig. 5. The attaching pieces are of stamped steel. The latter parts consist each of a short connecting bar support C, one end of

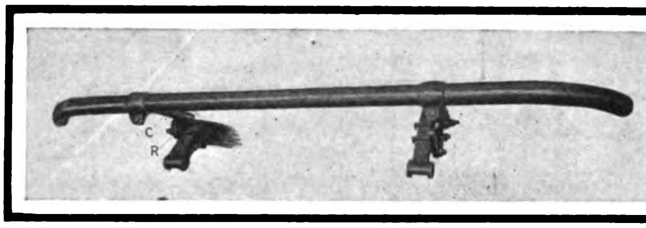

Fig. 5—New type of Eclipse steel spring bumper

which is attached to the bumper bar while the other is formed as a triangular plate with one edge shaped with ratchet serrations R which engage similar serrations on another triangular plate. Both plates are slotted to permit of passing through them three bent steel bars which are bolt-threaded at their outer ends. These bolts grip the channel of the frame side member with their bent ends, while nuts are placed on the bolt ends and there are so tightened as to give rigidity.

The Glover Rear Tire Holder

To make possible the attachment of tires to the rear of such cars as are not designed with provisions for this end, the Glover Manufacturing Company, 250 West Fifty-fourth street, New York City, has designed the tire holder, Figs. 6, 7 and 8. This tire holder is made of steel bars and is attached to the rear cross-member of the chassis frame by means of four bolts. In order to hold the tire in position on the car the holder arms A1 and A2 are fixed to each other by the supports penetrating the triangles T, one of which is riveted to each A1 and A2. The supports are attached to the chassis. The third arm A3 slides between the triangles attached to A1 and A2. A passage is cut out along most of its length, this passage being formed by a series of circles having part of one another's area in common. A bolt B passes through a hole in each triangle and through one of the circles of the passage cut in A3; one end of the bolt carries a head while the other is bored with a hole through which the hook of a padlock is passed. The four supports S1, S2, S3 and S4 are both fixed to the triangles and the chassis member by nuts holding the whole system tight. To prevent rattling at the points of attachment to the chassis, the ends fixed to that member are threaded in two ways, right-handed at the end and left-handed a small distance from it. On each support end a nut is fixed in front and one in back of the chassis channel, being spaced by an iron sleeve and prevented from coming loose by recesses inside the nuts. Owing to the movability of A3, any size of tire may be carried.

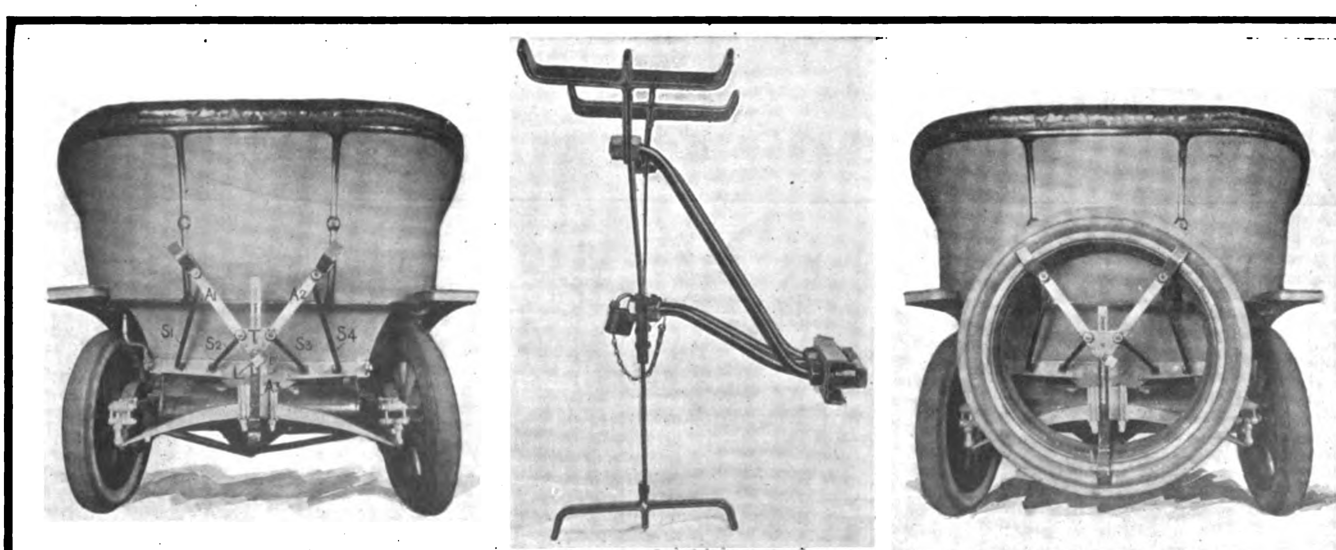

Fig. 6—Detail of Glover rear tire holder. Fig. 7—Side view, showing method of attaching. Fig. 8—Holder in place

HEADLIGHT Adjuster for Automobiles—Comprising connecting-rods and leverage whereby the headlights are always turned in the direction of the front wheels. This patent relates to a mechanism as shown in Fig. 1, where G is the cross-rod of the steering gear. Two lamps are carried by the supports S S. The connection between the lamp supports and the steering equipment is by means of the lever L which, at its middle portion, is connected to the front axle, and at one end to the steering apparatus, while its other end is linked to the rocker arm R. The lamp supports are connected by a rod C. and a rod R1 has one end secured to the rod C, and the other to the second end of the rocker arm.

No. 1,032,309—to Pembroke N. Squires, Cañon City, Col. Granted July 9, 1912; filed August 5, 1911.

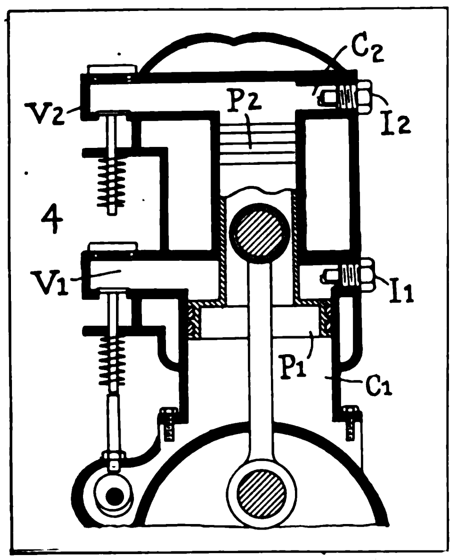

Fig. 4—Moertzsch's internal combustion motor

Differential Gearing Construction—In which the connection between gear casing and axle sections may be broken by the movement of a lever system controllable by the driver.

This patent describes a differential gearing, Fig 2, which operates in combination with a divided axle and which includes a casing D provided with teeth at its ends. Collars C are slidably mounted on the axle section A1 and A2 and their ends are provided with teeth adapted to engage those on the casing D. Keys fixed to the axle sections engage the collars, and slidably mounted pins P carry depending arms which engage the collars. Means B are provided for moving the pins within the supports and thereby engage or disengage the teeth on the casing D with those on the collars. To the casing D a gear wheel G is fixed which is driven by a pinion P1.

No. 1,032,261—to Elmo L. Wright and Thomas M. Biossat, Jr., Lafayette, Ind. Granted July 9, 1912; filed October 20, 1911.

Vehicle Supporting Device—Comprising rods and guides therefor which permit a suitable way of mounting pneumatic suspension members on the running-gear.

In Fig. 3 is illustrated the subject of this patent which refers to the combination of a body-frame, an axle and a pair of running-stress transmitting devices. One of these devices is located at each side of the body-frame and is interposed between the same and the axle. Each device consists of a pair of rods R held in alignment by guides G, the latter being connected by yokes Y. Body-supporting pneumatic cylinders C are pivotally connected to the yokes, being interposed between the yokes and the axle. One of the running-stress transmitting devices is pivotally connected to the axle in such a way that endwise movement of the axle relative to the frame is prevented, while the other device is so connected to the axle as to be capable of lengthwise movement relative to the same, permitting of free endwise tilting of the axle.

No. 1,031,759—to George Westinghouse, Pittsburgh, Pa. Granted July 9, 1909; filed October 15, 1910.

Internal-Combustion Motor—Cylinder and piston are worked with two portions of different diameters, permitting of alternate explosions in the cylinder portions.

The subject matter of this patent is an internal-combustion motor, Fig. 4, the cylinder of which has a wider and a narrower portion C1 and C2, into which fit piston portions P1 and P2. Above the end of each cylinder portion the cylinder expands into a lateral chamber in which the valve chambers V1 and V2 are contained, each being equipped with an inlet and an exhaust valve. Communicating with the lateral chambers are ignition devices I1 and I2. Means are provided whereby the sets of valves are operated alternately, and whereby alternate explosions in the combustion chambers C1 and C2 may be produced. This design and the mode of operation made possible by it results in twice as many power strokes on each crankpin as if an ordinary engine design were used. The consequence is that the running of the motor using cylinders of this design is equalized.

No. 1,031,809—to Hans Moertzsch, Detroit, Mich. Granted July 9, 1912; filed May 9, 1908.

The Automobile

Wonderful Growth of the Industry

First 6 Months of 1912 Witness Remarkable Increase in Number of Cars Turned Out by American Factories, Especially in the Low-Priced Class—Registrations Grow Proportionately—Exports Also Gain

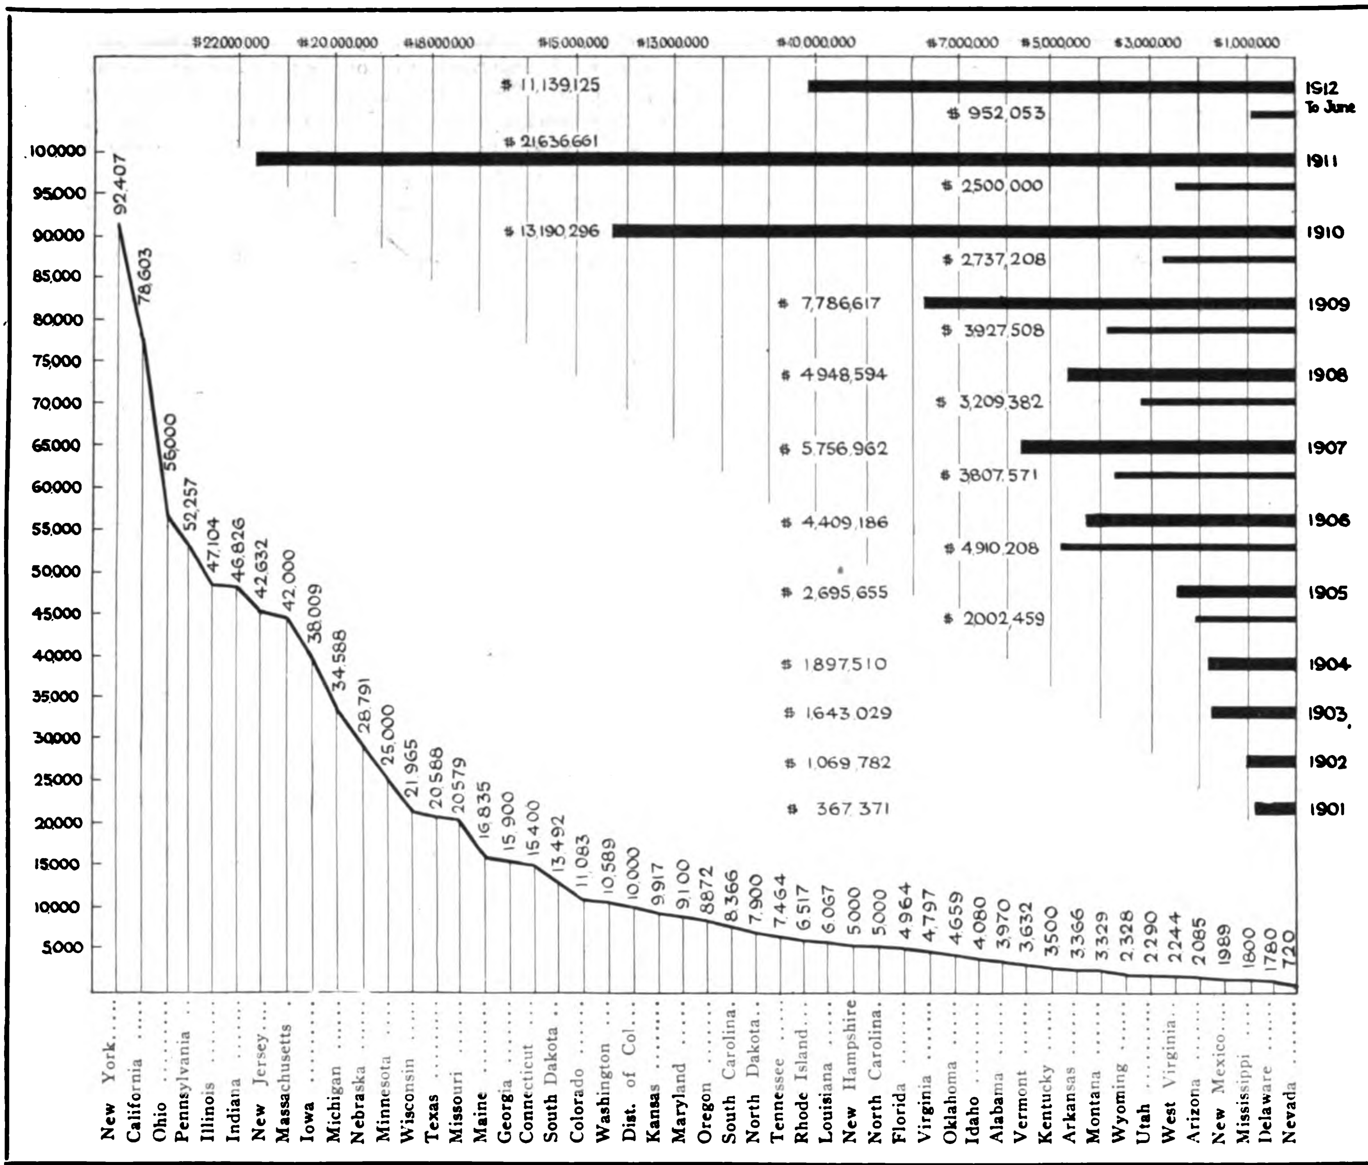
Total Registration, January 1 to July 1	859,858
Per Cent. Increase Over Entire Year 1911	18.8
Truck Registration, January 1 to July 1	31,574
Per Cent. Increase Over Entire Year 1911	24.0
Total Amount Received in Fees, Etc.	$4,769,873.29
Per Cent. Increase Over Entire Year 1911	19.6
Average Population Per Car in United States	110
Car Output, July 1, 1911, to July 1, 1912	252,569
Per Cent. Increase Over Calendar Year 1911	20.7
Value of 1912 Automobile Exports to June 1	$11,139,125
Per Cent. Increase Over 5 Months of 1911	23.5
Value of 1912 Automobile Imports to June 1	$952,053
Per Cent. Decrease from 5 Months of 1911	8.6
Automobile Companies Incorporated in 1912	801
Total Capitalization of New Companies	$136,956,740

EVER since the automobile became a common, everyday sight, and especially during the last few years when machines have come into general use in great numbers, people have indulged in more or less speculation as to the total number in operation on the streets and roads of the United States. Various guesses were hazarded, some of which turned out to be fairly accurate, while others were far below the figures given in The Automobile last winter after a careful and accurate census of the number of cars registered in every state in the Union. Everyone recognizes the fact that the automobile industry increased tremendously this spring, so The Automobile, in order to ascertain the output of American factories and the resultant sales, together with the registration figures during the past 6 months, has again taken a census of the manufacturers and of the state registration bureaus. The information resulting shows that American automobile makers built 252,569 cars of all sorts from July 1, 1911, to July 1, 1912, while the registrations have jumped to the amazing total of 859,988.

Since the conversion of New Jersey to reciprocity in exempting automobilists residing in other states from registration, the number of duplicate registrations, that is, the number of cars registered in more than one state, has been reduced to a very small number, so that it would be ultra-conservative to state that there are at present in use in the United States proper 850,000 automobiles, leaving 9,858 as the number of duplicate registrations. A table of the states, on page 161, alphabetically arranged, gives the number of registrations in each state up to July 1, together with the figures in each for the year 1911 and the number of new registrations. The table also gives the number of commercial vehicles registered at the present time, the number of electric pleasure vehicles and the total amount of revenue accruing to each state from automobile registration and chauffeurs' fees during the first 6 months of 1912. Special conditions obtaining in certain states, such as new automobile laws, lack of laws covering the registration and regulation of motor vehicles, perennial registration and local registration are mentioned as well.

In compiling this table nearly all the figures used in enumerating the pleasure cars were those given by the secretaries of state or other official in charge of the registration of automobiles, except in the case of those states in which there is at present no provision for automobile registration. In these instances it was necessary to estimate, and each estimate was made only after considerable research with references to the local conditions, population and the character of the business done by the car dealers during the past six months, care being taken to make each estimate reasonably conservative in view of the tremendous increase in the business reported from all parts of the country.

As shown by the chart on page 160, there is still a wide range of difference in the number of cars registered in the various states, New York retaining the lead with 92,407, having gained 8,438 cars since January 1, 1912. California, the next in line, shows a tremendous increase, jumping from 59,202 at the beginning of the year to 78,603 by July 1, a gain of 19,401. On account of her change of policy in regard to the registration of non-residents, New Jersey has dropped from third place to seventh with respect to the number of cars registered, Ohio moving up into her place from fourth place last winter, having increased 10,212 cars in the meantime, making her total registration 56,000. Pennsylvania has moved up one place in the line since last January, being fourth with a registration of 52,257 and showing an increase of 7,985 machines. Massachusetts, fifth in order last winter, has dropped to eighth place, being superseded by Illinois, with a registration of 47,104, a gain of 9,000. Indiana, with 46,826 cars, having gained 10,000, and New Jersey, which dropped from third place by decreasing in the number of cars registered from 48,266 to 42,632, showing that over



(Lower)—Curve representing total automobile registrations in the several states up to July 1. (Upper)—Values of automobile exports and imports from 1900 to June, 1912. The heavy lines indicating the exports and the lighter lines showing the imports

5,628 cars belonging to non-residents were not registered this year. There was an increase in the number of machines owned by residents of New Jersey as the dealers in that state report that business is good, so the number of non-residents taking advantage of the new conditions in the state must have been considerably in excess of the 5,628 decrease. Massachusetts follows New Jersey in eighth place with a registration of 42,000, showing a gain of 3,093 cars as compared with last winter's figures, while Iowa retains ninth place with 38,009 cars and an increase of 10,000, and Michigan is tenth again with 34,588 and a gain of 6,792. The other thirty-nine states and territories stand as shown in the illustration, the curve representing the number of cars registered sloping downward from Michigan's 34,588 to Nevada's 720. A number of the states have moved up the line in the past 6 months, passing others which have dropped to inferior places.

A very interesting feature of the situation with regard to the registration is the per cent. of increase in the various states. This is given in the table at the bottom of the left column on page 164 and is graphically illustrated in the chart at the top of the same page, showing the curve which represents the per cent. of gain in each state. A study of this will serve to discover a number of surprising facts with regard to the ratio of increase in the different states, and also giving an illuminating sidelight on the degree of the growth in prosperity of the states.

The average per cent. of increase in the registration of cars in the United States for the past 6 months was 24.6 as compared with 39.6 for the entire year of 1911 over 1910.

Maine's Increase Most Rapid

To the surprise of many, Maine leads the whole country in per cent. of increase in automobile registration, having added 67.5 per cent. since January 1, 1912. These figures substantiate the reports made during the spring as to the farmers buying cars with the proceeds of their potato crops. Five other states, Oregon, Mississippi, New Mexico, Delaware and Arizona, show increases of over 40 per cent., while nine more have added over 30 per cent. to their registration. The only state showing a decrease is New Jersey, which lost 11.7 per cent. in registration, or 5,268 machines, including over sixty trucks, in all probability those of the big New York and Philadelphia department stores, which, as non-residents, were not obliged to register under the new law. One of the surprising features of the study of the per cent. of increase is its regularity, as shown in the curve on page 164, Maine being the only state having a gain of over 50 per cent.

Another absorbing phase of the registration is the ratio of the number of cars registered in a state to the population. In this respect, the average obtaining throughout the country is one car to every 110 of the population. The standing of the states and territories with reference to this ratio is given in the table at the bottom of the right column on page 164 and is illustrated in the curve at the top of page 165. As shown in both the table and diagram, the District of Columbia stands first with one car to every thirty-five of the population. Nebraska and South Dakota come next with forty-five people per car, followed by Indiana, Iowa, Maine and New Jersey with sixty persons per car, and so on down the line, sixteen of the states having less than 180 people for each automobile, while twenty-one others have between 100 and 200 population for every car. The curve begins to sky-rocket right here, ending with Mississippi, which has 1,000 people for every automobile. The salient point about the curve is that it is so uniform throughout a large part of its length, pointing to a more even distribution of cars in proportion to the population than the registration by states would seem to indicate.

Trucks Show a Decided Gain

Commercial vehicles have increased considerably in number as was widely predicted last winter, the country's total jumping from 25,451 in December, 1911, to 31,574 by July 1, 1912. As in the case of the pleasure cars, New York State leads with a total registration of 7,977, as shown in the table on page 161. California keeps up her reputation by falling into second place with 3,180, while Massachusetts is a close third with 3,170. Then there is a big drop to Pennsylvania's 2,215 and the 2,100 trucks used in Illinois. Indiana and Michigan come next in line with 1,492 and 1,300 trucks, respectively. Then follow Ohio with 1,250, Iowa with 1,195 and Minnesota with 1,015.

In the electric pleasure car field, which comprises a total of 32,000 vehicles, New York is still the leading state, having approximately 6,000 of them in use. Ohio proudly bids for second place with 2,917 and Massachusetts shows her standing as an electric car state by displaying a total of 2,800, while California and Pennsylvania tie for fourth place with 2,500 apiece. Michigan and New Jersey tie for the next place at 1,500, followed by Indiana with 1,400, Minnesota with 1,200 and Wisconsin with 1,000. Thus it goes all the way down to New Mexico, which is credited with only ten electric pleasure cars.

The total revenue of the states from fees, etc., for the past 6 months was $4,769,873.29. The state making the most out of its automobile department since the first of the year is, of course, New York, whose revenue from this source totaled $941,347.25. Pennsylvania stands second, as shown in the table, with $525,679.43, while Massachusetts is third with $513,201.67 and New Jersey stands fourth in line with $369,062.04. Illinois automobilists have enriched her treasury to the extent of $305,520 in the same time, entitling her to fifth place in this respect. Ohio is sixth with $280,000, while Connecticut ranks seventh, having acquired $233,000 from her automobilists since January 1, 1912. Then there is a big drop to Minnesota, which is only $125,000 the richer for the automobiles within her borders, and to Michigan in ninth place with $119,000. Wisconsin stands tenth with revenues from her motorists to the extent of $109,825. The other states show revenues from the automobilists from $99,677 of Missouri to the $940 of Utah. Those states having no regulation for the registration of automobiles have no revenue from this source, of course, while those states in which the registration is a local matter are similarly situated, the fees generally going toward the improvement of the roads in the county in which the automobilist is resident. As the fees are usually devoted to the same end, however, in the states in which they go to swell the income of the state treasury, the result is practically the same. The states having no provision

as yet for registration and regulation of automobiles, namely, Idaho, Kansas, Montana, Nevada and New Mexico, are coming to recognize the value to the people of imposing a slight tax on automobiles in this manner, creating as it does a considerable sum each year for the betterment of the existing roads throughout the state and the building of new roads as the need arises. It will not be very long, in all probability, before these states will pass laws bringing about a state of things very similar to that now existing in other states in this respect. The automobilists will not object, even though it puts them to a slight increase of expense to be figured in the yearly upkeep of their cars, for they know that such a condition of affairs points to better roads and more roads throughout the state, which, for them, means increased pleasure and comfort as well as a wider radius for short tours. Those states which at present have laws which do not provide for yearly registration, that is, where a single registration suffices for all time, show some indications of preferring the yearly registration system with its accompanying increase of revenue and corresponding improvement of the highways, so that they, as well as the states which do not register cars at present, will conform to the more general practice.

Registration Increase, 19.7 Per Cent

To increase the registration throughout the United States in such a marked degree as the figures indicate, the sale of automobiles must have been enormous in the past 6 months. And, naturally, in the logical course of reasoning, this means a greatly increased production of cars. In order to determine the extent of the output of automobiles by American factories during the year ending July 1, 1912, THE AUTOMOBILE sent letters to every automobile manufacturer in the country, requesting information as to the number of pleasure cars and the number of commercial vehicles turned out by him during that period. Nearly all of them answered, giving the desired information, and in the cases of the others, agents and dealers were able to give approximate information as to the total production for that time. When the figures thus secured were totaled, it appeared that American manufacturers produced 252,569 self-propelled vehicles from July 1, 1911, to July 1, 1912. These consisted approximately of the following:

Gasoline pleasure cars	228,369
Gasoline trucks	16,500
Motor fire apparatus	700
Electric pleasure cars	6,000
Electric trucks	1,000
Total	252,569

At first glance, this number may seem tremendous, but, when compared with the output of American-built cars in the year 1911—209,957 cars—it seems well within reason, the makers having predicted an output of 247,427 for the year 1912. The 252,569 represents half of 1911 and half of 1912, so it looks as if the makers are keeping their promise, though, of course, that cannot be determined until the end of the year.

An interesting side to the output total is the fact that a larger percentage of it than ever is made up of small, low-priced machines, two companies alone turning out over 80,000 cars during the year from July 1, 1911, to July 1, 1912. This also has another effect on the situation, that is, with reference to the average price of the American-built car. As shown in the chart on page 165, this has been steadily declining ever since 1907, the year in which it attained its highest level, $2,137.56. Last year it was $1,245.99, and this year it has dropped to $1,083.10. The small cars form the bulk of the automobile exports of the country, the average price of the cars exported during the past 6 months being $977.98. The difference in the average price caused by the wide use of the higher-priced cars in the United States is significant.

The enormous output of the small machines as compared to the larger ones points out another interesting fact. This is the

Total automobiles, and parts of	....	$3,936,508	....	$2,737,208	....	$2,446,248	....	$952,053

degree to which the American automobile factories have become organized, systematized and standardized so that everything works along smoothly, resulting in a large output, which, however, is not of a spasmodic character, in spite of its magnitude.

The last 6 months have been very busy ones for the industry, almost every factory in the field doing something with a view to either increasing its capacity or bettering its appointments and equipment. A great many of them have been putting up additions, some large enough to double the former capacity of the establishment, while others have built or leased new factories, finding their previous quarters too small for their rapidly increasing business.

Many Companies Incorporated

The number of companies incorporated in the last 6 months for the purpose of manufacturing and selling automobiles and parts and for renting automobiles, running motor truck and bus lines, conducting garages and repair shops and manufacturing and selling accessories—801—gives a fair idea of the activity in the field since the first of the year. The total number of those incorporated during this period as intending to manufacture and sell automobiles and parts is 449, while the others amount to 352. The total capitalization of these companies is $136,956,740, the capital of those formed to make and deal in cars and parts aggregating $70,291,700, while that of the other concerns is $66,665,040. It is interesting to note the variation in the incorporations from month to month, as shown in the following tabulation:

Month	Automobiles and parts	Capital	Garages etc.	Capital
January	71	$8,856,500	38	$2,578,500
February	90	9,231,500	75	4,613,000
March	59	9,258,100	55	2,966,500
April	79	11,902,600	72	4,593,000
May	89	21,224,000	75	50,134,600
June	61	9,819,009	37	1,779,440
Total	449	$70,291,700	352	$66,665,040

This gives an average of 134 incorporations per month, with an average capitalization of $170,982.19. Of these, seventy-five companies were incorporated a month on the average to make

and sell automobiles and parts, with an average capital of $156,551.67, together with an average of fifty-nine other companies connected with the automobile industry having an average capitalization of $189,389.31

The United States has settled into first place as the leading automobile-exporting nation of the world, the value of the exports of automobiles and parts from our shores to foreign countries steadily increasing, while the value of the imports is correspondingly decreasing. As shown in the chart on page 160 and in the tables on page 162, the value of the exports for the first 5 months of the year 1912 was $11,139,125 and the value of the imports for the same period $952,053. In comparison with the figures for the entire year of 1911 the above figures show a large increase, as the total valuation of the exports in that year was $21,636,661. The value of the imports for 1911 was $2,500,000, which, when contrasted with the figures for the first 5 months of this year, given above, plainly show the rapid rate at which importation is decreasing. If this present rate of decrease continues, and there is no reason why it should not, the total value of the imports at the end of the year 1912 will be $600,000 less than at the end of the year 1911. On the other hand, the value of the exports will probably touch $25,000,000.

Great Britain Takes Many Cars

As shown in the tables on page 162, the value of the exports to the United Kingdom for 1912 up to June 1 is $2,476,917 against $3,380,266 for the entire year of 1911. The value of the imports from the United Kingdom amounts to $183,271 for the first 5 months of 1912, while they amounted to $403,506 for the whole 12 months of 1911.

Curve indicating ratio of population in the several states to the number of automobiles registered up to July 1

During the first 5 months of this year the value of the automobiles exported to France was $212,094 up to June 1, and the figure for 1911 was $449,757. More cars are imported to the United States from France than from any other country, it being the only country besides Italy whose imports have increased proportionately in the first 5 months of 1912 to the entire year 1911. The value of the imports from France up to June 1 of this year was $471,703 as compared with $770,643 in the whole of 1911. The most remarkable increase in our exportation has been made in our commerce with Germany, to which country automobiles valued at $132,663 have been exported during the first 5 months of 1912, while the exports to that country during the 12 months of 1911 were valued at only $124,615, an increase of $8,048. A comparison of the number of cars shipped to Germany during the first 5 months of 1912 and the 12 months of 1911 show plainly that the lower-priced American cars are finding a growing market in Germany, as the number of automobiles exported in 1911 was 115 and up to June 1, 1912, there were 187 cars, an increase of 72. Correspondingly, the importation of automobiles from Germany show a great falling off, the value of the cars imported up to June 1 of this year being $60,222 and the number of cars being 27, while in 1911 the entire importation amounted to $350,239 and the number of cars was 160.

Canada Gets Bulk of Our Exports

The exports to Italy up to June 1 amounted to $93,772 and for 1911 they were valued at $199,986. The imports from Italy in 1912 up to June 1, however, have increased by $129,385 over the total imports from that country in 1911, as the valuation of this year's importation is $333.118 and in 1911 it was $203,733 for the entire year.

Canada maintains the lead of foreign countries using American cars and the value of our exports to that country for the first 5 months of this year falls short of the figures for the entire year of 1911 by only $1,783,825. Our exports to Canada during 1911 were valued at $5.549.998 and in the first 5 months of this year the value of the automobile exports was $3,766,163.

In 1912, $704,417 worth of machines built in the United States were exported to South America up to June 1, while, in the whole year of 1911, $1,356,445 was invested by the people of that continent in our motor cars.

It is the lower-priced American cars that have the largest foreign market, because, as a general thing, the foreigner who can afford to buy a higher-priced car is satisfied with the product of his own country. Recently the lower-priced American automobile has been gaining favor abroad, as is evidenced by the fact that the average price of the exported cars has dropped from $1,000.70 in 1911 to $977.98 in the first 5 months of 1912.

The value of the tires exported from this country increased from $1,838,482 in June, 1911, to $2.335.920 in May, 1912, or $497,438.

That American-made automobiles have established themselves firmly on foreign soil is clearly shown by the tremendous increase in the value of the cars exported from this country in the past 10 years. As will be seen upon referring to the upper right of the chart on page 160, the value of the cars and parts exported in 1901 was only $367,371, while in 1905 this business amounted to $2,695,655. In 1905, which is the first year for which any importation records are available, they were valued at $2,002,459. In the following year they reached their highest point at $4,910,208, and the exports for that year were $4,409,186. After 1905 the imports fluctuated very much, but the exports continued to gain steadily. In 1909, the exports reached $7,786,-617 and the imports touched their second highest figure, $3,927.508, but one year later the imports had lost almost 100 per cent., while the exports had gained almost the same amount. In 1911 the imports dropped to $2,500,000 and the exports jumped to $21,636,661. Up to June 1, 1912, the value of the exports was $11,139.125 and the imports were valued at $952,053. With 7 months of this year left after these figures were compiled, in which to carry on business, it is safe to predict that the value of the exports for 1912 will reach $25,000,000.

Legal News of the Week

Enterprize Automobile Company Wins Suit in Which Infringement Against Dyer Patents Was Claimed

Bergdoll Appeals $104,000 Judgment in Favor of Westinghouse—Ford Enjoins Price Cutters

LETTERS patent 921,963 and forty claims set forth in letters patent 885,986 were sustained and declared to be valid and infringed in the suit brought by the Enterprize Automobile Company of Hoboken, N. J., against Albert Solvay, a Brooklyn liveryman, owner of two Darracq cars by Judge Van Vechten Veeder in the United States District Court for the Eastern District of New York.

The patents in suit were the Dyer patents covering an automobile vehicle and a selective type of transmission.

Proof of the patent was made and a defense was filed on behalf of Solvay. The final argument was made June 10 and the matter has been in the hands of the court since that day.

The interlocutory decree awarding an injunction, accounting and damages is as follows:

At a Stated Term of the United States District Court for the Eastern District of New York, held in the Post Office Building, Borough of Brooklyn, on this 19th day of July, 1912.
Present:

HON. VAN VECHTEN VEEDER, UNITED STATES JUDGE.

ENTERPRIZE AUTOMOBILE COMPANY, Complainant,
vs. } In Equity.
ALBERT SOLVAY, Defendant.

INTERLOCUTORY DECREE.

This cause having come on for final hearing on the pleadings and proofs herein, now, on consideration thereof and after hearing John Robert Taylor, Esq., of counsel for the Complainant, and on motion of Dyer, Dyer & Taylor, Solicitors for the Complainant, it is

ORDERED, ADJUDGED and DECREED as follows, to wit:

1. That United States Letters Patent No. 885,986, granted April 28. 1908, to Leonard H. Dyer, for Transmission Gear for Motor Vehicles, and United States Letters Patent No. 921,963, granted May 18, 1909, to Enterprize Automobile Company on the application of Leonard H. Dyer, for Automobile Vehicle, said patents being the Letters Patent in suit, are good and valid Letters Patent; that the said Leonard H. Dyer was the original and first inventor of the inventions described in said Letters Patent; that the Complainant, Enterprize Automobile Company, above named, is now, and continuously since the 18th day of May, 1909, has been possessed of the entire legal right, title and interest in and to the said Letters Patent 921,963, and in and to the inventions covered thereby, and is now, and continuously since the 21st day of September, 1908, has been possessed of the entire legal right, title and interest in and to the said Letters Patent 885,986, and in and to the inventions covered thereby.

2. That the Defendant, Albert Solvay, has infringed upon each and both of said Letters Patent, and upon the exclusive rights of the Complainant under the same, by using and selling automobile vehicles constructed in accordance with the inventions of said Letters Patent 921,963 and all three claims thereof, and transmission gears for motor vehicles constructed in accordance with the inventions of said Letters Patent 885,986 and claims 1 to 17 inclusive, 20 to 31 inclusive, 46, and 48 to 57 inclusive thereof.

3. That the Complainant recover from the Defendant, Albert Solvay, the profits, gains and advantages which the said Defendant has received or made, or which have arisen or accrued to him by reason of any infringement of each and both of the said Letters Patent, together with the damages which the Complainant has sustained by reason of such infringement.

4. That this cause be referred to .... specially appointed as Master by this Court by reason of his experience in such matters, to ascertain and take and report to the Court an account of the said profits, and also the amount of damages sustained by the said Complainant from said infringement; that the Complainant upon said accounting have the right to cause an examination of the Defendant, Albert Solvay, and his servants, agents, attorneys, employees, workmen and confederates, *ore tenus*, or otherwise and also to cause the production of the books, vouchers and documents of said Defendant, and that the said Defendant and his servants, agents, attorneys, employees, workmen and confederates attend for the purpose of such accounting before said Master, from time to time, as he shall direct.

5. That a perpetual injunction be issued herein against the said Defendant, Albert Solvay, and his servants, agents, attorneys, employees, workmen and confederates, and each and every of them, enjoining and restraining them and each and every of them from directly or indirectly making, constructing, using, vending, delivering, working or putting into operation or use, motor vehicles like or similar to those which the said Defendant has heretofore made or used, or sold, in infringement of either or both of the aforesaid Letters Patent, and from directly or indirectly in any manner counterfeiting or imitating the inventions of Letters Patent No. 921,963, and claims 1 to 17, inclusive, 20 to 31, inclusive, 46, and 48 to 57, inclusive, of Letters Patent No. 885,986, or upon the rights of the Complainant under the same.

6. That the Complainant recover of the Defendant its costs, charges and disbursements in this suit to be taxed, and that the Complainant have execution therefor forthwith.

VAN VECHTEN VEEDER,
United States Judge.

The seventeen claims of patent 885,986 which were not covered, or which were not mentioned in the decree are as follows: Claim 18 covers a phase of reduced speed gearing that is disconnected when not in use. Claim 19 is the same except that includes a reversing gear. Claims 32 to 45 deal with details of operation, 47 is for a means for directly connecting the driving and driven shafts with all intermediate gears at rest. The seventeen claims were not in issue so far as appears on the record.

While the court went to considerable length in considering the case, the defense that is promised when the same patents are tried out in the basic suits against the Maxwell, Winton, Locomobile and Saurer companies will be much more elaborate and detailed.

Bergdoll Appeals Big Judgment

PHILADELPHIA, July 22—Judgment of $104,000 in favor of the Westinghouse Machine Company rendered last week by Judge Audenried in Common Pleas Court in a suit against the Louis J. Bergdoll Motor Company, has been appealed by the latter.

The dispute arose over differences regarding the terms of a contract entered into about 3 years ago for the manufacture and delivery of 1000 motors by the Westinghouse Company, to be delivered within a specified time to the Bergdoll Company.

Officials of the Bergdoll Company today outlined their side of the case substantially as follows: Back in 1910, shortly after the organization of the Louis J. Bergdoll Motor Company, a contract was entered into with the Westinghouse Machine Company for the furnishing of 1000 gasoline motors to be used in the building of the Bergdoll 30. These motors were to be furnished in specified allotments as required. Over half the number were manufactured and delivered before the trouble began. Then the defendant company contends that a hitch occurred in the delivery of the balance—about 450—around which the suit revolves. In this contention the Bergdoll Company complains that it lost money in unfilled orders owing to the failure of the plaintiff to furnish the motors with which to equip the cars, the company being unable to keep pace with sales. In the meantime to avoid future complications the Bergdoll Company established a shop and began the manufacture of its own motors, not only for the 30, but also all other models and refused to accept the 450 when completed, claiming justification for the refusal on the grounds that the machine company had not delivered the remainder of the motors at the agreed-upon time. This contention was decided as being without merit by the Court.

Judge Audenried in rendering decision said that the Westinghouse Company was not bound to find a market for the motors the Bergdoll Company refused to take, and awarded the former concern the amount due on the balance of unaccepted motors.

Injunctions Against Price-Cutters

BUFFALO, N. Y., July 22—Judge Hazel late this afternoon granted a temporary injunction to the Ford Motor Car Company restraining the International Automobile League of Buffalo, composed of John H. Tranter, Alfred C. Bidwell, William Priess and John C. Hurley, from selling Ford automobiles at less than the standard price, infringing on Ford patents and from federating with the dealers to procure machines at less than cost. The officials of the International Automobile League of Buffalo are ordered by Judge Hazel to appear in court on Tuesday, July 30, to show cause why the injunction should not be made permanent and also to appear before him the first Monday in September in reply to the bill of complaint.

A perpetual injunction has been granted by the United States District Court against Bloomingdale Brothers, a New York department store, forbidding the company to sell Mosler sparkplugs at less than list price.

A suit of the same general character as the above has been entered on behalf of A. R. Mosler & Company against the Auto Surplus Stock Syndicate and William Wooster, its president.

Thropp Patent Is Invalid

Court Holds Tire-Making Machine Was Anticipated by Fisk Device—Mais in Receiver's Hands

Case Companies in Peculiar Legal Tangle—DeTamble Creditors File Bankruptcy Petition

BOSTON, July 20—Judge Brown of the United States District Court of Massachusetts has given his decision in the case brought against the Fisk Rubber Company of Chicopee by the De Laski & Thropp Circular Woven Tire Company, in which he dismissed the bill brought by the latter company. The opinion was rendered July 16 at the Federal building in Boston. The judge in his opinion says:

The bill alleges infringement of claims 1 and 2 of letters patent No. 822,561 to P. D. Thropp for apparatus for manufacturing wheel tires. Application was filed November 1, 1905; the patent is dated June 5, 1906. The invention relates especially to apparatus for holding a clencher tire in position during the vlcanizing process.

1. Tire forming apparatus comprising an annular core or mandrel, annular pressure rings arranged to engage the clencher edges of the tire, leaving the outer body portion of the tire exposed and means for forcing the pressure rings into a predetermined position with respect to the core or mandrel.

2. Tire forming apparatus, comprising an annular core or mandrel provided with an inwardly extending rib, pressure rings arranged to engage the clencher edges of the tire on opposite sides of said rib, leaving the outer body portion of the tire exposed and means for forcing the pressure rings against the opposite sides of the rib.

Complainants say the invention lies in the apparatus for molding and giving pressure to tire casing during the vulcanization; that the apparatus is adapted for use in producing automobile tire casings by what is called the "one cure, wrapped tread method," in which the inner casing, including the tread, is built upon a core or mandrel at one time of green or unvulcanized stock. The side pressure rings are then applied, which inclose the inner or clencher part of the tire, leaving the outer body portion unenclosed. The whole is then spirally wrapped with a porous tape, and so is submitted to a vulcanizing heat, after which the wrapping, pressure rings and mandrel or core are removed and the casing is entirely completed. Complainants state that many advantages result from the use of this apparatus, both in the quality of the product through the avoidance of pinching or of buckling, which is said to attend the use of the full or closed mold of the prior art, by reason of the difficulty in estimating accurately the amount of rubber necessary for the proper filling of the closed mold, and in the ease, speed and lessened cost of manufacture. It is claimed that the patent in suit is basic, being the first apparatus adapted for the manufacture of one cure, open cure, wrapped tread tire casings, in which substantially the inner half of the casing (that is, the clencher part) is molded, and the outer half open cured.

The utility of the apparatus is shown by the testimony to the effect that by July of the year 1910 nineteen manufacturers of automobile tire casings used this device and paid royalties therefor to the complainants. The most important defense is that of invalidity of the patent in view of prior patents and of the prior unpatented art. The defendant states that the Thropp patent shows an open mold as distinguished from a closed mold, and that an open mold is in all respects like a closed mold except that the outer edges of the mold sections are cut away to expose a part of the sheath. In both forms the mold must enclose and engage the clencher part of the sheath. The defendant has introduced a large amount of testimony as to devices of the prior art preceding Thropp's date of invention. Thropp claims as his date of conception February 1, 1905. In interference proceedings the patentee, Thropp, on March 2, 1907, filed a sworn preliminary statement in the patent office to the effect that he conceived the invention and first made a drawing or sketch of it about Feburary 1, 1905 that a full-sized working model was first disclosed to others on or about March 1, 1905; that a full-sized working model of the invention was made on or about July 15, 1905, and that he first reduced his invention to practice on or about July 20, 1905.

The defendant has produced voluminous evidence, called the Akron evidence, as to the making of designs for molds by the B. F. Goodrich Company, the manufacture of molds, and the use of these molds in January, 1905, for the manufacture of single-open cure wrapped tread automobile tires. It has also proved that the first four of these tires were delivered to the Baker Electric Vehicle Company, of Cleveland, Ohio, January 10, 1905. Drawings for an open heat mold dated December 22, 1904, are produced, which show a mold comprising a mandrel and annular pressure rings arranged to engage the clencher edges of the tire, leaving the outer body portion of the tire exposed; also open-heat molds for a fillet to be used in connection with the pressure rings.

In the patent in suit it is said:

"The outer edges of the pressure rings are made quite thick, as shown at 11 and 12, in order to make them firm."

Also the following:

"In operation, the several elements of the tire having been placed in position, on the core and the pressure rings forced into position by bolts 8, filling rings 17-18 of wedge shape in cross-section are placed against the sides of the tire above the thick edges 11 and 12 of the pressure rings, and the whole is wound with a wrapping of tape, the filling pieces 17-18 serving to impart the pressure of the winding tape to the sides of the tire to hold the latter in position during the vulcanizing process."

The fillet molds shown in the Akron evidence are for producing filling pieces corresponding to those shown in the patent in suit. The filling rings are elements of claim 3, but are not elements of claims 1 and 2. The omission of these wedged-shaped filling pieces from the apparatus of the patent in suit would leave a portion of the outer tread at a considerable distance from the winding tape, so that the winding tape would no exert its pressure upon parts of the outer portion of the tire. Nevertheless, the defendant has shown a device which in all substantial particulars is an anticipation of what is shown in the drawings of the patent in the suit, and which is doubtless apparatus for holding a clencher tire in position during the vulcanizing process in connection with a winding tape. If the claims in suit can be distinguished by the omission of the fillets, and cover apparatus in which the outer edges of the pressure rings are made sharper and longer so as to dispense with the use of fillets, this must be regarded as merely a difference in form which does not meet the defense that the prior art shows rigid mold section for the clencher or inner part of the tire adapted to be used with a cross wrapper for the curing of tire casings in open heat. * * *

It seems unnecessary upon the question of anticipation to refer specifically to devices other than the devices proved in the Akron defense further than to say that they thoroughly establish the fact that the single cure wrapped tread process was familiar in the art, and therefore that the patent in the suit cannot be construed with the breath that would be given to it if it were for the first apparatus which embodied this method of curing tires. It may, however, be properly considered upon the evidence in the case as for apparatus which comprehends rigid molds for the inner part of the tire, capable of exerting considerable pressure at that point, while leaving the outer part of the casing free for the open cure wrapped tread process. So considered I am of the opinion that it is anticipated by the production and use of substantially similar apparatus by the Goodrich Manufacturing Company, and that anticipation is not avoided by the fact that in the claims in suit the fillets are omitted. The lengthening of the edges of the pressure rings so as to obviate the use of fillets is not indicated in the specification of the patent in suit; and if the omission of fillets from claims 1 and 2 is sufficient to support the inference that the patentee had in mind a structure of other form than that shown in the drawings and described in the specification, it must be upon the view that such change was obvious. There is described in the patent in suit nothing patentable over the prior Goodrich structure, even if the claimant's pressure rings were so constructed as to obviate the use of fillets.

I am of the opinion that claims 1 and 2 of the patent in suit are invalid by reason of anticipation.

The bill will be dismissed.

Receiver for Mais Truck Company

INDIANAPOLIS, IND., July 22—On a suit brought in the superior court by Edwin King, Judge Collier has appointer Franklin Vonnegut receiver for the Mais Motor Truck Company. It is probable that steps directed toward the sale of company's property will be taken within the next 30 days.

King is a contracting builder who built a factory building for the company at a cost of $5,050 on which he has received $2,800. The suit was brought to protect a mechanics' lien against the property. King alleges the company is in danger of insolvency and has no money with which to conduct its business. He does not charge, however, that the company is insolvent at the present time.

At Odds Over Delivery of Mails

RACINE, WIS., July 22—The J. I. Case Threshing Machine Company, manufacturing Case cars, and the J. I. Case Company, the sales end of the J. I. Case Plow Works, of Racine, Wis., are engaged in a legal battle over the right to the delivery of mail. The threshing machine company has for many years received all mail addressed J. I. Case Company and when the plow works recently organized a subsidiary under the style of J. I. Case Company the matter was presented to the postoffice department which ruled that the delivery of all Case mail to the threshing machine and motor car company was proper and should be continued. The matter is now in the Circuit Court at Racine.

Receiver Named for De Tamble

ANDERSON, IND., July 22—John C. Teegarden, an attorney of this city, has been appointed receiver for the De Tamble Motor Company. The action was taken on a petition brought in the federal court in Indianapolis, alleging that the company is insolvent and has been paying certain creditors, thereby making their claims preferred. The creditors filing the involuntary bankruptcy petition were the Class Journal Company, Michelin Tire Company and St. Louis Screw Company, whose claims aggregate $5,476.32.

READING, PA., July 22—Final distribution to the creditors of the Duryea Power Company of this city has been made. The sum involved was $1,156, the principal claims being by Joseph Middleby and H. M. Sternburgh.

The United States Supreme Court heretofore decided that the claim of the Berks County Trust Company against Mr. Sternburgh for $26,000 on stock subscriptions was invalid and the aforesaid claim was the chief asset of the defunct company.

Part of the tour halting after climbing out of the Ohio River valley, opposite Wheeling, W. Va.

Business Results from The Four-States Tour

Novel Trip of the Indiana Manufacturers Brings Prospectives in Close Touch With Hoosier Product

On the bridge over Big Sandy

HUNTINGTON, W. VA., July 21—Afloat upon the Ohio River to-night are eight Indiana motor cars participating in the Four-States tour of the Hoosier manufacturers. At 3 o'clock to-morrow morning in tow of the old stern-wheeler "Tacoma," they will start down the muddy river to Maysville, Ky., a distance of about 100 miles.

There have been many interesting incidents in the week's sojourn in Ohio and the entrance into the country below the Mason and Dixon line. For example, there was the pleasantry in Newark when the tourists were arrested successively for throwing confetti, making undue noise and blockading the streets, followed by their leaving the city with much hilarity; there was the cloudburst between Circleville and Chillicothe, when the cars on ordinary roads ran through water up to their frames; then there was the experience of a red fire parade, with over 150 motor cars in line, in Portsmouth.

And as a climax to the week there was the passage through three sections of three states in the course of as many hours on Saturday, in running from Portsmouth to this city.

A week in eastern and southern Ohio brought to the Hoosiers much of business and at the same time numerous situations of unusual interest. It so happened that upon the day the Four-Staters arrived in Columbus there was the convention of the Federation of American Motorcyclists occurring, and for miles surrounding the Buckeye state capital the two-wheeled devotees were running. Over the old national pike from the east the Indiana automobiles and the New York, Pennsylvania and Maryland motorcyclists toured together.

During this run the tourists keenly felt the negligence of some authorities in permitting the fine old National Pike to disintegrate into the roughest roads experienced on the tour up to that point.

From Wheeling to Columbus the National road was a heart-breaker. It was only the skill of the Hoosier drivers that prevented a flock of broken springs. After the tour left Wheeling until it arrived in Zanesville there was not a half mile that was not punctuated with abrupt breakwaters. After the tourists left Zanesville they detoured to Newark from the National road at Mount Hebron and returned to it at Ætna. Between Ætna and Reynoldsburg there are 6 miles of road that even the far southwestern Indiana trails would put to shame. This road will not admit of a speed of over 5 miles an hour and is one chuck-hole after another about 6 to 18 inches in depth.

For the first time in the history of organized touring of motor cars a tour was abruptly ordered out of a city by one of its uniformed officers. When the confetti car Great Western rolled into this little Ohio city the pilot of the tour, W. D. Edenburn, was placed under arrest for strewing clean confetti over the seldom-swept brick streets of that city.

The pilot was released after some little detention in the city offices with a reprimand. Hurrying to the square, he warned the arriving tourists that arrest would follow the distribution of advertising matter, and the bluecoat, who so officiously arrested the pilot, then ordered the tour to move on as the cars were blocking the nearly deserted streets.

With the exception of this semi-humorous incident the hearty welcomes gladdened the hearts of the tourists. The Columbus club gave the tourists guests' cards and royally entertained them during their sojourn. Chillicothe, the old state capital, turned out en masse to see the cars parked on the public square. It was estimated by Portsmouth officials that more than 10,000 persons stood along the line of march during the red light parade. On arriving in Huntington the Mayor turned over the city to the Hoosiers and a banquet at the Guyandotte Club in the evening was preceded by a band concert in front of the official hotel.

The cars were loaded on three large barges this afternoon. The Indiana Automobile Manufacturers' Association built a trestle 70 feet in length to reach the barges and the cars were driven on. They will be unloaded at Maysville in the order of the line of march and proceed to Lexington

The dealers in the cities through which the tour has passed in the last 7 days have been much more interested than those on the first leg of the journey. The manufacturers are building up a wealth of prospective business and closing with several dealers. The dealers are bringing their prospects from miles around and the tour instead of losing ground is gaining as it nears the home stretch.

The tourists will leave Louisville at 9 o'clock July 24 and run to Columbus, where they will remain until 1:30 the next day, arriving in Indianapolis at 4:30. The cars will all be parked in the Circle around the Soldiers and Sailors' monument until 7:30, when the tourists, clad in their road costumes, will form and parade to the German House, where the festal board will be spread.

Wisconsin Reliability Had Dozen Starters

All But Two Finished With Perfect Scores—Business Features of the Run Not Very Successful

MILWAUKEE, WIS., July 22—Lack of interest, which might almost be called antipathy, on the part of motor car dealers in Milwaukee with regard to the third annual Wisconsin reliability tour of the Wisconsin State Automobile Association, which was run from July 15 to 19 inclusive, has probably ended the efforts of the state organization of motorists to promote endurance or reliability runs in the interest of the tradesmen. Yet in spite of the lack of interest, which resulted in a small entry list, the 1912 tour is regarded by the participating dealers as one of the best business promotion stunts they have ever experienced, and satisfaction is expressed all along the line. The twelve distinct makes of cars which covered the tour have made many new acquaintances among dealers and prospective buyers, and they have injected new enthusiasm into present owners, the three forces being important vertebræ in the backbone of the motor industry.

Ten out of twelve starters in the competition for the sweepstakes trophy, The Milwaukee *Sentinel* cup, finished with perfect scores; one carried a demerit of 39 points for a minor repair, while the other was withdrawn because of trouble which while not serious would have loaded a heavy penalty on the car because of the point-per-minute demerit rule for work on the road. Both contenders for the Emil Schandein cup, for private owners, finished with clean slates.

The penalty of 39 points on No. 3 King was imposed for work on the water manifold. Driver Hanneman had difficulty in keeping water in his radiator and on investigation found that the packing had slipped out of place. He consumed 39 minutes in making a repair that he was sure would last.

The Flanders roadster was forced to drop out at Shawano, Wis., on the fourth day because of bearing trouble in the differential. Its team-mate, a Flanders touring car, came through with a clean score, although its load weighed 665 pounds.

Only once did the tourists strike rain. On leaving Oshkosh on July 18, a drizzling rain set in, which turned to a heavy shower by the time Appleton was reached. Five miles west of Appleton the sun was shining and no more rain was encountered.

The main purpose of the tour was business. But no tour with such a purpose could possibly hope to induce the interest without the competitive feature, for people nowadays know motor cars when they see them and they will not walk a few steps to look at an outside car unless it is decorated with a contestant's number, a bunch of pennants and banners, and contains a party of tourists.

The principal argument used by the executive committee of the W. S. A. A. when it sought entries was that it had laid out regulations which would permit of demonstrations in the various towns and cities, conferences with dealers during the short stops between controls, and time to book orders in case an enthusiast was ripe for this important proceeding. It can be said that while the association made good on its promises, the contestants did not nearly take advantage of the opportunities afforded. A careful watch of the contestants during the 5 days revealed the fact that only 50 per cent. of them cared to take advantage of the possibilities. Talks with the other half indicate that they did just as much promotion work as they intended to at the start, so everybody seems satisfied.

R. D. Rockstead, of Milwaukee, state agent for the little Paige car, utilized the opportunity for business to the full. He contracted for nearly fifty Paige cars.

A few of the contestants did elaborate advertising by means of souvenirs, pennants or other novelties. The Marion distributed several thousand mirrors; the Case distributed 5,000 stickpins of the famous Case eagle; the Paige pinned 1,500 small pennants on as many people. The Milwaukee *Sentinel*, donor of the sweepstakes prize, distributed 5,000 small pennants and 1,000 large pennants bearing the words, "Milwaukee Sentinel Trophy Tour 1912." The Rambler people, who furnished the press car, gave away 5,000 neat badges of brass and enamel. Approximately 75,000 dodgers advertising the Grand Prix, Vanderbilt and other road races at Milwaukee, September 17 and 21, were distributed over the route. The promoter of the speed carnival, the Milwaukee Automobile Dealers' Association, was represented in the tour by two members.

Dealers in all towns and cities are enthusiastic. Prosperity simply bristles everywhere. The garages that two years ago were dilapidated barns and sheds are to-day fine concrete or brick business houses—real garages. These men are confident of the future and can see nothing in the situation to discourage them in the least. More than half of the dealers with whom conversations were held said they could have sold more cars during the closing season if the state agents or factories could have supplied them. They have increased their 1913 demands all the way from 15 to 35 per cent. and feel now that at the end of the season they will be saying the same thing about short allotments.

The medium-priced and so-called cheap cars are doing the business in the sections visited by the tourists. Except in the cities the high-priced cars were a rarity. Farmers are buying cars, and lots of them, but they are not putting all of their eggs in one basket. Following is the summary:

1	Buick	Emil Hokanson	0	0	0	0	0	0
2	Case	Jake Hanson	0	0	0	0	0	0
3	King	H. M. Hanneman	0	0	39	0	0	39

Porter's Overland Wins Watson Cup

18-Year-Old Girl Wins Woman's Cup in a Ford—Farm and Ranch Tour on the Way

Flanders Electric Will Blaze Way for A.A.A. Tour—Milwaukee Raising Money for Races

SYRACUSE, N. Y., July 24—Twenty-five cars competed in the the third annual run held by The Automobile Club of Syracuse for the B. E. Watson trophy cup, held Saturday, to Trenton Falls and return, a distance of 143 miles. The run out was made *via* Rome and the return *via* Utica.

The weather conditions were ideal. A short stay was made for dinner at the Trenton Falls Hotel and the cars checked in on the return at about 7 o'clock, the start having been made at 9 a. m. Trenton Falls is in the Adirondack foothills 20 miles north of Utica.

R. E. Porter, driving an Overland, was declared the winner, he having come nearest the secret time allowance based upon the speed regulations of the general state law and the various towns and villages traversed. Mr. Porter made the trip in 7:54:12, coming within 2 minutes of the secret time, which was 7:51:18. J. L. Youman's Mitchell car was second with 7:47:32 and C. Badgeley was third with 7:56:17. He drove a Franklin.

Miss Pearl E. Cheshire, 18 years old, won the woman's cup with a Ford, her time being 7:28:54. The trophy was offered by the club. Mrs. L. C. Whitbeck was the only other woman driver. She covered the distance in 6:53:40.

President H. W. Smith and Secretary Forman Wilkinson, of the club are in favor of substituting for the annual Watson cup run a contest of a similar nature but for a cup to be awarded by the club.

Farm and Ranch Tour Starts

DALLAS, TEX., July 22—The automobile tour of the Farm and Ranch Publishing Company, of Dallas, started from Dallas this morning and will end next Saturday night. The tour is being participated in wholly by farmers and ranchmen of Texas. Each driver of the car owns his own machine.

The entries include the following cars and owners: Buicks—W. G. Maze, of Moody; T. O. Williams, of Irving; H. L. Perkins, of Ennis; N. B. Feagans, of Ennis; G. J. Merritt, of San Marcos; C. P. McKensie, of Mexia; Albert Marrs, of Moody, and H. V. Kendrick, of Moody. Fords—C. C. Gipe, of Moody; W. R. Newton, of Hillsboro; Wm. F. Ramming, of Iowa Park; G. E. McDaniel, of Hillsboro; R. G. Roach, of Dallas. Cases—W. H. Anderson, of Kerens; T. L. Swink, of Dawson; W. C. Armstrong, of Plano. Mitchells—J. N. Colwick, of Norse; R. B. Dunn, of Bryan. Overlands—O. L. Sims, of Paint Rock; Verge Coleman, of Kerens, W. R. Garland, Annona. Hupmobiles—E. B. St. Clair, Tague; Paul G. Lundell, of Taylor; S. J. Hall, of Malakpoff; W. A. Hamilton, of Dallas, and D. B. Currie, of Kerens. E-M-Fs—J. M. Howe, of Forney, and W. Bean, of Howe. Reo—W. G. Camp, of San Gabriel. Cadillac—W. C. Kingsley, of Garland. Regal—E. C. Clark, of Plano. Maxwells—D. W. Rutherford, of Waxahachie; L. B. Blain, of Alvaroado, and Taylor McGinnis, of Terrell. Franklins—A. J. Poulter, of Waxahachie; W. B. Gregg, of Denton, and W. R. Bishop, of Carrollton. Chalmers—W. B. Mickle, of Plano. Oaklands—B. F. Wilkinson, of Ferris, and B. H. Matthews, of Mart. Hudson—J. Mantel, of Dallas. Knox—Henry Hosford, of Waxahachie. Brush—W. C. Chiristian, of Elm Mott.

Flanders Electric A.A.A. Pathfinders

The A. A. A. National Reliability Tour officials met on July 16 and awarded the pathfinding privilege to the Flanders Manufacturing Company, of Pontiac, Mich. The method of doing this most important work will be unique, in that a Flanders Electric will be utilized. The car will probably start on its trip within a week and special arrangements are being made for recharging the car along the entire route.

The greatest interest will attend the performance of the pathfinder throughout the journey from Detroit to New Orleans.

Milwaukee's Big Races Financed

MILWAUKEE, WIS., July 23—The international road racing carnival to be held at Milwaukee on September 17, 20 and 21 has been entirely financed by the business interests of the city, and a mail order seat and parking space sale of better than $15,000 has already been recorded.

There will be 75 to 80 cars on the Milwaukee course in the four events, the contests for the Grand Prix, Vanderbilt Cup, Pabst Blue Ribbon and Wisconsin Challenge trophies.

The tentative entry of three Peugeot cars, including the Boillot Peugeot which won the French Grand Prix on the Dieppe course, has been delivered to Manager Ruddle. H. E. Hewlitt, of Los Angeles, has mailed the entries of three Fiats, which will be piloted by Tetzlaff, Caleb Bragg and Bruce-Brown. It is likely that the Fiat which Bruce-Brown drove in the French classic will be brought to America, making a team of four Fiats.

Contracts were signed on Monday for the services of 1,000 members of the Wisconsin National Guard to police the course. Sheriff William Arnold, of Milwaukee county has arranged to appoint 200 deputy sheriffs and Chief of Police John T. Janssen expects to have 100 patrolmen and a dozen or more plain clothes men on duty during the three days of racing.

Why a Car Looks Dingy, and How to Prevent It

Hurried Finishing, Improper Washing, Impure Air and Insufficient Light Are Some of the Causes

Plenty of Pure Cold Water, Properly Applied, Is the Greatest Panacea for Varnish Ills

TO CARE for the automobile intelligently the owner should first have a knowledge of the causes and reasons for the things which he desires to avoid. Especially in the care of the paint and varnish, and notably the latter, it is essential to know what produces certain disastrous manifestations, what are the most efficient methods of prevention as well as an outline of possible remedies for cure.

Naturally, varnish comes in for the major share of attention. It is the beautifier and the protector of the colors, and of all the pigments going before the colors. That it cannot very well have an excess of care lavished upon it is self-evident. It costs considerable to prepare the way for it. It is expensive to apply, both in the matter of labor and material cost, and while a material of sturdy life, this may be cut off prematurely.

Loss of the intense brilliancy that is characteristic of varnish, is due to a number of causes concerning which the owner of the car should be well informed. It may, of course, be due to old age, for, like everything else, varnish grows old, and in the natural order of perishable things loses its vigor and its power to retain the freshness of youth. Loss of luster often is due to mud splashes and smears having been left to dry upon the surface. Hurried processes of painting are not infrequently responsible for the premature loss of luster—of "going dead," as it is technically termed. Porous undercoats which absorb an excess of the oil of the varnish also cause loss of luster.

As it is the natural destiny of varnish to grow old, in like manner it is the destiny of this precious material to crack and splinter, and, ultimately, to fall to pieces in the form of fine powder. Whenever varnish loses its elasticity and becomes brittle it is practically certain to chip off, When it does this the fissures and cracks run in every direction, criss-crossing each other, and showing blocks of every conceivable size and shape.

Cracks Due to Road Shocks

The automobile usually has a display of "force" cracks due to the strains of the body while on the road. Force cracks appear upon the panels of the car doors, streaking in wavy outlines across the door, starting usually near to the door handle along the edge of the door. These cracks come from slamming the door shut, causing a strain and a vibration which even the highest class varnish cannot withstand. A little more care in opening and shutting the car door will result in prolonging intact the body of varnish placed upon it. Insufficiently stiffened or "backed up" panels usually show a profusion of "force" cracks. There is scarcely any remedy for this trouble except revarnishing in case the surface has not been chopped into too deeply. If the force or other cracks have burrowed into the surface beyond choking up with a fresh supply of varnish, then the only direct and sure way is to burn off the old paint and finish and fetch the work along from the bottom up. In case the force checks appear to have been merely bitten slightly into the surface, the car should go around to the shop and have the surface rubbed lightly and revarnished.

Of course varnish sweats, just as man sweats, but the results are usually more expensive. It all depends upon conditions. The principal reason for the sweating of varnish is that of rubbing the surface with water and pumice stone and letting it stand around for some hours before varnishing. Apply varnish over color coats not thoroughly dry, and it is prone to sweat. Instruct your painter against the practice of varnishing over sweaty surfaces. About the only known remedy for this sort of trouble is to give the varnish, in due time, an easy rub over with pulverized pumice stone and water, clear up, and revarnish.

The newly varnished car if run out and left to stand under the direct rays of the hot sun is likely to deaden out by sheer intensity of heat. This form of sweating out can be cured only through the medium of a new coat of varnish applied after the sweaty coat has dried and been given a rub down with water and pumice flour. Even a high-class varnish left to stand in a garage wherein a damp, fetid atmosphere prevails, or in which are confined certain actively poisonous gases, will sweat and take on a scum fatal to good looks. This trouble should be guarded against by introducing thorough ventilation into the garage. Fresh, pure air, and plenty of soft, subdued light will prevent bad conditions in the garage.

Causes of Varnish Spotting

Spotting of varnish is an altogether too common incident in the history of varnish use. Under certain conditions, it may as well be admitted at the outset, all varnish will spot, notwithstanding the fact that some varnishes spot more easily than others. For example, a highly elastic varnish, by reason of the greater percentage of oil which it contains, will spot more quickly and with less cause than a harder drying varnish containing a smaller proportion of oil. Again, some varnishes in the early days of their life upon the surface just naturally show an extremely sensitive streak and fairly "spot on sight."

Concerning these spots let it be said that they develop through the forced extraction of the oil and some portion of the gum constituent, from the varnish. Fresh accumulations of mud, and especially the mud and dust of city streets, and the mud of lime districts, act quickly and powerfully upon varnish recently applied to the surface. Therefore this injunction: Wash the car as soon as it is brought in from the muddy or dusty highway. Thereby save the gloss of the varnish and give it renewed strength to stand the stress of service.

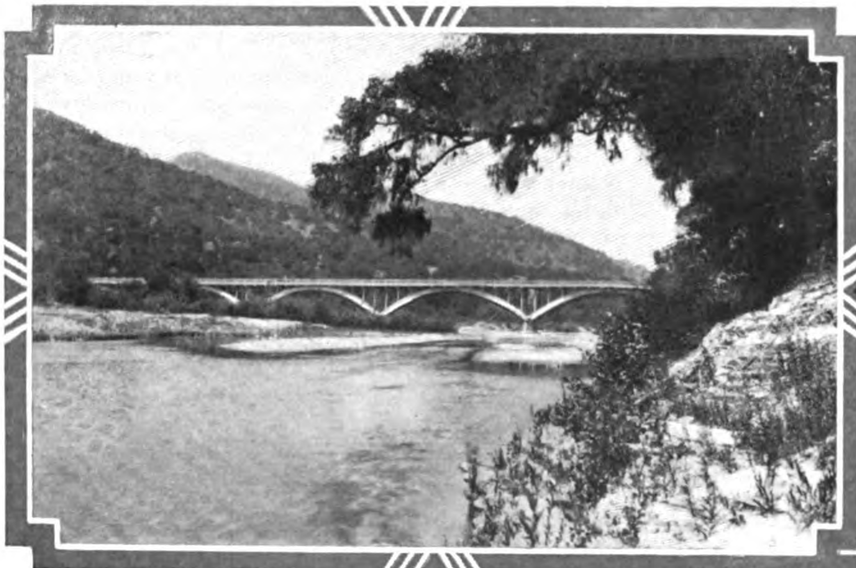
Other causes of varnish spotting which a car owner should be aware of consist of soapy or dirty water, and a prolific brood of gases, these latter casting a blight over the face of the varnish well-nigh beyond effacement. Spotting from coal or other gases develops in the shape of round, lifeless spots overcast with a blur of greasiness, and they transform the car into a patchwork picture. The only remedy for this sort of deviltry is to rub the surface off with water and pumice flour and flow on a new coat of varnish. Soapy or dirty water spots, if caught in time, may be washed off slick and clean with clear water.

The prevention of varnish spotting may be summed up in this way: Wash the car often with clean cold water, which treatment not only hardens the varnish, and increases its brilliancy, but prevents it from being acted upon by the manifold accumulations.

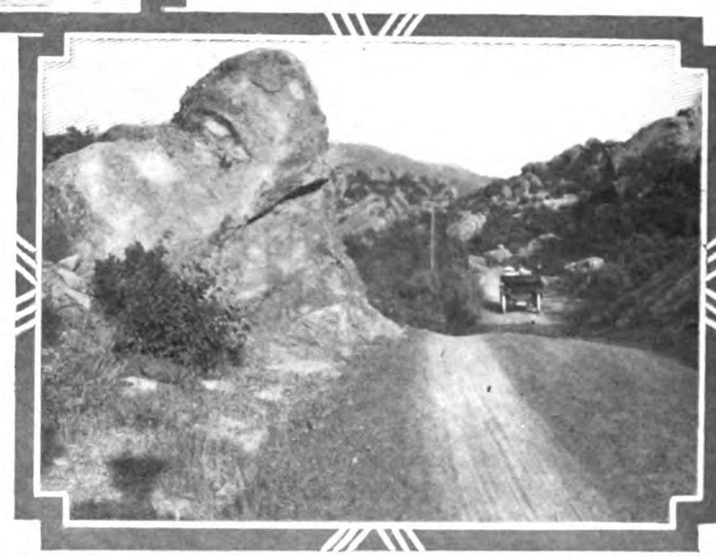
Another phase of varnish care-taking with which the car owner should familiarize himself is greening. This is a discoloration of varnish, or, rather, a discoloration of the color field, through which the varnish takes on or appears to take on an objectionable greenish cast. This trouble may be developed by applying successive coats of clear rubbing varnish over a black or very dark colored field of pigment, but under the prevailing practice it is not likely to.

The common cause of the greening of newly-finished surfaces is the storage of the car in dark garages, in which little or practically no natural light is allowed to enter. To prevent this discoloration give the garage or repository plenty of good light.

Varnished surfaces which, when exposed to a damp atmosphere or to certain gases, take on a metallic-like film, cloudy or smoky, are said, in technical parlance, to have bloomed. It is an objectionable manifestation. Washing the surface with clean, cold water will often restore the original brilliancy of the varnish. This remedy failing, rub down the surface and revarnish.



New San Lucas bridge, looking down stream



Party of motorists inspecting the new bridge

Crossing the divide on the San Marcos Pass

Bridge for Automobilists

Takes the Place of a Ford Over the Santa Ynez River, Where Many Lives Have Been Lost

Forms Portion of the Coast Route Over the Wildly Picturesque San Marcos Pass

SANTA BARBARA, CAL., July 12—To the automobile alone is due the new $40,000 concrete bridge, which was formally opened July 4, by a gathering which included motorists from the most distant points of the country, many of them coming 50 and 75 miles to attend the celebration.

Located virtually in the wilderness, several miles from any settlement or railroad, the opening of the bridge was considered of such importance that the event was attended by 2,000 persons. Being in the Santa Ynez valley territory, the ranchers of that section arranged the barbecue, and five beeves and other gastronomic delights were consumed during the day. In other words, it was a ton of beef that was required for a festival that savored much of early-day Spanish hospitality.

Bridge-Opening a Festivity

Alonzo Crabb, a prominent citizen of the valley, was the moving spirit of the celebration, and he secured the donations of beef and other victuals, so that everything was free to all who attended. Mr. Crabb curtly explained how he secured the beef: "Supervisor Al Conover and Ed Donahue each contributed a beef, and I stole the other three."

The new bridge is located 35 miles from Santa Barbara, and a quarter of a mile down the Santa Ynez river from the old ford. This is the only place where it was necessary to ford the stream on the way south to Santa Barbara, and thousands of automobilists in various parts of the country who have toured California, and gone down the Coast by way of the San Marcos pass, will recognize the spot. It is about 5 miles east of the old Santa Ynez mission, near which place one chooses either the San Marcos or Gaviota pass for proceeding southward.

But the San Marcos was the original stage road, prior to the days of railroads in this country. During the rainy season the Santa Ynez river, which has its course in a wild and rugged mountain section, all of which is included in the Santa Barbara National Forest, becomes a raging torrent. In summer it is a mere stream and in most places having the proportions of a creek. But the winter rains rapidly swell it, and floodtides sweep down, and many persons have been caught at the ford and lost their lives. This is the only dangerous part of the road from the old town of Santa Ynez to Santa Barbara, although careful driving is required to make the San Marcos pass at all times of the year. The pass will never be a race course.

Conditions at the ford were at times so aggravating that the board of supervisors more than a year ago instructed Frank F. Flournoy, the county surveyor, to prepare the plans. The work was started last fall and finished in time for the grand opening. The bridge is of five spans and has a total length of 700 feet.

Santa Barbara Improving Roads

Had the automobile never come there would be no bridge at the San Lucas crossing. Santa Barbara county is at present in the midst of good roads activity, brought on, not so much by the growth of the automobile class here, but from a realization that it must provide for a rapidly increasing tourist traffic. Because of its roads this county was severely criticised in the past, and a few years ago a spirit of improvement took possession of the people and more than $500,000 has been expended on permanent roads in the county, and particularly on those leading out of the city of Santa Barbara. This will surely compare favorably with other communities of the country when it is known that the entire population of the county is only about 20,000. But the county is a prosperous one. Pauperism is virtually unknown except in rare cases, and they can largely be attributed to the infirmities of age.

Of all portions along the Coast highway from San Francisco to San Diego the tourists have marveled most over the San Marcos pass. The total length of the pass is about 15 miles, and it starts through the mountains 10 miles west of this city, then continues along tortuously, the greater part of the road being unimproved as far as paving goes. The pass has its history. In 1847, when word was received in Santa Barbara that John C. Fremont was on his way south to capture the city, a force was sent out to meet him. The Mexicans placed themselves in the rocks over a narrow cut in the Gaviota pass, prepared to hurl rocks down on the American soldiers when they passed beneath. But Fremont came by the San Marcos pass, entered Santa Barbara quietly and the city was taken without any bloodshed. Since then it has been an American possession.

Scenic Beauty of San Marcos

Starting at sea level, the pass mounts to a height of 2200 feet. Some of the views are sublime. One has far glimpses of other ranges than the one through which one is passing, at times with deep-cut canyons that probably never have been thoroughly explored by man. Most of the land is of little value, but seems to have been hurled together by the Creator solely for scenic purposes. And scenically much of this will in the future be presented by moving pictures the world over. It was only a couple of days after the opening of the bridge that the players of a film manufacturing company moved on Santa Barbara as quietly as did Fremont, the pathfinder; but unlike him, however, they have decided to make this their permanent home, and in the near future scenery of the range through which the San Marcos passes will serve for its stories. The film people consider they have discovered a scenic nugget, and are now wondering why it lay here untouched so long.

It can be stated that while the bridge just completed is the finest of its kind between San Francisco and Los Angeles, it will soon have its equal. In THE AUTOMOBILE recently reference was made to the Rincon causeways. An important part of the sea-level road improvement south of Santa Barbara will be a concrete bridge over the Ventura river, which will cost $50,000. It will be about 900 feet long and the money is being realized by a special tax levy in Ventura county. Its design will be similar to that at San Lucas.

At the barbecue referred to there was an interesting character present in John Waugh, who started to drive stage over the San Marcos in 1860 and was on that job for 40 years. He had been engaged in similar work in various parts of the state, and when he came here had three notches in his revolver, representing the demise of as many robbers who at various times had tried to hold up his stage. He stated that when he first came here the only bridge between Santa Barbara and Soledad, 150 miles apart, was an old corduroy span over Arroyo Burro, a few miles west of this city. The stage coach went into disuse about the time the first automobile was seen in these parts. Waugh is now 70 years old and without a job. But, then, he is not in the pauper class. He delights to talk of the old stage coach days, and on the day the bridge was opened he was in his element.

Pennsylvania After Toll Turnpikes

HARRISBURG, PA., July 20—State Highway Commissioner Bigelow has announced that he would inaugurate the first of the proceedings by the state to obtain roads which are included in main highway routes, but are owned by turnpike companies. The first action will be brought to condemn the toll road between Chambersburg and the Bedford county line, which crosses portions of Franklin and Fulton counties. Later on proceedings will be undertaken to condemn turnpikes in the vicinity of Philadelphia and other cities, where such roads are on main routes. The actions will be in charge of Attorney-General Bell. It is the idea to take over the turnpikes as needed to improve main highways and energetic action is expected.

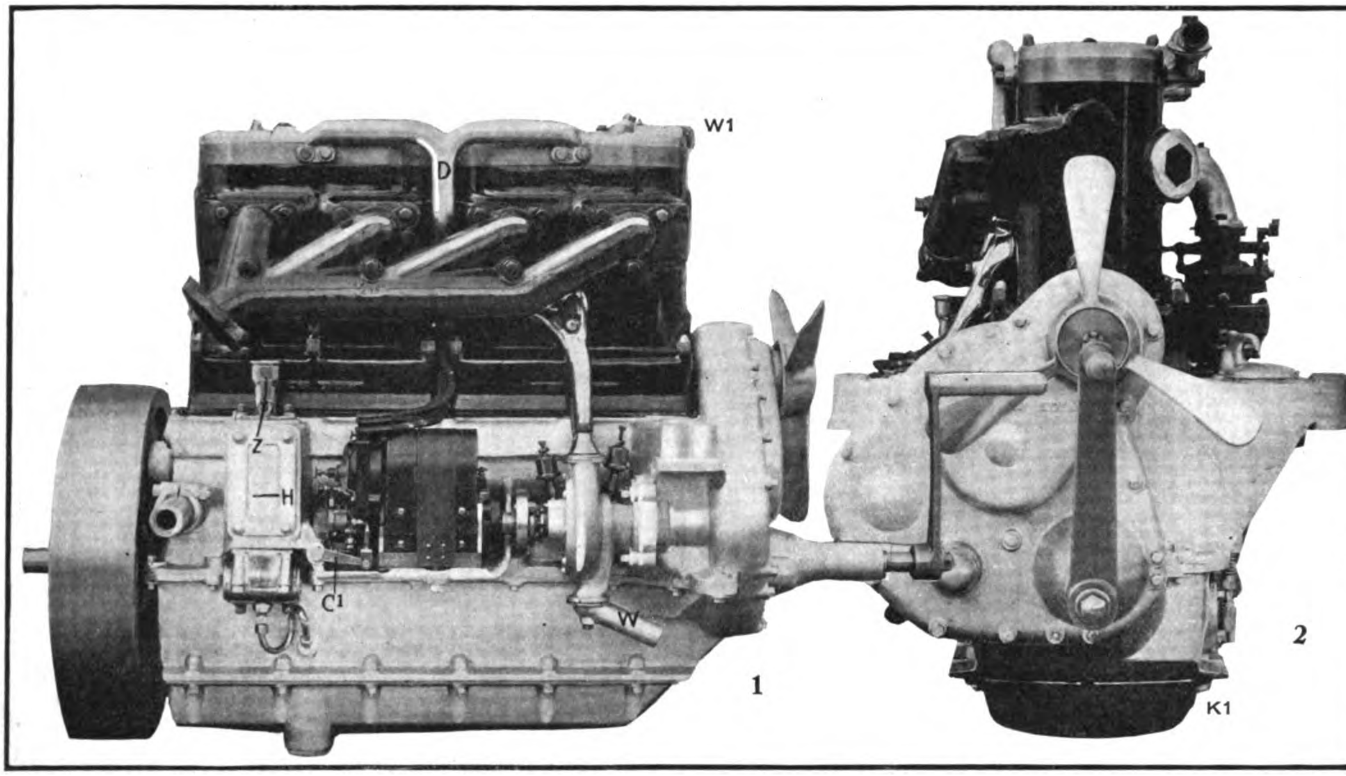

Figs. 1 and 2—Exhaust side and front view of Atlas-Knight sleeve-valve motor

1913 Atlas Motor

Many Improvements Incorporated in the Latest Model of Knight Double-Sleeve Engine

Pressure-Feed Lubrication, Longer Sleeve Travel and New Design of Cylinder Castings Are Among the Features

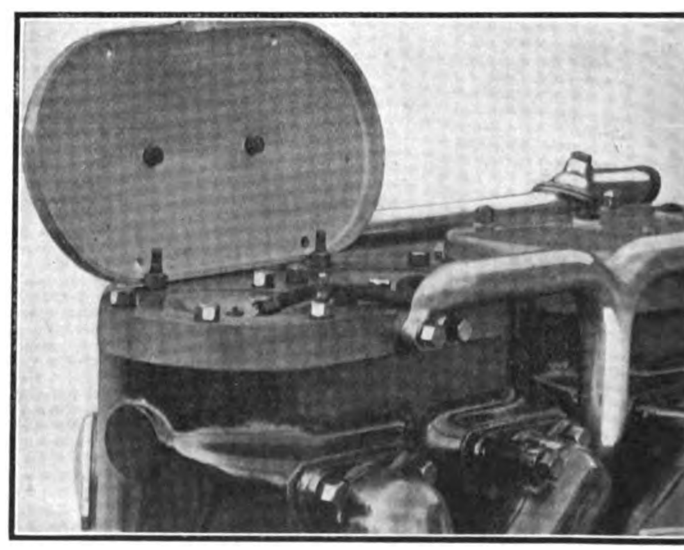

Fig. 3—Spark-plug cover plates on Atlas motor

THE Knight double-sleeve motor has entered on a new phase of activity in America by the recent announcement of the Atlas Engine Works, Indianapolis, Ind., that it has completed development of this motor and it is now in the manufacturing stage. This concern over a year ago signed with Knight & Kilbourne securing the sole right to build these motors in America for sale to automobile concerns. Since that time its engineers have been busied on working over many parts of the motor so that in its final presentation to the American public it possesses several features not heretofore adopted by the standard Knight types in Europe and as used on several of the Knight types built in America. In this connection it might be stated that the trough oiling system has been eliminated and a pressure feed non-splash system installed; the eccentric shaft driving the sleeves has been mounted on the right side, leaving the left side of the motor practically clear excepting for the carbureter and adapting it for cars with the steering pillar mounted on the left side, at the same time giving room for the column on the right if desired; the sleeve travel is made longer than in any other makes of this motor and since its introduction this longer travel has been taken up by other Knight licensees. The cylinder castings are entirely altered so far as external appearance is concerned, and not a few other details incorporated.

For the present the Atlas has but one model, a four-cylinder one, with 4.5-inch bore and 5.5-inch stroke which has a formula rating of 32.4 horsepower, but when tested on the block at the speed of 1,090 revolutions it generates 47 horsepower, or over 44 per cent. above the standard rating. At 1,875 crankshaft revolutions the block test is 69.5 horsepower and at 1,900 the test shows 70.5 horsepower—a piston speed of 1,740 feet per minute.

In designing its initial motor the company has set a high mark in compactness of design, in symmetry of lines and in accessibility of parts, modern practices having been followed out wherever possible. There has not been any aim at the radical but rather the accepting of all that has stood the test of years in motor building. The aim has been to produce the best, so far as design, materials and workmanship go. Fig. 6 shows the intake side with the manifolds A cast integrally with each twin casting, thus reducing the intake to a small three-arm connection which unites by hexagon nuts with the manifolds and by flange with the carbureter. This side contains little else than the oil filler cap G, which is so interconnected with an overflow cock G1 that when the filler cap is off the overflow is opened, thereby furnishing a very ready test as to when the oil is filled to the desired level, and a float glass G2. The transverse control arm C is made a corporate part of the motor and connects at the opposite side through the arm C1, Fig. 1, with the magneto breaker box arm.

The exhaust side is neatly arranged, the centrifugal water-pump being mounted immediately back of the forward motor arm, with its shaft continued to drive the magneto. Back of the magneto are the two pumps, air pump Z, for pressure on the gasoline, and oil pump carried in a detachable housing H. The ejector type of exhaust manifold is carried well up and conceals beneath it the water manifold. A neat job is made of the wiring by the conduit D, which effect is accentuated by using aluminum cover plates, one covering the entire head of each twin casting and concealing the spark-plugs, thereby proofing the ignition system against water. Fig. 3 shows one of these plates removed and having in it two grounding plugs, one above each spark-plug. Finger pressure on either plug brings it onto its respective spark plug and so short circuits it, furnishing an easy way of testing for fouled or injured plugs without having to remove the cover plates.

All Manifolds Simplified

Water piping has been minimized, water entering by an intake W under the front motor arm and discharging through a short pipe which connects with the cylinder heads. In this, as in all other Knight motors, the head is a separate casting, and, like the cylinder, is water jacketed, calling for transfer passages from the cylinder jacket spaces to the head jacket spaces.

The crankcase is a three-part casting, the upper portion carrying the five bearings of the shaft as well as magneto, carbureter, oil pump, air pump, oil filler, etc.; the lower part is an oil reservoir, and the middle portion is merely a uniting section furnishing adequate room for the lower ends of the connecting rods. The novelty of the case consists in entirely insulating the bottom portion from the middle portion by an air space, this space extending from end to end and insuring cooler oil and so better viscosity and better lubricating qualities. The middle portion is divided in halves by a central transverse bridge and in each half the floor slopes to the center, where it forms a drain into the oil reservoir. The oiling system is entirely pressure feed to every bearing, and to all the pistons and sleeves.

Fig. 7, an end section, shows many of the important features. The twin-cylinder castings have an enlarged base part K, made to accommodate the enlarged lower ends of the sleeves and the sleeve connecting rods, and by this enlargement being on the cylinder instead of on the crankcase it makes the lower part

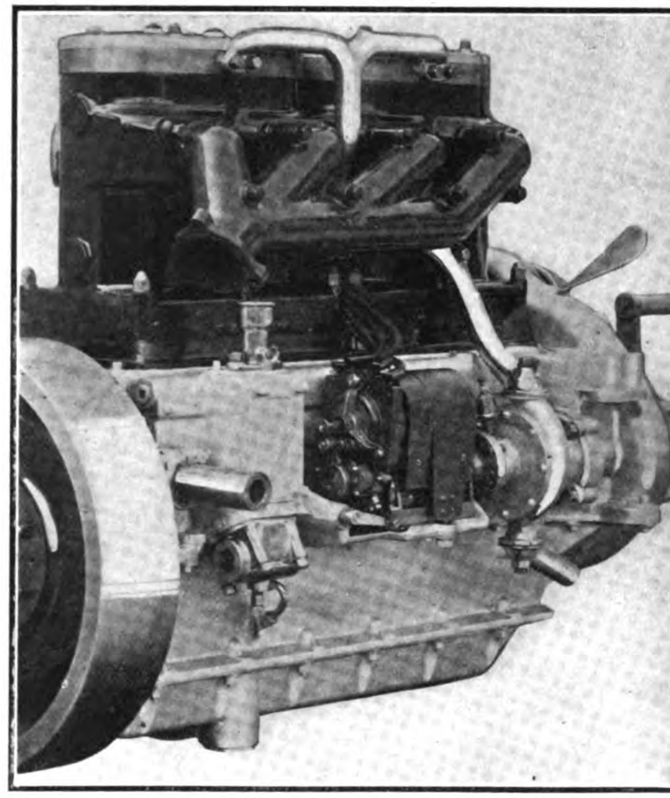

Fig. 4—Accessibility of motor parts in Atlas engine

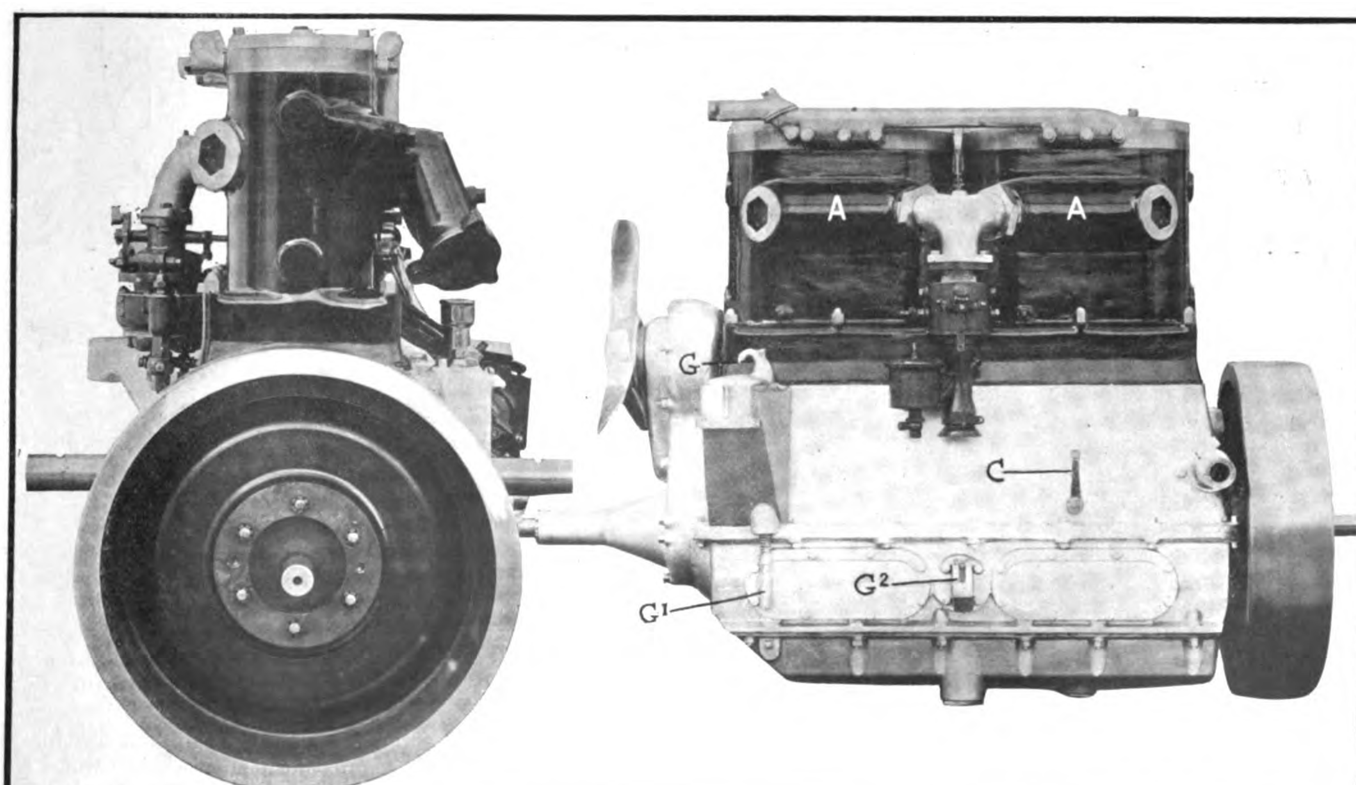

Figs. 5 and 6—Rear end and intake side of Atlas sleeve-valve motor

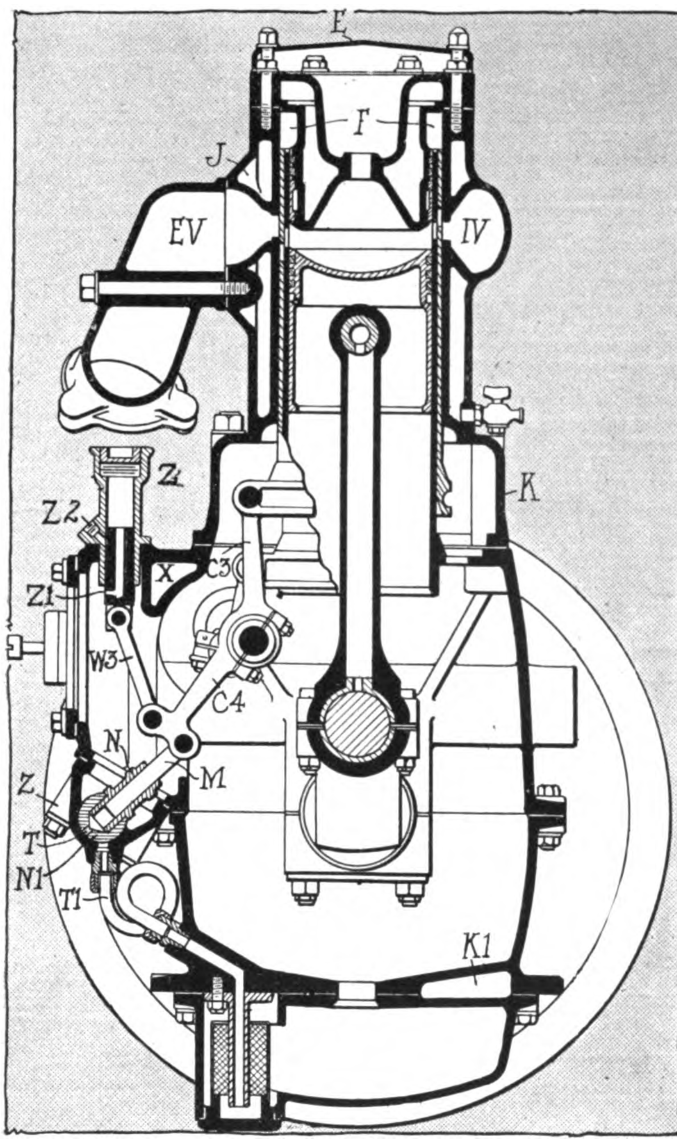

Fig. 7—End section of Atlas-Knight motor

of the sleeve and the top bearings of the sleeve connecting rods entirely accessible when the casting is removed. The water jacketing J completely surrounds the exhaust port EV at top and bottom, and is extended to the end of the flange. On the opposite side the intake manifold, cast integrally with the cylinders, is also water jacketed. This tends to prevent condensation and improves carburetion.

The new pressure-feed oiling system centers around a single plunger pump driven from the eccentric shaft and forcing oil to the five eccentric shaft bearings, the five crankshaft bearings, the eight lower bearings of sleeve connecting rods, the eight upper bearings of these rods and the upper and lower bearings of the large connecting rods which work the pistons. In addition this pump oils the silent chain which drives the eccentric shaft, the magneto, water pump and fan. The use of hollow connecting rods aids in the work. The oil pump is a plunger M working in a cylinder N. The plunger is driven through the arm C4, which is a part of the sleeve connecting rod C3. This arm also drives the air pump Z. In operation the oil pump cylinder N, which is rigid with a short horizontal cylinder N1, is oscillated by the large arc through which the end of the arm C4 works. The oil port T registers with the intake pipe T1 from the reservoir on the up or suction stroke and on the down or pumping stroke the port T has been oscillated out of register and into register with a pipe leading to the tubular passage X in the crankcase. From this passage branches lead to each of the five eccentric shaft bearings. The oil flows through these bearings and through the drilled throws of the eccentric shaft to the lower sleeve connecting rod bearings. These rods are hollow and fill with oil and so feed their upper bearings or where they attach to the sleeves. From the eccentric shaft bearings oil passes through drilled openings to the main bearings of the crankshaft and through the drilled shaft to the lower main connecting rod bearings, and up the hollow rods to the wrist pin or piston pin bearings. From these the oil flows through the hollow wrist pin against the sleeve walls and works down into the crankcase whence it is filtered back to the reservoir, ready for re-circulation.

The air pump for air pressure on the gasoline is a two-cycle one, the plunger having but a single port Z1, which leads from the side near the base up through its center to the top. Air enters and leaves by this port or opening. When the plunger

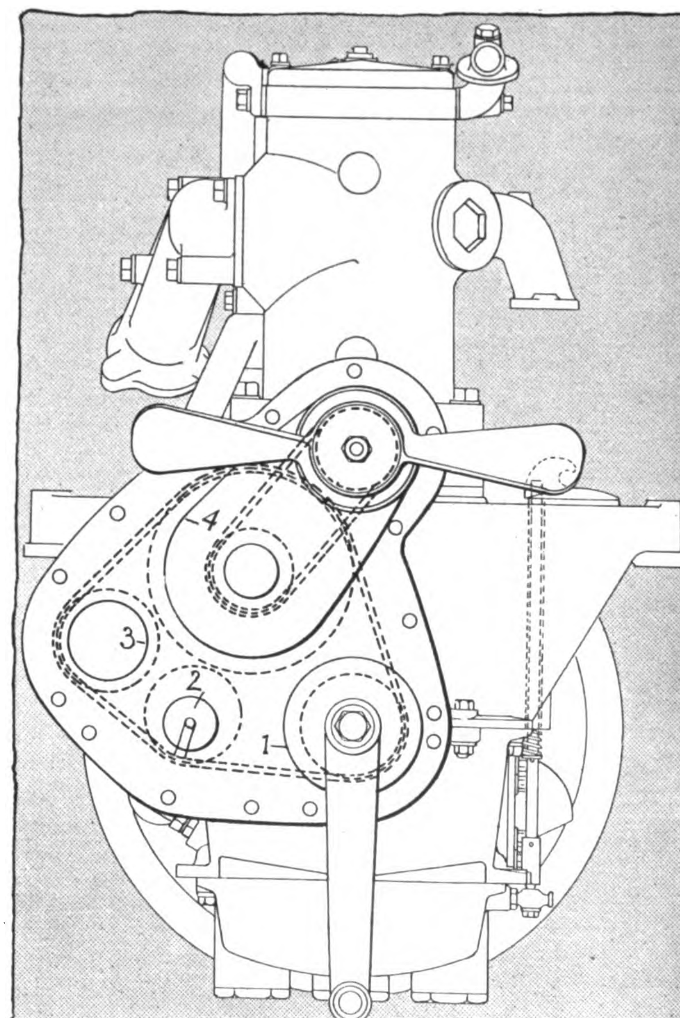

Fig. 8—Silent-chain drive for Atlas motor

is down air rushes into the port to fill the partial vacuum created above the plunger. On the up stroke the port Z1 is closed by the cylinder wall and remains closed until it registers with the exit port Z2, the air in the meantime being compressed above the piston and as soon as released passes to the gasoline tank. With this pump ball or other types of check valves are not needed. The pump plunger operates through the arm W3 hinged to the same crosshead that works the oil pump.

Both the oil and air pumps are unusually accessible. The oil pump cylinder is carried in the housing H held to the top part of the crankcase by four studs and connected with the oil reservoir by a pipe T1. The pump can be detached, leaving the plunger M connected with its crosshead, the work calling for but a very few minutes. An improvement in this motor which aids in lubricating is the use of an annular expansion chamber F at the top of the sleeves, which collects oil working up past the sleeves and also partially fills with air which when compressed forces the oil downward between the sleeves, insuring the presence of a film of oil at all times.

The use of two silent chains to drive the various motor parts is shown in Fig. 8, in which the main chain passes over four wheels or pulleys No. 1 on the crankshaft, No. 2 an idler, No. 3 the pump and magneto and No. 4 on the eccentric shaft. This chain is 1.5-inch wide and of .5-inch pitch. The four wheels over which it runs have teeth as follows: No. 1 crankshaft, twenty-three; No. 2, idler, twenty-two; No. 3, pump, twenty-three, and No. 4, eccentric, forty-six. The second chain driving the fan from the eccentric shaft is narrower, but of the same pitch and drives over seventeen-tooth pulleys. In oiling the main chain the shaft of the idler pulley No. 2 is drilled and the pulley also drilled, so that when these drillings register as illustrated the entire pump pressure forces oil into the inside of the chain and it works through the chain to its entire surface, assisted by centrifugal force. By mounting the idler eccentrically on its shaft the chain tension can be corrected at will.

Friction-Driven, Two-Blade Fan

Fig 9 shows the two-blade aeroplane type of propeller fan. The fan is not rigidly connected to its shaft, but friction driven through a combination metal and fibre disk clutch with spring engagement. A steel disk L, Fig. 9, is keyed to the shaft and between it and the fan hub L1 is a fiber disk L2. The coil spring forces the hub and fiber disk against the steel disk with sufficient pressure to drive the fan, but with delicacy to allow slipping when suddenly starting and stopping. This illustration shows the general use of hollow connecting rods for the piston and both sleeves. Fig. 10 shows one rod C, a chrome nickel forging of round section and with a drilled hole from end to end 7/8 inch in diameter, leaving a metal wall 1/8 inch thick. The tubular part is of uniform diameter, excepting at a point one-third, or thereabouts, from the lower end, where it is slightly increased, this being the point of maximum strain. The tubular portion expands with a generous fillet into the large lower end, which takes a cap secured by four chrome nickel steel bolts. The use of a tubular section has reduced the weight of a connecting rod to 3 pounds 15 ounces without the bushings. The rod is 12.5 inches center to center, which is 1.5 inch more than double the piston travel.

Fig. 10 also shows the use of tubular rods of the same design for both sets of sleeves. The external appearance of the entire set of rods is shown in Fig. 10, a photographic reproduction of the regular stock product.

The Atlas sleeves are of their own manufacture the same as all of the other castings. Each sleeve is 5/32 inch thick. It has been customary with the foreign Knight licensees to make the outer sleeve thinner than the inner, the latter having to take care of the piston side thrust. This practice has been changed by the Atlas by making both alike, the claim being that the outer sleeve moves against the piston on its working strokes and calls for additional strength. Each sleeve has its intake slot V at the right top and the exhaust slot EV opposite. The exhaust slots measure 4 9/16 inches circumferentially and are 11/16 high. They give a total opening equal to a rectangle 3 31/32 inches by 5/8 inch, with a total area of 2.47 square inches. The intake slots measure 4 9/16 inches circumferentially and 3/16, respectively 15/32 inches high. They give a total opening of 1.98 square inches. The sleeve reciprocation is such that a quick opening and closing are obtained. The intake is opened by the inner sleeve practically standing still and the outer sleeve

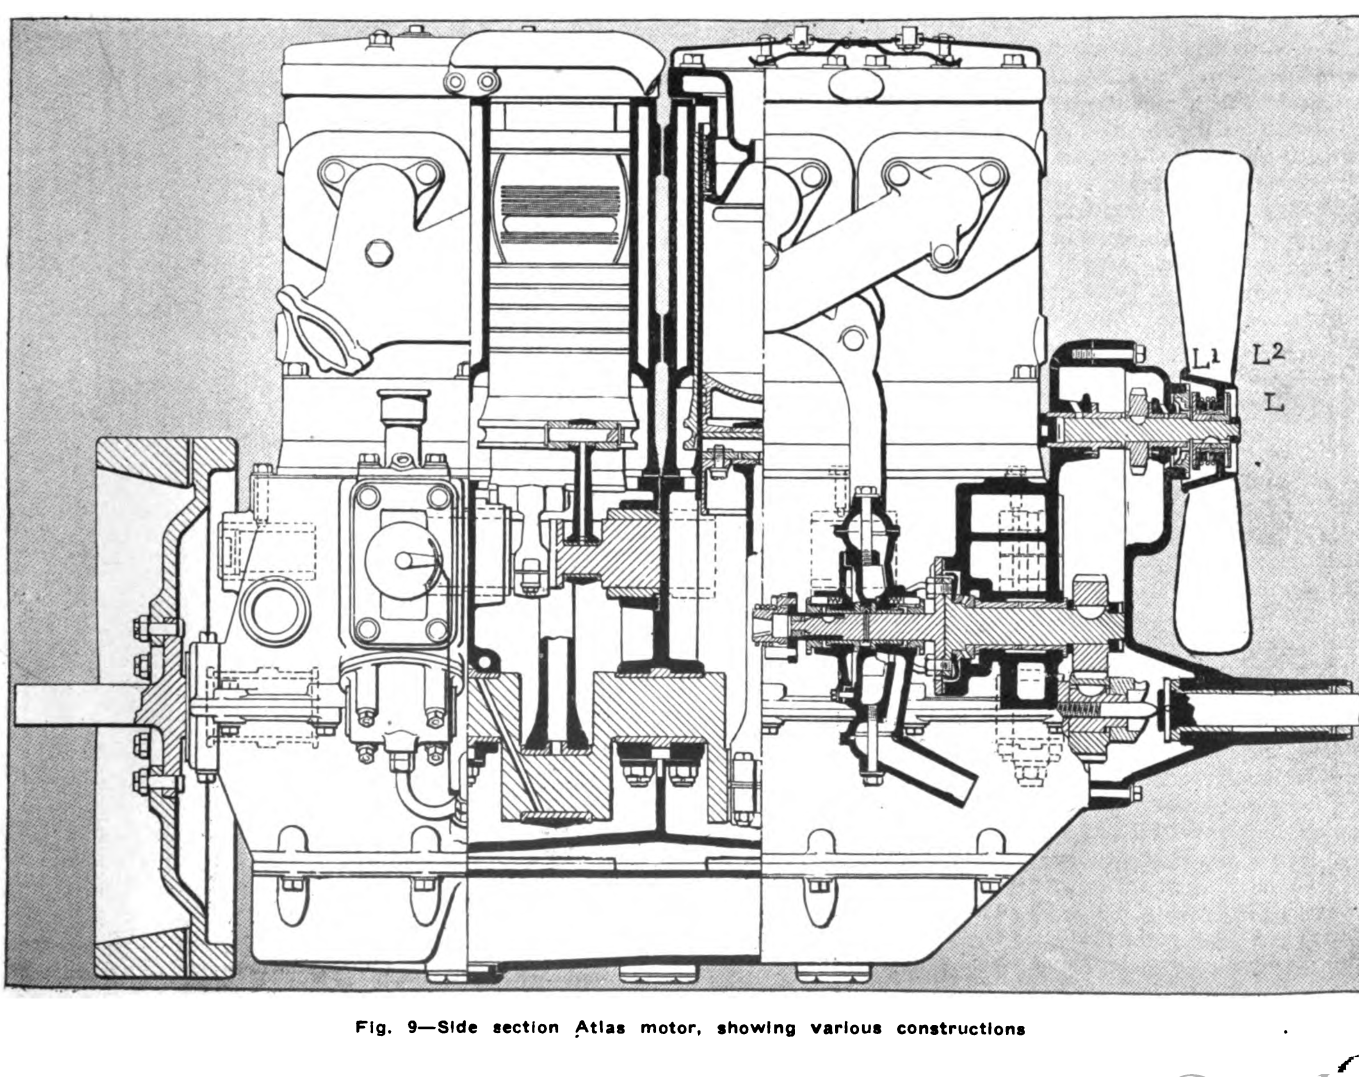

Fig. 9—Side section Atlas motor, showing various constructions

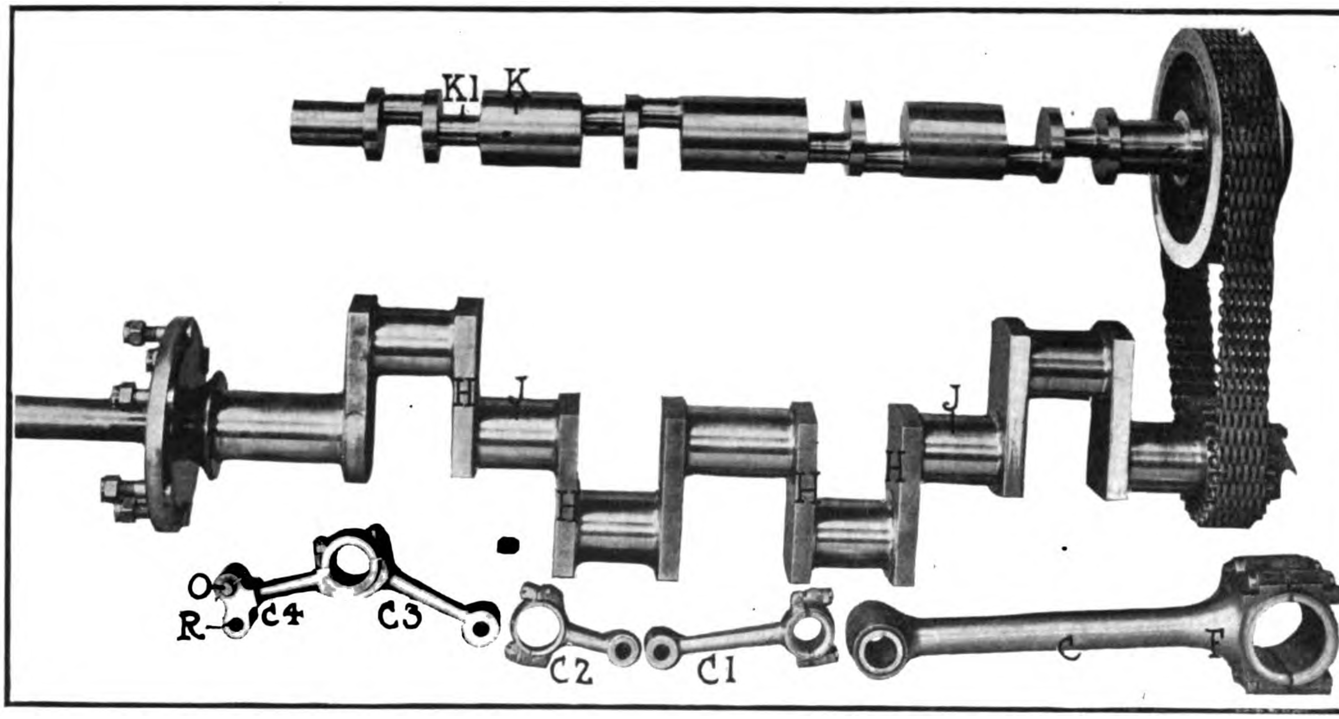

Fig. 10—Hollow piston and sleeve connecting-rods on the new Atlas motor

moving down into register, so that while the valve remains open for 205 degrees of the cycle only 105 degrees of these are required for the intake slot to open, and it remains at the point of maximum opening for 14 degrees and requires 86 degrees for closing. With the exhaust valve the port remains open for 245 degrees on the cycle and reaches its maximum opening in 120 degrees, remains at its maximum opening for 10 degrees and requires 115 degrees in closing.

A longer travel is used than on previous Knight types, namely, 1.25 inch, as compared with 1 inch on Daimler motors and 1⅛ inch on Stearns, Stoddard and others. Using longer travel gives a greater flexibility in timing and valve opening and closing. It also aids in sealing, that is, guarding against the loss of compression through the ports on compression and firing strokes.

In the Knight motor valve timing is done by the amount of lead the inner sleeve is given over the outer one. In the Atlas this lead is 65 degrees. This gives the intake opening at 15 degrees after top dead center and closing 40 degrees after bottom dead center. The exhaust port opens 60 degrees before bottom dead center and closes 5 degrees after top dead center.

Longer Sleeve Travel

With sleeve travel of 1.25 inch there is sleeve speed in feet per minute of 208 at 1,000 crankshaft revolutions and at 1,900 crankshaft revolutions the speed is but 395 feet per minute, a speed which makes lubrication a particularly easy problem.

The sleeves are gray iron castings, a special grade of metal being used which takes a drawing test of 32,000 to 36,000 pounds to the square inch. In manufacture the sleeves are given internal and external cuts at the same time—two of each, a roughing one first and the finishing one afterwards. This done, they are ground on the inside and also on the outside. When ground internally they are held in a water-cooled holder and when ground externally are held in an expanding arbor which extends from end to end and prevents sleeve distortion. The usual circumferential oil grooves are used, with numerous oil holes. The clearance between the piston and the inner sleeve is .004 to .005 inch; between the inner and outer sleeves .002 inch, and between the outer sleeve and the cylinder wall is .002 inch. In tests the motors have been run on the block with a clearance of but .0005 inch between sleeves without any symptoms of seizing, so that the clearance of .002 inch, or four times that amount, is ample.

Pistons, Fig. 11, are gray iron castings carrying three compression rings at the top and well above the wristpin bosses. Each ring is ground on its upper and under faces, but finished by turning on its outer face. A diagonal split is used. Below the three rings is a deep wide oil groove almost as large as those

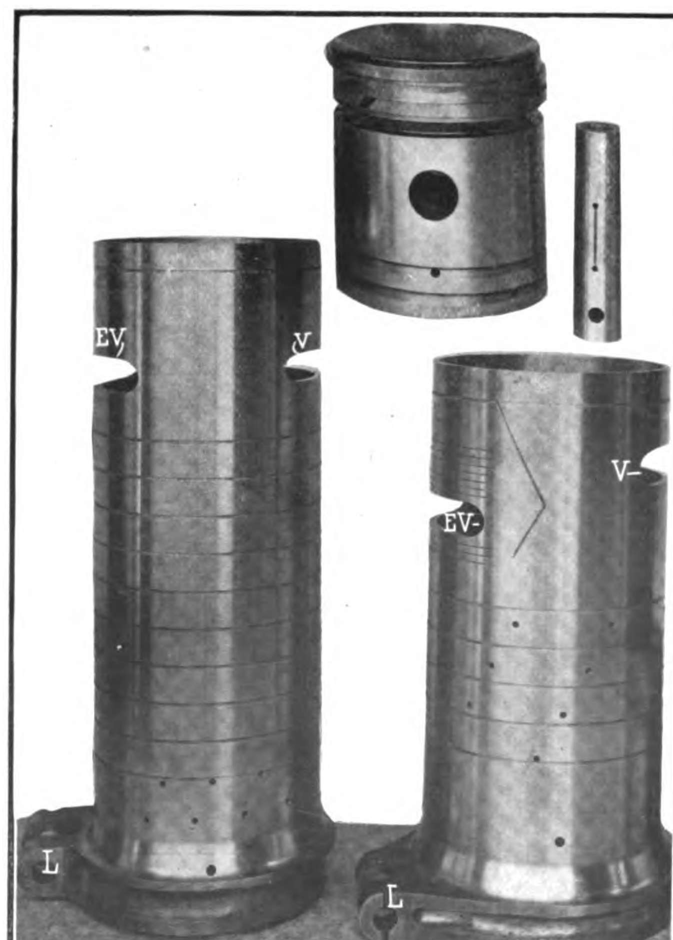

Fig. 11—Atlas sleeves, piston and wristpin

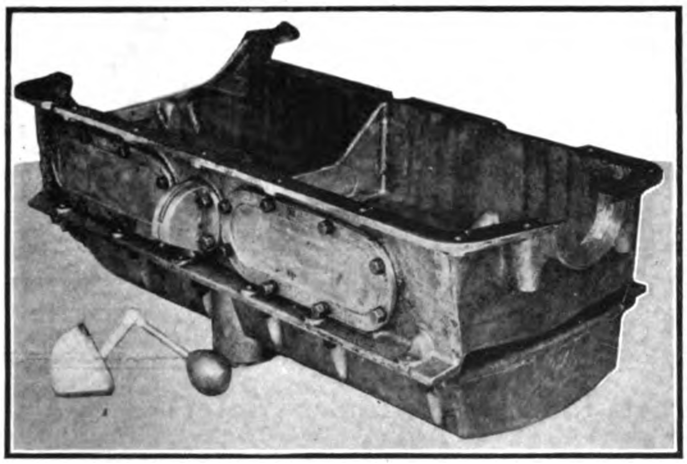

Fig. 12—Air-insulated oil reservoir

grooves taking the rings. In this groove are oil holes leading through the piston wall, their service being to drain the surplus oil between the piston and inner sleeve with low throttle and preventing oil being sucked up past the piston and causing smoking. At the base of the piston skirt are two other oil grooves with holes leading through the piston walls. Each piston head is slightly concaved.

Stout Crankcase Construction

Using a five-bearing crankshaft is conventional with four-cylinder Knight models. Fig. 12 shows the Atlas case with a solid integral web extending from side to side of the case for each bearing. Each web carries a crankshaft bearing and also an eccentric shaft bearing, and is webbed diagonally to take the strain, the diagonal web being in line with the strain on the down stroke and also on the up stroke. Four studs, chrome nickel steel, anchor the bearing caps at the flywheel end for the long center bearing and two studs for each of the other three. The crankshaft, a chrome nickel steel forging, has a bearing diameter of 2.5 inches and a total bearing length of 15.25 inches, divided as follows: 4.5 inches at the flywheel, 3.25 inches in the center bearing, and 2.5 for the front and the middle bearing in each twin cylinder casting. The eccentric shaft has five bearings.

The rigid crankcase has called for a more or less flexible four-point support on the main frame, accomplished as illustrated in Fig. 13. At the forward end are two rigid crankshaft arms each having two vertical stud holes which take bolts to anchor to the bracket S carried in the frame side members. This support permits of a certain frame twisting without transferring it to the motor base. At the rear end the support is by a transverse tube clamped at each end in a split stub cylinder S1, in turn held to the frame by a pair of horizontal bolts passing through a wood block within the frame channel. This illustration gives the various motor dimensions as needed for putting in a frame.

Among the New Books

PRACTICAL APPLIED ELECTRICITY, by David Penn Morton, B. S., E. E., Associate Professor of Electrical Engineering at Armour Institute of Technology and member of several electrical societies. Published by the Reilly & Britton Company, Chicago. 438 pages, 4 by 7 inches, with 323 figures and diagrammatic illustrations. Flexible cloth binding, $1.50.

Although the work is not in itself a text book, it could well be used as such for those who are somewhat rusty in their electrical knowledge and who wish to brush up a little on uncertain points. It could be very well used as a handbook by those who are occasonally confronted by electrical problems although who are not regular electricians. As a school text book it would not be valuable unless aided by other works on the same subject, as in many instances the descriptions are not sufficiently elementary for a beginner. A valuable feature of the work is the use of numerous examples which tend to make the subject matter more firmly fixed in the minds of the student.

RUBBER HAND STAMPS AND THE MANIPULATION OF INDIA RUBBER, by T. O'Conor Sloane, A. M., E. M., Ph. D., author of The Arithmetic of Electricity, Electricity Simplified, Standard Electrical Dictionary, etc. Published by the Norman W. Henley Publishing Company, New York.

Every one who drives an automobile is surely interested in the qualities and working methods in use with rubber. The book is largely taken up with the manufacture of rubber stamps and other similar small articles, but the method of handling it after it leaves the tree is the same as that which is used in the manufacture of tires and other articles of everyday use to the automobilist. The progress of the rubber from the time it leaves the tree as a sap until it becomes the finished article is followed step by step. Vulcanizing is explained and the properties of vulcanized rubber are also taken up. In connection with the chapter on rubber tires the methods of chemical or cold vulcanizing are discussed.

Wants Horse Vehicles to Carry Lights; Discussion on Kerosene Carbureters; State Requirements of Tourists; Spark-Plug Insulation Cracks; Further Argument on Uncooled Motor; Types of Crankshaft for Four-Cylinder Motors

Protests Against Light Law

EDITOR THE AUTOMOBILE:—Is there any law which compels horse-drawn vehicles to show two white lights with red to rear at night? With conditions as they now exist the automobilist must look out for himself at night and the other fellow as well and still get into trouble? Isn't this idea of making the other fellow carry lights a good one?

I am also sending a photograph of a bad road (Fig. 1). The road is very much traveled as it leads to a creamery, store and railroad station. I have a Buick car and when I go out anywhere I must go over this road, as I live alongside of it. Two state roads are being built to the north and south of it so that by fall it will connect them. As for automobiles traveling over it, there are about fifteen of them in this vicinity and we have been asking the supervisor to repair it, but with no results.

Birdell, Pa. J. NORWIN HATFIELD.

Best Route to Honesdale, Pa.

Editor THE AUTOMOBILE:—Please tell me through THE AUTOMOBILE the best route from Bridgeport, Conn., to Honesdale, Pa., by way of Port Jervis and Newburgh, N. Y. Also please give me the route from Honesdale to Philadelphia. J. H. C.

Bridgeport, Conn.

—This is a very good tour as the roads are fairly good for the whole length of the route. Go out Fairfield avenue from Bridgeport, turn into Clinton avenue, then Brooklawn avenue and into Plattsville. The route from there on is clear, following the lines of main travel through Easton, Redding Ridge, Bethel and thence into Danbury. Go out West street straight on past Mill Plain Post Office and follow main road to Brewster, passing through Tilly Foster Mines and reaching Carmel, going along Lake Glenida through Cole's Mills, Mead's Corners, Stormville and along the line of main travel to Clove. Turn left at Clove to Hopewell junction, Fishkill Village and Fishkill Landing.

Cross the Hudson by ferry here to Newburgh on what may be taken as the second lap of the journey. This part is characterized by comparatively rough roads but beautiful scenery. Go out West on Broadway through Coldenham and into Montgomery. Follow the main road to Goshen. Go on through Denton, Slate Hill, South Centerville through Pike street and into Port Jervis. From Port Jervis the roads are rather doubtful and the best method is to proceed by local direction through Hawley and thence to Honesville.

To get to Philadelphia, run back to Port Jervis and then to Matamoras, Pa. Go by way of Broad street to Milford and through Dingman's to Bushkill and thence on to the Delaware Water Gap. From the gap there is a trunk line route which will take you to Portland if you follow the river. Then go through Centerville, Richmond, Three Churches and into Easton. There is a route to Philadelphia from here which is bad in wet weather but otherwise fair. It lies through Riegelsville, Durham Furnace, Plumsteadville, Doyleston, through Willow Grove, and straight on into Philadelphia.

A Point for Discussion

Editor THE AUTOMOBILE:—I noticed in a recent issue of THE AUTOMOBILE a reprint of an article entitled "Carbureters for Kerosene," which had been published in a foreign paper. This seems to be regarded as pretty near an impossibility, but there is a design of easy and cheap construction that will readily permit of burning kerosene alone without any hot-air or hot-water appliances for its vaporization, with the engine developing decidedly more power than it would with an equal amount of gasoline. I have had such a carbureter in use for over 2 years and it is not as complicated as the average gasoline carbureter but will readily vaporize gasoline, benzine, alcohol, turpentine, kerosene, etc. With this carbureter, one of the fuels can be used after the other without any adjustment save a slight alteration of the needle valve. Alcohol requires a larger opening than gasoline, benzine, turpentine or kerosene, having more heat units per unit of volume. While I have not been able to start with kerosene on a cold engine, it only requires gasoline for the first two or three revolutions and will then fire with kerosene, whether the cylinders are warm or cold. With gasoline, it starts even in zero weather. With a mixture of one-fourth gasoline and three-fourths kerosene it starts without trouble even at a temperature considerably below the freezing point of water.

But now the question is this: Of what use would such a carbureter be to the average automobilist? Those who use kerosene vaporized by a special carbureter say that it fouls the cylinders, thereby diminishing the efficiency of the engine. THE AUTOMOBILE recently stated that the S. A. E., in a discussion of carbon deposits, brought out the statement that "the carbureter did not furnish enough oxygen for all the fuel and the sub-oxidized product was deposited." I would not like to contradict that, but it is, in my opinion, more the fault of the engine design which retains a portion of the smoke of the previous explosion in the combustion chamber which ultimately causes a deposit, as I have an engine in which an air current passes through the cylinder after each explosion, completely scavenging the cylinder of all foul gas. In over 2 years' service, I have had no deposit, though often using only kerosene for fuel and the cheapest grades of machine oil as a lubricant. I would like to see a further discussion of this point by others who have had experience.

Bradenville, Pa. JOSEPH MUNDEN.

Concerning State Touring Laws

Editor THE AUTOMOBILE:—I intend to make a tour through Arkansas, Missouri, Illinois, Indiana, Ohio, Michigan, New York, Pennsylvania and Maryland and would like to know the requirements of each state as regards tourists.

Paragould, Ark. J. R. BERTIG.

—Inferring that you mean the requirements of non-residents passing through each of the states you mention, the provisions are as follows:

Arkansas—Non-residents exempt from license fees provided that they are properly registered in their own state.

Illinois—Non-residents may tour in the state for 60 days each year without further registration than in home state. That is, home registration suffices.

Indiana—Non-residents exempt from registration.

Maryland—Two periods of 7 days each are allowed.

Michigan—Reciprocal with home state. You need not register to tour through the state.

Missouri—Nineteen days allowed per year without registration.

New York—Reciprocal arrangement. You need not register.

Ohio—Non-residents are exempt from registration.

Pennsylvania—Ten days are allowed per year.

You can, therefore, tour through all the above states provided you are registered at home, without paying any other license fees. The rules of the road are practically the same in all, although the speed limits differ in the various states. They are as follows, in miles per hour: Arkansas, 20; Illinois, 25; Indiana, 20; Maryland, 25; Michigan, 25; Missouri, 25; New York, 30; Ohio, 20; Pennsylvania, 25.

Trouble with His Spark-Plugs

Editor THE AUTOMOBILE:—I am having trouble with the spark-plugs on my automobile. Almost every trip I take the engine will begin to misfire after I have run between 2 and 50 miles. On every occasion I find on examination that a broken porcelain is the cause of the trouble. I have used several makes of plugs, but all give the same results. My engine does not heat up very much, not so much as a great many others I know of that never have any spark-plug troubles at all. Will THE AUTOMOBILE tell me what to do to avoid the trouble? The car is a 1910 Patterson touring.

Boonville, Ind. W. L. MARTS.

—You are probably putting the plugs in too tightly and then, when the motor heats up, the porcelains crack. This and overheating are the only two reasons that cause plugs to crack while in the cylinders. There is a great possibility that the spark-plug apertures have not been tapped large enough so that it requires a great amount of force to get the plugs into the cylinders. If you run a tap of the correct size into the hole in the cylinder and then apply the plugs without using a great amount of force there is no doubt that your trouble will disappear.

Has Firm Belief in His Motor

Editor THE AUTOMOBILE:—Your cry for a little less toothache will go thundering down the ages as a modern classic. A little less radiator when you could do without one!

Reader has not read my letter; at least I do not see where he has pointed out "obvious answers to many of my arguments from daily practice." "Why citing the Franklin car?" when I had stated that the engine was designed for city gas and ran now with waterjacket empty. "Why referring to the elaborate cooling means of another?" when I do not complain but of not enough heat. As to the engine: It had run about 10 years before it came into my hands, using tube ignition. I have never given the bore and stroke any consideration since it did not interest me. It is a so-called stationary engine of the horizontal type and very heavily built, the inlet valve being automatic and both valves in the head. A waterjacket encloses almost the entire cylinder, excepting about 2 inches in front. I took out the hot tube and put in 2 plugs in series, a system I have found excellent for 3 years.

For what reason does Reader expect oiling difficulties when I have injected water with the fuel into the engine and have seen it come out as water instead of steam, as alleged by some? Then I was entitled to take the step and raise the temperature of the engine; then I am entitled to double this temperature in the near future. I had thought I could turn water into steam and thereby get a steam-engine effect, an extended push, but I failed. I had much rather have a definite reply than mere generalities. Why have I failed, where others have succeeded? Under what conditions have they accomplished it? I had a serious setback 3 years ago when I took water into a four-cycle gasoline engine by means of a second carbureter. The engine came to an abrupt stop in about 5 minutes and a 6-foot lever would not move it. Examination the next day showed the water in pools, the oil no longer forming an unbroken film, and each pool full of rust. I do not know to this day what really did take place. I mean I have not the slightest hint as to the causes. If anyone has any such an experience, or can form any conclusion from what I have said here, I would be pleased to hear from him. Water injection for cooling purposes is entirely feasible and works very well. It is less cumbersome than the radiator, but as the motor is ordinarily arranged it would not be advisable to use this system unless provisions are made so that the fuel ceases with the water. I mean, should the water fail, the engine might get damaged and the failure of the one must cause the other to be cut off. This, of course, the average man cannot readily accomplish.

The pious wish of Reader to have radiators investigated tempts me to believe him a layman Simon-pure. Investigations are handled thus (so I am entitled to say from answers I received from universities and similar institutions): A university professor is privately engaged (the institution as such never makes tests) to make a certain test. The professor, then after the price has been agreed upon, uses the quasi-public apparatus of the institution as if it were his own and gives a report as favorable as possible towards his employer. I gave a gasp of surprise when I got those answers. The sooner such a system is abolished, the better. I ask with Pilatus, the governor of the conquered province Judea, "What is the truth?" I believe with him that truth is like the fleeting hour, a mere mark, a token—but we should eliminate the human factor and induce the institutions, as such only, to make tests.

But, dear Reader, what will the professor accomplish whose all too trained mind permits him to see but a very narrow horizon and whose helpers, the students, are but in the forming periods of life? He will do as all those before have done; he will report that he has followed the trail blazed by the—well, must I say the hated word?—inventor, and that he found it of such a length and counted so many landmarks! If not truth, but the better vision, lay but an inch to one side of that road, how could he see it? He can but follow the trail—science has always done that. To cite an instance: It had been mathematically proven that flight by mechanical means is and always would be impossible. I believe "science" one of our most inefficient branches of human endeavor.

The question of radiator is safer thrashed out here. But what I thought would happen did happen: The men who ought to take this question up, the designers, do not consider the art. They consider themselves. But, with shame, we must confess that practically all progress is imported. It is of no use and of still less sense to meet such a statement with the usual: "Hurray for

Fig. 1—The roads that a Birdell, Pa., man has to contend with

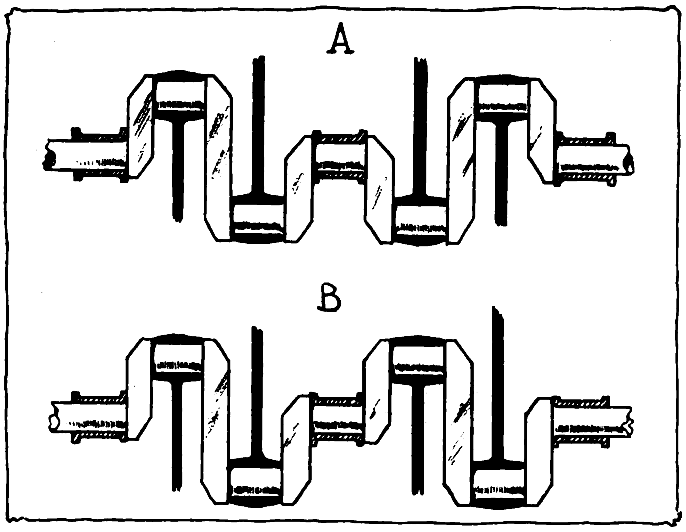

Fig. 2—Two types of crankshaft suggested for four-cylinder opposed motor

the red, white and blue." Successes in the United States are won by brute strength and at the expense of an enormous waste of human material, a parallel of the gas engine with an efficiency of 25 per cent. Although considering at all times that we can get but a mere fraction of a return for our efforts, it behooves us to reach out for the light in the distance, however small. When I speak of an engine as I did, I naturally speak of things as they are. But it may be a mere isolated instance; it may be of no significance; it may be entirely impossible to duplicate it with an engine of different bore and stroke. The engine now runs on any old thing. I have tried about all the fuels I could get, some of them of great difficulty to procure—crude oil, for example. But an engine differing but little may not do this. If so, it is worth knowing.

Great doctors in the past have disagreed. An English designer of reputation, in his latest book, says that he is right now, as he was then, and Mr. Otto was wrong. Otto held the layer theory; the other refutes it. Let me add to the gayety of nations by saying that the truth lies nearer between them: The mixture at the time of the firing has several zones which are not as easily definable as Otto would have us think. If I am led to think, by the failure of water to turn to steam, that water at once clusters in uneven films on the cylinder walls when entering the cylinder, would you then call my trend of thought unreasonable? Have I not the good reason that only the hugging of the water to the iron can permit the water to survive the high temperature of the firing? How am I going to explain the fact that when starting the engine from cold, feeding it crude oil, that it will fire but every sixteenth revolution, the crude oil passing out of the exhaust, unburned? How am I going to explain the fact, that with a hot engine, I may souse the cylinder with crude oil, then shut off the supply and have engine run for a while and it takes each fire, firing in orderly manner as much of liquid as it requires, leaving the rest unburned? But one conclusion I see at this writing: That the walls of the engine have a protecting sphere of influence. Whether this definition has any better chance to make things clear it has helped me to conclude. When I pointed out that the maximum wave of compression does not coincide with the rear end position of the piston, I hoped that some one would point to the Diesel engine. That engine, because of its function, cannot have this defect. To what an extent has that helped the general efficiency of that engine? I may be entirely wrong when I surmise that an improvement in engines is bound to follow with its circumvention. One but has to look over the efforts to improve engines by more perfect scavenging and the failure of those efforts to look askance at an attempt towards improvement in that direction.

That the spent gases are not as detrimental as generally conceded, my own investigation has permitted me to conclude, and at a later day I will gladly take up that question, going into it fully. I found it a very interesting study, permitting improvements in engines in a direction perhaps but little considered. I can frankly say that, although at times I thought I knew about all there was to be known of gas engines, the deeper I got into it, the deeper I found the waters. I had hoped for a fight and what do I find: Those who know nothing of the subject say nothing. Those who do know fear to part with their knowledge—a deplorable admission of poverty.

New York City. P. G. TISMER.

Which Is the Better Crankshaft?

Editor THE AUTOMOBILE:—I am sending you two sketches of a crankshaft for a four-cylinder, horizontal opposed engine, Fig. 2, A. and B. I would be very much obliged if you would advise me of your opinion of these two with reference to which is the better balanced and any other features that you may know regarding the relative operation of the two.

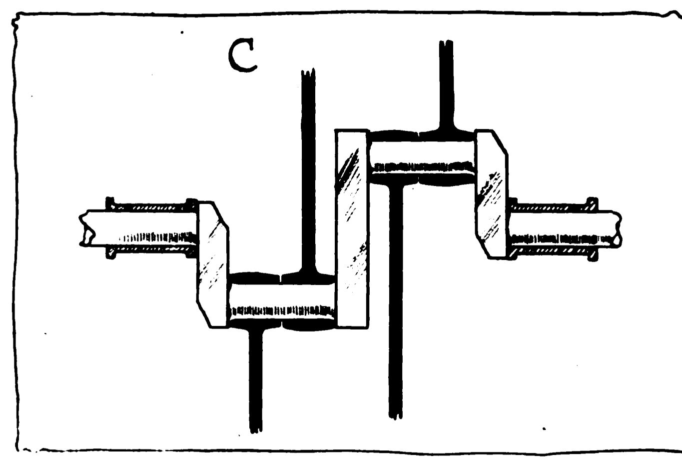

Fig. 3—More compact form of crankshaft which could be used for opposed motor

Hanover, Pa. R. M.

—Neither of these two rigs would be very good from an engineering standpoint, although the one shown at B with the two cylinders alternating would be better, because you would have the same distance between the cylinders. If you used the other crankshaft shown at A, you would have a wide space between one pair of cylinders while the other two would be close together. This would give a very peculiar-looking construction and would not produce very good results. The best way would be to arrange the crankshaft as shown at C. The engine would take up less room, the same casting would suffice for both pairs of cylinders, the construction of the waterjackets would be simpler and a much more satisfactory engine all around would result.

The firing order could be practically as you desire only that alternate cylinders would have to fire after each other. The firing could be 1-2-3-4 or any other way that the builder chooses, depending on the arrangement of the cylinders. The cylinders could be readily cast in pairs and the cost of the engine reduced considerably, while the simplicity would be much greater than if each cylinder were cast singly.

Brake Horsepower Not Known

Editor THE AUTOMOBILE:—Please tell me through THE AUTOMOBILE the actual brake horsepower of a four-cylinder motor of 3 1-4 inches bore and 5 inches stroke?

(2) Is a two-bearing crankshaft as good as a three-bearing shaft?

(3) What are the advantages of a floating rear axle over a semi-floating?

Wyandotte, Okla. C. R. SCOTT.

—(1) It is impossible to tell by formula or any such means the actual brake horsepower of a motor. The brake horsepower is the amount of power measured on a brake such as the Prony or any of the other forms which are in use in testing plants. The brake horsepower of such a motor as you describe may vary in such wide limits that it is impossible to state what the brake horsepower would be at any given number of revolutions per minute.

(2) Two-bearing crankshafts are used on light cars and have the disadvantage that great strength is necessary so that there is no whipping action in the crankshaft. In good cars this is taken care of by a generous bearing width in the two bearings. The simplicity of construction required with the two-bearing shaft is a great point in its favor.

(3) This is a matter which is still being thrashed out among the car manufacturers. Prominent manufacturers are using both and it is impossible at this time to state which is better. The floating type has the advantage, however, that it is possible to get at the driveshafts much easier. All that it is necessary to do in this type is to remove the hub cap and withdraw the axle shafts and the weight is entirely removed from the driving mechanism, being taken altogether by the housing of the rear system.

Suggests a Repair Shop Kink

Editor THE AUTOMOBILE:—I would offer a little tip for repairmen who do a great amount of work on crankshafts. This part is very clumsy to handle on the bench and may be damaged if a vise is used carelessly. I have rigged up a little bracket which I place in front of the bench as shown in Fig. 4. It is bolted to the floor and the crankshaft is held fast by means of

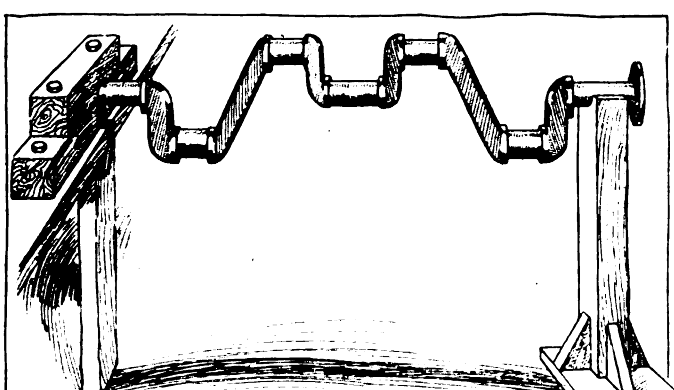

Fig. 4—Handy method of holding crankshaft suggested by Beloit repairman

the bolts which pass through the blocks on the bench. In this way, fitting and measuring can be done very conveniently and without danger of doing any harm to the part. The shaft can be revolved at will and is in a convenient waist-high position.

Beloit, Wis. REPAIRMAN.

Device for Piston Oil Groove

Editor THE AUTOMOBILE:—The cut of the groove for preventing oil working past the piston rings which you gave in your issue of June 27 does not show the best form of the device.

My experience has been that, in most cases, a groove of about the dimensions shown in Fig. 5 is sufficient without the holes leading to the interior of the piston. The essential feature is the exposure of the lower edge of the ring, the sharp edge of which scrapes the excess oil off the cylinder wall on the down stroke into the storage space provided by the groove. At the bottom of the stroke the inertia of the oil and the upward movement of the piston crowd the oil into the sharp lower part of the groove, where it tends to distribute itself upon the cylinder wall as the piston moves upward.

There is a ratchet-like action, tending to work the oil away from the combustion chamber but not removing the oil from the cylinder wall, where it is wanted both for lubrication and as a packing. A very gradual approach between the piston surface and cylinder wall at the bottom of the groove is the secret of success with this device and it is well to round off the junction line of the piston with a file.

In those exceptional cases where this form of groove does not take care of all the oil, diagonal holes may be added as shown in the second sketch. It is not necessary to add a ring at the bottom of the piston as the groove can be, and usually is, applied to the ring next to the wristpin. These grooves are broadly covered in my patents numbers 908,569 and 908,570, and, while I do not wish to be taken as authorizing their general use in manufacture I should be glad to have individual owners avail themselves of this improvement while overhauling their cars as I think it well worth while.

Akron, O. F. D. HOWE.

Advantage of Hand Air Control

Editor THE AUTOMOBILE:—Please tell me through THE AUTOMOBILE if it would be advisable for the sake of economy to put a hand control for extra air supply on the carbureter of a model T Ford, 1912.

Buffalo, N. Y. H. J. DOYLE.

—It would not be economical because the carbureter now on your car is sufficient for all touring purposes and if you desire to use it for racing you would have to buy a larger waterjacketed carbureter in the first place, and would have to make a number of other adjustments outside of the carbureter as well in order to put on such an arrangement.

Likes Interconnected Oil Device

Editor THE AUTOMOBILE:—I think that every one should heartily indorse the idea which seems to be coming to the front now in the automobile field of interconnecting the throttle with the oiling device. That is, should the car be running slowly there will not be nearly so much oil fed to the cylinders as when running rapidly. Little things like this must mean a lot of difference in the expense at the end of the season. In going uphill also with the throttle open wide and the motor running slow more oil will be fed, which will be just what is desired.

Milwaukee, Wis. READER.

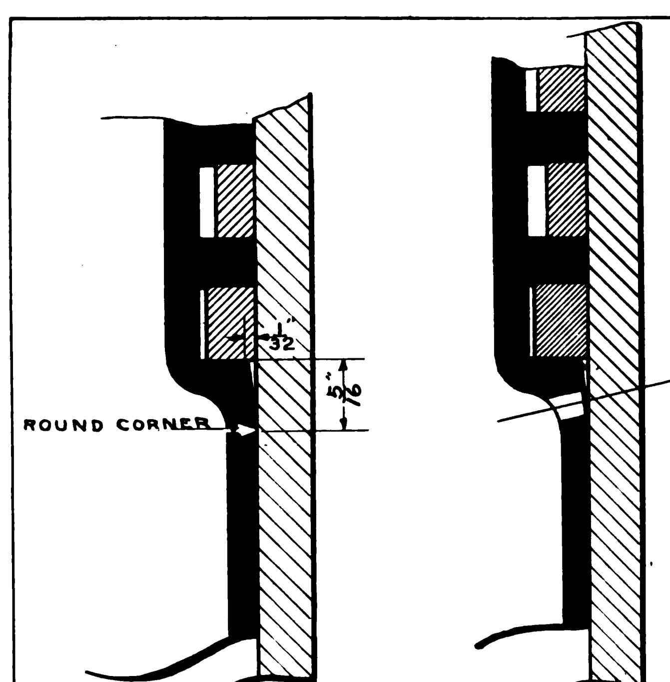

Fig. 5—A device for preventing oil from working upward past the piston rings

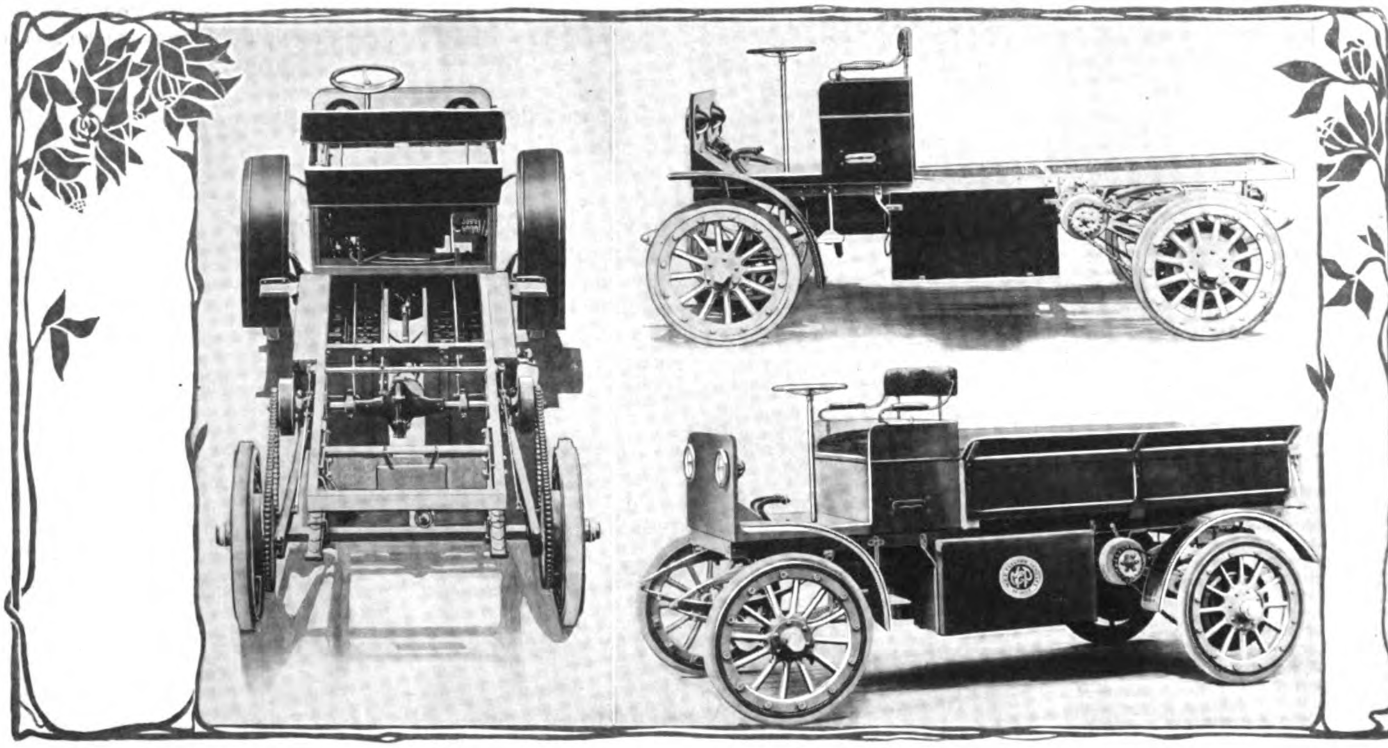


Rear and side views of the new 1-ton M. & P. electric truck. Express style of body mounted on chassis

M. & P. Electric Truck

Detroit Concern Has Added 1-Ton Vehicle to Its Line—Will Continue 1000-Pound Wagon

General Lines Similar to Those of the Latter—Traveling Radius 50 Miles Under Normal Conditions

THE M. & P. ELECTRIC VEHICLE COMPANY, Detroit, Mich., will be in a position to make deliveries on a new truck within a month. Up to the present time the company has confined its energies to the making of a single model, a 1-2-ton type, but its plans are all complete for the manufacture of a 1-ton design in addition to this earlier model.

The new truck will maintain the general features of the lighter model, although it will be longer, will have a larger battery and other parts will be correspondingly altered to be consistent with the greater carrying capacity.

The motor of the new truck will be a Westinghouse, type V-50, the voltage being 80 and the amperage 30. The speed of this motor is rated at 1,500 revolutions per minute under normal conditions. It is mounted forward, under the seat, the shaft from it to the jackshaft passing back between the two battery boxes which are located amidships under the frame. This construction is the same as that employed in the 1-2-ton truck. The controller, which is also placed under the seat, is of Westinghouse make, type 501-F. It is designed to give continuous torque, there being four speeds forward and two reverse.

As in the smaller truck of this make, the battery is of Gould manufacture, having forty cells, with thirteen T. H. plates per cell. The connectors are of the L type. The mileage per hour with this battery and fully loaded truck is 9 miles, while that on a charge is given as 50 miles, under normal service conditions.

The drive has already been partially mentioned. The first reduction is to the jackshaft, the propeller shaft from the motor being of large proportions. It is of square section, 1 1-4 inches in size. Two universal joints are used with this shaft, one being placed just to the rear of the motor and the other at the differential. As in the usual construction, two side chains transmit the power from the jackshaft to the rear axles, the gear reduction between sprockets and pinions being twelve to one.

The jackshaft is of the live type of Weston-Mott make. Ball bearings are used on the third-arms, which are also of this concern's manufacture. On the sprocket ends Hyatt roller bearings are used. The parts of the shaft, differential, brake rods and holders, as well as the battery, are easily reached on removal of the floorboards. Grease-cups, however, for lubricating the shaft bearings are reached from the outside of the machine, as the chassis view shows.

Both axles are of Weston-Mott make, the rear one being of square section of the dead type, 1 3-4 inches square with spindles 1 3-4 inches in diameter. Side radius rods of substantial proportions pass from the jackshaft mountings between the service brake drums and the frame members to the rear axle. The front axle is of I-beam section, 2 1-2 by 1 1-2 inches, the spindles being 1 5-8 inches in diameter.

Elliptic Springs Are Used

Springs are elliptic, the front being 36 inches in length with a width of 2 inches. In the rear they are 40 inches long and have the same width as the front springs. These rear springs rest on the axle and are fastened to it in the usual way with clips. They are fixed to the frame at their upper sides in special adjusting supports which allow them to slide back and forth to take up jars due to unevenness of the road. At the same time the radius rods at each side maintain the alignment and relative distance between jackshaft and rear axle.

There are two sets of brakes, the emergency and service brakes. The service types expand in drums at the outer ends of the jackshaft between the frame members and the chain sprockets. They measure 10 inches in diameter and have a width of 2 inches. The emergency brakes are also of the expanding type, measure 14 inches by 2 inches and are located in drums mounted on the rear wheels. The operation of both sets is by means of pedals which are located on the floor forward of the steering column.

The frame is of standard 4-inch steel, channel section, having a length of 147 inches and a width of 32 inches. The cross-members, of which there are three, one at either end and one just forward of the jackshaft, are also of 4-inch, channel-sectional steel, hot-riveted to the side-members.

The wheels are of the artillery type, having twelve spokes, 1 3-4 inches in diameter. The bearings are of Weston-Mott construction. Wheels are made according to S. A. E. specifications, both front and rear being 34 inches in diameter. Tires are of Firestone solid type, 34 by 4 inches, mounted on demountable rims.

The wheelbase is 112 inches, a 2-inch increase over that of the 1-2-ton truck of the M. & P. make. Tread is 56 inches and the road clearance 11 inches.

While the over-all dimensions of the truck will vary somewhat, depending upon the type of body mounted on the chassis, with the standard type of delivery body the over-all length is 158 inches and the width 68 inches. The over-all height from the ground is 91 inches. The loading space back of the seat is 100 inches in length, 45 inches in width and has a height of 58 inches. These dimensions apply to the clear space within the body.

The total weight of the new truck is 3,800 pounds when equipped with the standard type of body.

Wear and Tear of Armored Tires

How the high speed, fast turns and abrupt accelerations and retardations of a race make short work of destroying a tire armor—and a road surface—is revealed by an inspection of the accompanying illustration representing the wheels removed from the victorious Boillot's car during the recent two-day Grand Prix race over the Dieppe circuit in France, covering a distance of 1,550 kilometers or 960 miles. On some of the stretches the speed frequently reached up toward 100 miles an hour, and the enormous pull which such going exerts upon the anti-skid rivets is in evidence especially on the second and third tires from the right. One of these, the third, went through 12 of the 20 laps, or a distance of about 576 miles, and more rivets are missing in it than in any other. It shows both wear and violence. It is evident that the rivets are very rarely yanked out by the traction pull until after they have first been worn down and wiggled loose. The big rivets are worn almost to the size of the small ones, but a certain irregularity in this matter shows that the traction-thrust of the rivet heads against the stones of the road after all have more to do with the havoc wrought than the steady wear and the mileage; in other words, that the pulling out of rivets in anti-skid tires is distinctly a racing result which need not be feared in travel at ordinary speeds until much higher mileages have been covered. The smooth front tire is to the left, which was used only on the first day before the rain had set in and made the road slippery, seems to have made as good a showing with regard to surface abrasion as the armored front tire to the right, the last to be exchanged.

Switzerland seems never to be in such a happy mood as when she is bringing the iron fist down upon the automobilist. By the acts of her public officials one might be led to infer that as much as Switzerland depends upon tourists for her pin-money she really does not want them if they insist upon fetching along their motor-cars. It was only a few months ago that certain Cantons arose *en masse* and with a loud voice shouted for automobilists to keep out, because the dust stirred up by their machines was flying into the fields and ruining the blossoms on the fruit-trees and filling the grass so full of grit that the cattle refused to chew their cuds. This time Switzerland's officials purpose taxing the cars of tourists.

Chances for Foreign Trade

Items Culled from Consular Reports Showing Where Opportunities for Business Exist Abroad

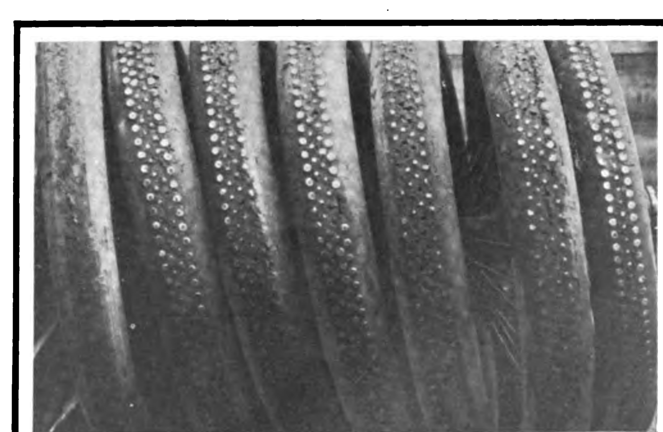
Germans Want to Import $1,000 Car—Low-Priced Automobiles in Demand—Opening for Commercials

Automobiles for Germany—An American company, which recently established an automobile agency in Germany, sold 10 cars during the first 3 months. Most of the machines sold were for pleasure purposes, but one is being used as a taxicab. An American consul writes that there are persons in his district who are willing to form a $50,000 company for importing American cars, but they desire the general agency for Germany or for all Europe, if possible. They are looking for a four-seated car that could be sold for about $1,000. American firms interested in this proposition may secure information by writing the consulate in question. File No. 9195.

Low-Priced Automobiles—An American consular officer in a European country has forwarded a copy of a letter received from a business firm in his district, requesting certain information in regard to low-priced American automobiles, and containing particulars regarding the automobiles which he wishes to handle and the conditions upon which he desires to obtain the same. This firm is anxious to hear from factories making large quantities of low-priced cars, that will do much advertising, and with which business can be done for some years to come. Copy of the letter, giving further details, will be sent to interested firms by the Bureau of Manufactures. File No. 9204.

More Low-priced Automobiles—A business in a Mediterranean country informs an American consular officer that he desires to enter into communication with American firms manufacturing low-priced automobiles, with a view to representing as agent and importing this class of machines. As the territory in which the machines will be used is hilly and mountainous, the engines must be good. Electric automobiles are not wanted. References will be furnished, and correspondence should be in Italian, French or English. File No. 9199.

Automobiles—A report from an American consular officer in a Latin-American country states that a resident of his district desires catalogues and prices for the purchase of two sixteen-passenger trucks, to be delivered in November. These trucks are to be used for passenger service that is to be established between two cities upon the completion of a boulevard now under construction. Another resident of his district desires catalogues and prices for a five-passenger touring car, to be delivered at once. Price of this car should not exceed $1,500. File No. 8,940.



How high speed pulled the rivets from Boillot's tires

Simple and Economical Motor Fire Engines Coming Fast in Germany—Construction and Equipment of Winning Racing Cars—Clutch Which Yields When Seizing —Misleading Averages in Grand Prix—Preheating of Thick Flame Welds

MODERN Fire Engines—For all accustomed to associate the idea of a fire engine with the aspect of a large steam plant on wheels shining with brass and nickel plate and spilling fire from the grate as it lumbers along the street, drawn by laboring and panting horses whose power is largely wasted in sending their own heavy bodies up and down, the simple outlines of a modern complete motor fire engine, as shown in the small accompanying illustration, Fig. 2, must be surprising. But also in comparison with chemical or steam engine equipments which are propelled by motor power, the simplification presented in the illustration is startling. The type shown in this outline has been developed at the Daimler works at Marienfelde near Berlin, on the basis of the experience gained in a number of long-distance trials of fire service vehicles conducted in Germany during 1911. Two of them are now under construction. They are intended mainly for long-distance work, as the needs of central Berlin are as yet served with electric-battery-driven vehicles in which the steam pumps are only gradually being replaced by rotary gear pumps, but similar fire engines of the pure gasoline-motor type, for powering the hose work as well as the propulsion, are being developed at other automobile factories, such as the Adler and the N. A. G. works. In the Adler engine a centrifugal pump is used, which has the advantage over the rotary gear pump or *Rundlaufpumpe* (described in THE AUTOMOBILE of July 4) that it is not positive and cannot burst the hose, when nozzles are closed or frozen, but on the other hand, necessitates the carrying of a small water supply in the vehicle to start it going, if it is to be used where no water pressure is available, since it cannot draw water from a lower level through an air space.

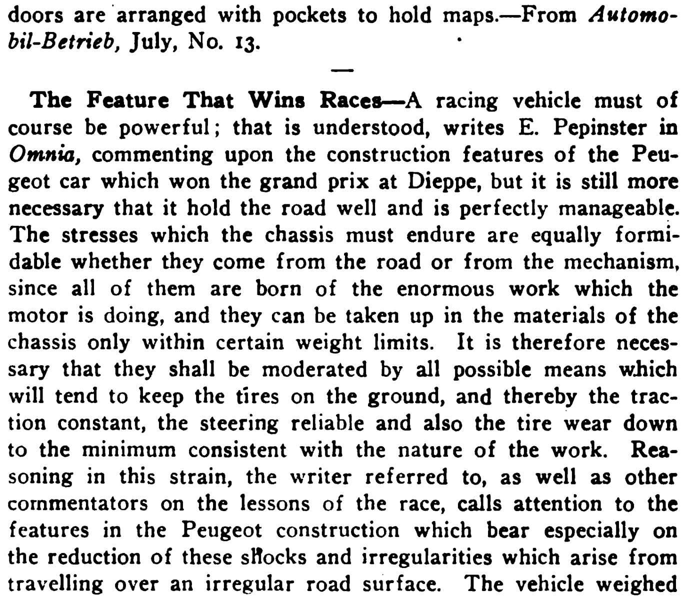
DATA OF CONSTRUCTION

The Daimler vehicles are being fitted with the positive rotary gear pump which throws 1,500 liters of water per minute. This pump is located in the rear, midway between the frame reaches and below the level of their lower edge. The rotary piston can conveniently be pulled out from the rear and cleaned of sand or other impurities which may have been drawn in with the water. Struts brace the pump against both suction and pressure thrusts and stop valve levers are mounted on the pressure struts. The driving shaft of the pump is provided with a universal joint and takes its power through the change-gear box of the vehicle, by a separate shaft, so that different pressures are available with unchanged motor speed. Other construction data are given as follows:

The motor develops 50 horsepower at 900 revolutions per minute and 60 at 1,100. It has double ignition. Auxiliary cooling of the motor (since the hose work is stationary and gives the motor no benefit, for cooling purposes, from movement through the atmosphere) is effected by leading a portion of the cooling-water around the pump while the latter is working. The vehicle speed is limited to 40 kilometers per hour by a governor acting on the third and fourth speeds.

Solid rubber tires are used on all four wheels, which are of the same size. Those on the rear wheels are of the twin type. The wheel base is 3,500 mm., the length of the chassis 5,300 mm. and the height of the chassis 760 mm. to the top of reaches. The drive is by chains. The rear girders are so arranged as to leave room between the frame reaches for ladders. The exhaust gas may be applied to thawing out the pump and its pressure-meter in winter. The lighting equipment, of especial importance for directing the work properly at night, includes acetylene searchlights in front, orientation lanterns provided with benzine gas jets and also with electric incandescent bulbs which may be switched on while the vehicle is moving, electric tail lamp, electric lamps with push contacts in the interior of the vehicle and benzine gas lamp for throwing light on the pump manometer. A Klaxon is used in addition to the customary alarm bell. The insides of the doors are arranged with pockets to hold maps.—From *Automobil-Betrieb*, July, No. 13.

The Feature That Wins Races—A racing vehicle must of course be powerful; that is understood, writes E. Pepinster in *Omnia*, commenting upon the construction features of the Peugeot car which won the grand prix at Dieppe, but it is still more necessary that it hold the road well and is perfectly manageable. The stresses which the chassis must endure are equally formidable whether they come from the road or from the mechanism, since all of them are born of the enormous work which the motor is doing, and they can be taken up in the materials of the chassis only within certain weight limits. It is therefore necessary that they shall be moderated by all possible means which will tend to keep the tires on the ground, and thereby the traction constant, the steering reliable and also the tire wear down to the minimum consistent with the nature of the work. Reasoning in this strain, the writer referred to, as well as other commentators on the lessons of the race, calls attention to the features in the Peugeot construction which bear especially on the reduction of these shocks and irregularities which arise from travelling over an irregular road surface. The vehicle weighed only 980 kilograms and was capable of going at the rate of 187 kilometers per hour on level ground. The slender frame would naturally twist more or less at humps and turns. So the motor was mounted in a false frame and the latter suspended in the



Long-distance motor fire engine with rotary pump, short ladders and hose for water supply connection main frame on three lubricated rollers with grease cups. The weight of the rear axle, with differential and Rudge-Whitworth wire wheels, was reduced to 104 kilograms, partly by the use of aluminum. Both axles were provided with shock-absorbers acting on the extension of the vehicle springs, and two leather straps moreover prevented the rear axle from exceeding a certain distance from the chassis. All the driving strain as well as torsion between the driving axle and the frame was transmitted through the vehicle springs, no torsion rods or drive struts being used, and this represents a return to early design for shaft-drive cars. [But the dimensions of the vehicle springs must naturally have been much larger than in early cars.—Ed.] The two universal joints of the drive shaft were mounted on ball-bearings. The wheel brakes (rear only) were automatically centered on the hubs and could be regulated from the driver's seat.

It is noted that, while the Peugeot car was equipped with wire wheels, the Sunbeam team of cars which won the cup for regularity in both classes and the speed cup in the race for small cars with limited cylinder volume, were mounted on Sankey wheels, which look almost like wood wheels but are composed of two molded sheet-steel shapes joined by autogenous welding. They gave no trouble.

—

Lessons of Grand Prix in France—Advocates of the style of race in which the cylinder volume of the motors in the contesting vehicles is limited have claimed as one of the advantages of this plan that it would push designers into the study of light vehicle construction, writes Henri Feron, but it is, on the contrary, the motor in which small cylinder volume is combined with high power (the pushed motor so-called) which makes for heavy construction per unit of horsepower. In the recent race on the Dieppe circuit, the powers and weights, in so far as they have been certified by the builders, were as follows:

	Horsepower.	Kilograms.
Excelsior six-cylinder car..........	170	1,600
Lorraine-Dietrich cars..............	160	1,600
Peugeot car, the winner............	175	1,400
Calthorpe, in 3-liter class...........	68	1,100
Schneider	80	1,150
Sunbeam	72	1,090
Vinot-Deguingand	50	1,100

For the three first-mentioned vehicles, which were in the class not subject to restriction of cylinder volume, the weights per horsepower were thus 9.4 kilograms for the Excelsior, 10 kilograms for the Dietrichs and 8 kilograms for the Peugeot, while, on the other hand, the weights in the limited class were 16 kilograms for the Calthorpe, 14.4 for the Schneider, 15 for the Sunbeam and 22 for the Vinot-Deguingand. The average in the free class was thus 9.15, against 17 for the limited. [The argument of the writer seems much weakened by the fact that the Peugeot motor is classed by everybody as a very much pushed motor, as it can be operated under maximum load at a speed of 2,200 revolutions per minute, a piston speed of 14.66 meters per second and a mean effective piston pressure of nearly 10 kilograms per square centimeter, and it should, of course, also be considered, with regard to the 3-liter cars, that there are very important constant elements in the weight of a car which by no means can be scaled down in proportion to the motor power. —Ed.]

From the standpoint of reliability the vehicles in the limited class also showed themselves very inferior, continues the writer. On the first day of the race 33 vehicles in the limited class and 14 in the free class were started. Those which finished were 14 in the 3-liter class, with pushed motors, and 9 in the free class, making 64 per cent. for the latter and only 42½ for the former. The second day saw the 9 in the free class reduced to 6, but the 14 in the limited were reduced to 7. Counting both days, it is thus seen that 43 per cent. of the vehicles with big motors came through, but only 21 per cent. of the vehicles with 3-liter cylinder volume. The conclusion to be drawn is therefore very plain, namely, that in order to produce a light, reliable and economical vehicle, the use of pushed motors should be shunned. —From *Omnia*, July 6.

[While the facts mentioned are of interest by showing that the small high-speed motor has not yet in all places been developed so as to equal the older type in reliability, the averages offered by the writer in *Omnia* are evidently completely misleading, as a single case of perfect reliability in a pushed small-size motor, such as presented in the case of the Sunbeam team of three cars and in the winning Peugeot car, goes much farther to show what may eventually be accomplished by all than the negative evidence of a dozen failures. Considering that all cars which finished in the Dieppe race ran for two days and over a distance of 1540 kilometers without any more attention or grooming than each driver with his mechanic could give at a sacrifice of his running time, the pushed motor may be said to have demonstrated its technical worth, as a type which will surely remain in the market on its merits, even though its commercial future may not be immediate owing to the uncertainty, in the matter of mastering the requirements in its construction, which must prevail for some time in any factory taking it up.—Ed.]

—

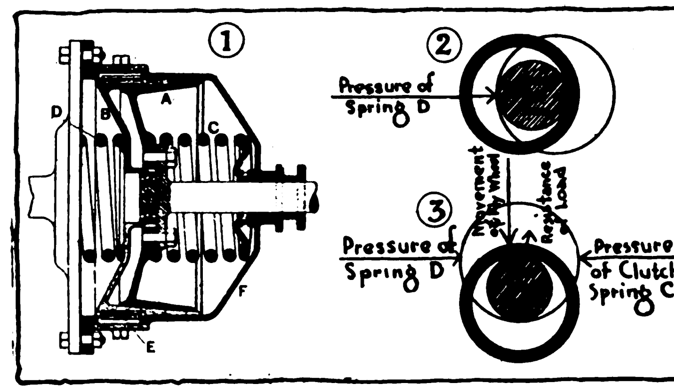


Fig. 1—Cross-sectional view and diagrams showing the operation of the Ionides gradual cone clutch

Gradual Cone Clutch Engagement—According to *Automotor Journal*, A. G. Ionides has developed for the Polyrhoe Carburetters, Ltd., a clutch design in which an entirely new principle has been applied to effect an automatic softening of engagement and disengagement. The interior surface of the flywheel is formed with a number of circular recesses, and the circumferential surface of the female cone B, which is a separate member in this design and not integral with or formed in the flywheel, is also formed with circular recesses corresponding in number and diameter to those in the flywheel. Disks E of smaller diameter, but of a thickness equaling the combined depth of two recesses, are introduced, one in each pair of recesses. [It is not explained how the flywheel and the hollow cone member can be assembled with the disks in their places, but possibly the recesses in the flywheel are made as through perforations which are plugged from the outside after the disks have been introduced.—Ed.] A spring D, which is stronger than the ordinary clutch spring C, presses the female cone to the rear, producing an eccentric relation between the recesses in the flywheel and those in the cone, as indicated under (2) in Fig. 1, the intervening disk E limiting the relation. Now, if the clutch cone is let in before the motor is started, this relation will not be disturbed, as the clutch spring is the weaker of the two. Also, if the motor is started without the clutch being engaged, the relation will remain unchanged, as there is no load-resistance to change it, save only the inertia of the female cone. But, on the other hand, if the motor is started and the clutch cone A is let in, the movement of the flywheel tends to leave the load, which acts through the disks E, behind, and this tendency assists the clutch spring C in gradually forcing the female cone toward or into a position, as indicated under (3), in Fig. 1, in which the disks E will be accommodated farther back in the recesses of the flywheel than they were at the start. As this movement constitutes a drag of the female cone in relation to the flywheel, the effect of any abrupt seizing of the clutch cones is thereby obviated; and it is evident that any sudden accelerations or retardations of the motor or the load during the operation of the vehicle will also be accompanied by a see-saw movement between the clutch spring C and the resistance spring D and a corresponding twisting around of the disks, in the recesses. It is not stated whether the chafing of spring D which must take place at one of its abutments when B drags or advances in relation to the flywheel, is taken into account in some manner, or whether it is obviated by allowing a slight torsion of this spring to take place whenever the device is acting, as referred to, in accordance with its purpose.—Partly from *Omnia*, No. 339.

—

The Next French Grand Prix—To the proposition advanced by both *La Vie Automobile* and *Omnia* to the effect that the next annual Grand Prix race in France shall be run under rules by which the cost of the speed, as expressed in the fuel consumption, shall determine the winner, Henri Petit in *La Vie au Grand Air* adds the suggestion that each vehicle shall carry four spare tires and shall finish the course without any other tire replacements. He believes a provision of this nature would stimulate tire makers to new efforts. The proposition relating to the fuel consumption has been tacitly amended by its authors so as to provide for a maximum fuel consumption which the winner must not exceed, the amendment indicating that the evident flaw in the first proposition has been promptly discovered. Owing to the progressive increase of atmospheric resistance which accompanies an increase of speed, the fastest car overcomes a total resistance which is disproportionately larger than that overcome by a slower car and naturally has to consume a disproportionately large amount of fuel in doing so. A rule determining the winner on the basis of speed divided by fuel consumption would therefore inevitably lead to the adoption of a much reduced speed, and this would rob the race of interest, both from the spectacular viewpoint and as a test of robust construction.

In *Allgemeine Deutsche Automobil Zeitung* it is stated by Edouard Pontié, the correspondent of this journal at the Dieppe race, that Benz, Mercedes and Opel cars will surely take part in the next French Grand Prix, provided the large French firms, Panhard, Renault, Brasier, Darracq and Berliet, do not themselves boycott the event as all of them did this year. All their cars must be ready 3 months ahead of the racing date, and the rules must be published very soon by the Automobile Club of France, he says, if universal participation shall be expected.

La Vie au Grand Air ascribes the poor attendance at the Dieppe race, especially on the first day, to the unbusinesslike conflict of the date with the established dates for the most important annual horse-racing events, where the fashionable world insists upon going to see and be seen. The ladies would not risk their complexions by a midsummer automobile ride to Dieppe and back immediately in advance of these hallowed functions.

—

Limitations in Use of Autogenous Welding.—Only twenty years ago soldering and brazing were the only methods in practical use for uniting two metallic parts without a mechanical joint, and the rapidity with which since then other methods have found adoption in the industries has spread the name of at least one of these modern processes far and wide. They are popularly looked upon as among the wonder-achievements of the age. The calcium light, used for theatrical effects and for throwing pictures on a screen for stereopticon lectures, had familiarized the public with the power of the oxy-hydrogen flame, and this also came into use in a limited way for cutting metals. Burglars employed it for melting out the locks of ordinary steel safes, noiselessly and therefore with safety to themselves. But, after all, this flame was not quite hot enough for expeditious work. Then acetylene gas came upon the scene, widely introduced to notice through the bicycle lamp. This gas, mixed with oxygen, doubled the heat heretofore attained by gas. The oxy-acetylene flame rivaled the electric arc with regard to the intense heat it could produce at any chosen spot and was much more manageable. Though itself made from calcium carbide and thus indirectly a product of the electric furnace, where calcium carbide is fused, acetylene gave immediate competition to electricity, both as a source of light and as a means for either cutting or uniting metal parts by fusion. Welding by the electric arc had been practiced for some time. The new competition helped to bring out electric welding by the resistance method, which was handier and better adapted to varied forms of work than the arc method. Probably the recent development of the electric furnace of the resistance type owes something to the same stimulus. For the cutting of metals the oxy-acetylene flame was from the start and still remains immensely superior to electricity. Having started to lick out a crevice it continues, without stop for adjustment, darting its hot tongue deeper and deeper as the destructive work progresses. In the work of sundering even the most refractory material it does a clean job, whether employed for crime or for industry. When it is used for fusing at the same time two pieces of metal, for the purpose of allowing the molten metal from one of the lips to mingle with that from the other, both of them to cool and harden together, the process has been designated as autogenous welding, and it is chiefly around this name, though it is very misleading, that popular interest in all the processes of kindred purpose has grouped itself. All the things which are accomplished by electric welding or by the proprietary but no less wonderful Goldschmidt "thermit" method are widely classed together with autogenous welding, giving a somewhat exaggerated idea of its wonders.

THICK WELDS TO BE PREHEATED

In reality neither electric nor autogenous welding is welding at all, since welding is a hammering process for uniting two metal parts which are very hot but not fused, and, as the term autogenous is meant to imply that no solder or spelter is used for combining the two parts, electric welding is just as autogenous as the uniting done by means of a gas flame. In recent practice, moreover, a separate weld-metal is commonly employed to assist in effecting a joint in difficult jobs of electric as well as of flame welding, and, unless this weld-metal is of exactly the same nature and chemical composition as the parts to be united, the process comes in either case nearer to brazing than to welding. Flame-cutting and flame-fusing would be more expressive terms for the work methods in which superhot gas flames are employed. While there can be only admiration for the excellent cutting that may be accomplished by this agency, it is doubtful whether for the purpose of effecting a strong joint it is superior to brazing when there is question of joining iron or steel parts whose physical properties have been improved by rolling or forging or both. The autogenous joint is always a cast-metal joint. The complete fusion of the lips destroys any properties due to a close texture, leaving after cooling only a coarse crystalline structure. If the parts to be joined are thin, the volume of heat generated by the flame is usually sufficient to effect a complete fusion of all the metal which should be engaged in the joint so rapidly that no portion of the metal will get time to harden in advance of any other with which it should be integral, but if the meeting edges are thick it is necessary that both parts should be brought first to a red heat before the flame is applied, as otherwise the exterior lips will harden and set, while the interior portions are not yet fused, and in that case the strength of the joint will be that of the fused portions only; and this precaution of preheating is often neglected. If it is observed, however, flame-welding, especially by the hot and rapid working oxy-acetylene flame, may be said to be an excellent method for joining cast iron, bronze and aluminum—these being materials which the fused weld-metal can equal in strength—but as applied to articles made from steel, especially high-carbon or alloy steel, the method is still in its experimental stage.—Partly from *La Pratique Automobile*, June.

Communications from The Manufacturer

Proper Method of Washing Automobiles with Soap—None but the Best Soap Should Be Used—Temperature of Water Important—Wood Wheel Maker Objects

THE proper washing of automobile bodies is a very important work and one which has been almost entirely overlooked in many sections of the country so far as giving instructions to chauffeurs as to how this work should be done. Often if the issuing of instructions were left to the car owner it would be out of the question, as he is not sufficiently familiar with the best methods to issue instructions.

It is safe to say that the operation of washing a car is least understood of all work in car maintenance. The proper performance least appreciated of any work in car maintenance, yet it is, so far as maintaining a good appearance of the car is concerned, the most important work on the car.

The use of soap in washing an automobile is unnecessary and ill-advised where the washer thoroughly understands his business. As it is common practice to use soap in washing automobiles and as it is not the intention of this article to advocate washing automobiles without soap, the article will discuss washing with soap.

Easiest Method Not the Best

It is common practice to adopt the easiest method of removing dirt. The easiest method is to purchase a good strong soap. This, with the use of water, at times almost hot, removes the dirt in the easiest manner. It has the drawback, however, of removing the varnish. One washing of this character will not remove the varnish, but a dozen washings will dull it and a few months will remove it, so far as the luster is concerned. A continuance of this practice will actually remove the body of the varnish in a few months more and in extreme cases of use and abuse following this practice it has been known to remove the paint itself, as some of the ingredients, acids and alkali, in the strong soap are employed in various mixtures, used for removing paint for the purpose of refinishing a car.

The use of the best imported castile is recommended. Laundry and toilet soaps are to be avoided. Automobile soaps, some good, some bad, are made expressly for washing cars. They are made in both the soft and the hard soap variety. The proper soap, principal ingredients of which are pure potash and oil, will properly clean a car, and will have no bad effect on the luster of the car. Soap that contains alkali should not be used. Any of the alkalis, either sodium or potassium hydrate or sodium carbonate or potassium carbonate, are naturally bad for varnish. Many owners have access to the services of a chemist. in which case it is very little trouble to analyze the soap. Those who do not have access had best stick to the imported castile that a high-grade dealer sells for a soap free of objectionable ingredients.

The temperature of the water used is most important. Hot or even warm water should not be used; neither should extremely cold water be used. Proper temperature is from 60 to 70 degrees Fahr. Where a hose is used, care should be taken that the force of the water is only sufficient to carry the stream 6 or 8 inches beyond the end of the hose. The use of a fast-running stream drives the grit, dust and dirt into the varnish. The use of the sponge and chamois following, picks up the grit and scratches result. In selecting sponges be careful to select the best and only those guaranteed free from grit, sand and particles of shell.

Having determined the proper soap to use, temperature of water and selection of sponge, the operation of washing should have careful consideration, as even with good soap, correct temperature and sponge, the car may be damaged by improper washing.

To properly wash a car with soap, first dissolve in a pail of water sufficient soap to make a good suds. Then in the washing operation use the suds, sopping it on from the sponge instead of rubbing the soap on a wet sponge, or, what is worse, rubbing it on the surface of the car. Before applying the suds the car should be rinsed thoroughly with water, using a gentle stream. This is important, as all particles of grit and dirt must be removed from the surface before applying the sponge. Apply the suds liberally where the parts are dirty; then rinse off with clear water and a fresh sponge, flowing the water below the sponge to insure that any grit and dirt that may be left on the surface is washed away before the sponge has a chance to pick it up and scratch the surface. After the final sponging the surface should be dried with a clean, wet chamois.

In washing the chassis, the same method is in order, except that it may be necessary to use stronger suds. Where cars are in use over oily or muddy roads frequent washing is necessary, and this washing should be done as soon as possible after the car leaves the road, as when this oil or mud dries on the car it is very difficult to remove and will damage the varnish, it being impossible under certain oil and mud conditions to remove all the stains. In this connection it is important that neither the bonnet nor radiator is washed while it is hot, as to do so will dull the luster, ruining it in a very short time.

Another point which should be given attention is that the same sponge should not be used for washing both the body and the chassis. Both sponges should be of the best quality, care being taken at all times to keep them clean and in proper condition. Owners who keep their cars in public garages will have difficulty in having their cars washed before the mud has had a chance to dry, as in most garages the washing is left until night and then put through with a large number of other cars. This method cannot be followed and have a fine-looking car.

EUGENE F. RUSSELL,
Factory Manager Locomobile Company of America.

Wood Wheels Not Specially Built

DEAR MR. EDITOR—In your issue of June 13 we notice the article headed "Testing Wheel Strength." Especially was our attention attracted by the clause about "American wheels," in which you say: "There is every reason to believe that at least the American hickory wheels ordered were the best of such kind because they were especially ordered and their purpose expressed to the maker." We think that we made the wheels in question for the Rudge Whitworth Company, Ltd., Coventry, England: but their order came to us as follows: "One wheel like blue print: order received in February." And in May, a cable saying: "Send four (4) wheels like the sample wheel."

We knew nothing of any test to be made, so there were no extra pains taken with the timber, the wheels being made in the regular way throughout. If we had known that a test was to be applied, we would have taken extra care in the selection of the wood used.

We merely mention this, as your article might give a wrong impression, detrimental to the American wood wheel as against the steel wheel.

Without doubt, the wire wheels were especially made up to withstand any test of the nature made.

HENRY P. JONES, of Phineas Jones & Co.

SAN JOSE DE COSTA RICA, July 9—Motor trucks will be assessed duty at the rate of 1.87 cents on entering this republic, according to a ruling from the treasury department.

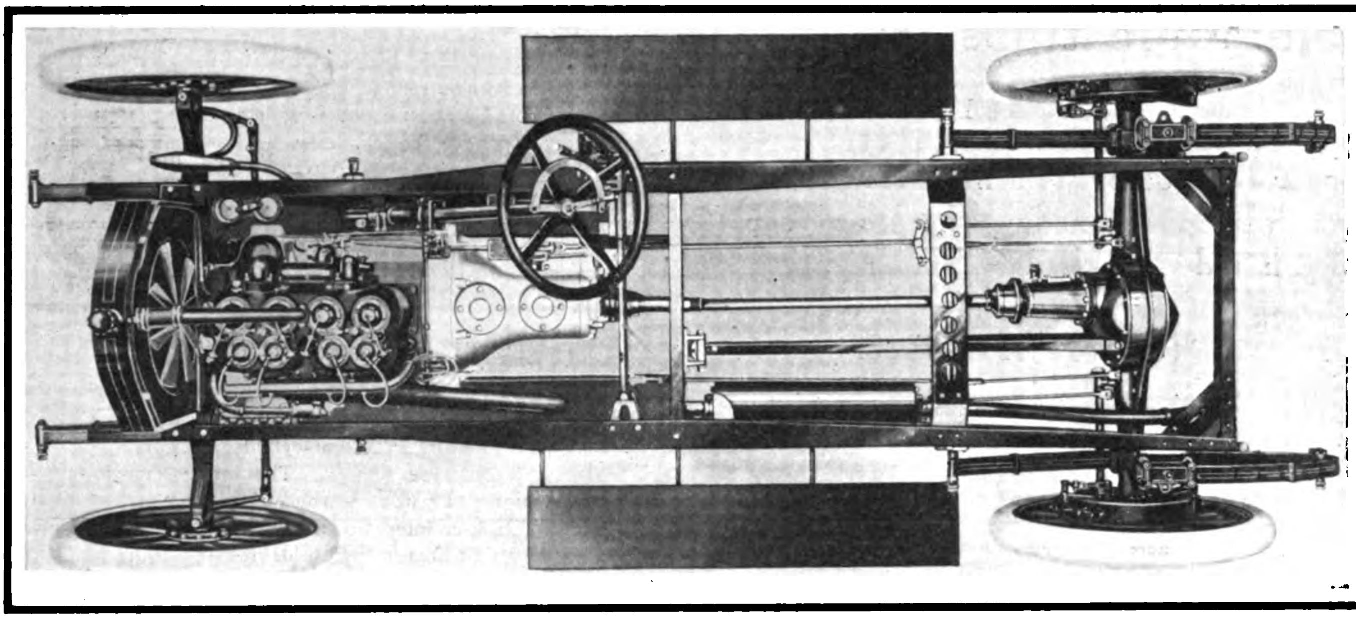

Fig. 1—Plan view of the chassis of Chalmers Model 17, 36-horsepower, four cylinders

'13 Chalmers Out

Line Will Include Two Four-Cylinder Models and One Six. Few Alterations from 1912

Reduction of Price of Six From $3,250 to $2,300 Made Possible by Standardization

CHALMERS cars for 1913 are in three models, as for the previous selling season. These are the two four-cylinder types, rated at 30 and 36 horsepower, and the six-cylinder type having a horsepower of 54. They are known as models 16, 17 and 18, respectively. The motor sizes of these cars remain the same as last year, and no alterations of their features of design have been made. In general, it may be said that the new Chalmers cars show no innovations in mechanical construction. Tried-out principles are adhered to throughout, though many refinements are to be noted.

The price of the six-cylinder, model 18, has been reduced from $3,250, the 1912 figure, to $2,300, this reduction being largely chargeable to the standardization of parts. The material enlargement of the Chalmers factory within the past year has made greater quantity production possible, and this, together with the standardization and interchangeability feature of the parts of the six-cylinder and the 36 models, has had much to do with the lowering of the price of the company's largest machine.

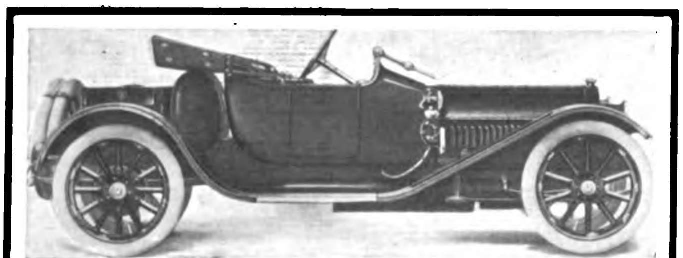

Fig. 2—Six roadster has good baggage-carrying facilities

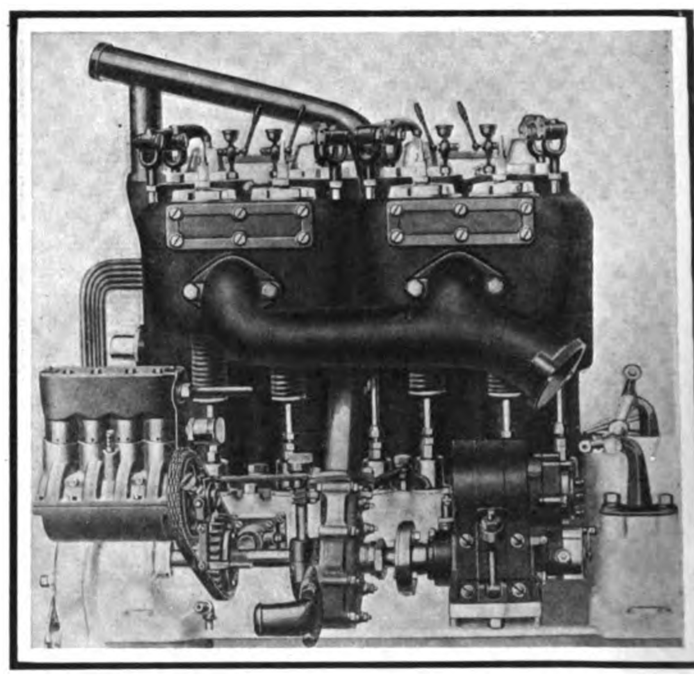

Fig. 3—Exhaust side of Chalmers 36 four-cylinder motor

The price of the larger of the four-cylinder types is fixed at $1,850 and that of the 30 remains at $1,500.

Three inches have been added to the wheelbase of the 36, increasing it from 115 inches to 118 inches. The dimension of the other two models has not been altered, that of the 30 being 115 inches and that of the six 130 inches.

No Change in Cylinder Sizes

Chalmers motors all present the same design characteristics. Cylinders of L-head type, intake valves in cylinder heads, exhaust valves at the sides, motors suspended at four points, two brackets being placed at the forward end of the crankcase and two at the rear end; intake manifolds on the right sides, exhausts on the left, pump and magneto shafts on the left, integral gear boxes, inclosed flywheels and clutches—these are features which will be found on the power plants of all three models.

The cylinder sizes of all three models remain the same as in 1912, the bore and stroke in the six and 36 being alike, but the 30

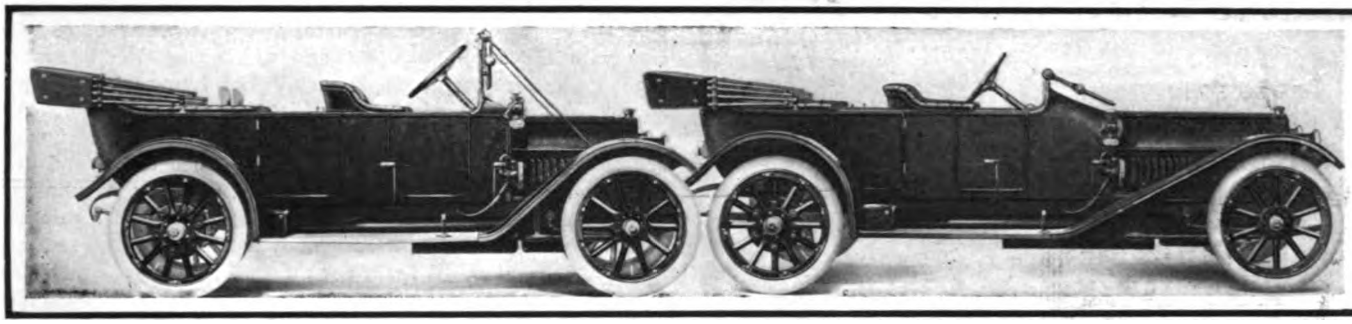

Fig. 4—Straight-line touring body features Chalmers 36

Fig. 5—Chalmers Six torpedo body with cowl dash

with different sizes. In the matter of stroke-bore ratio the Chalmers design takes a middle course between the square motor on the one hand and the long-stroke design on the other, the ratio on the six and the 36 being 1 to 1.23 and on the 30 1 to 1.12. The cylinder sizes with piston displacement are:

Model	Bore	Stroke	Ratio	Horse-power	Piston displacement
Six	4.25	5.25	1.23	43.35	446.7
36	4.25	5.25	1.23	28.9	297.8
30	4	4.5	1.12	24.80	226.2

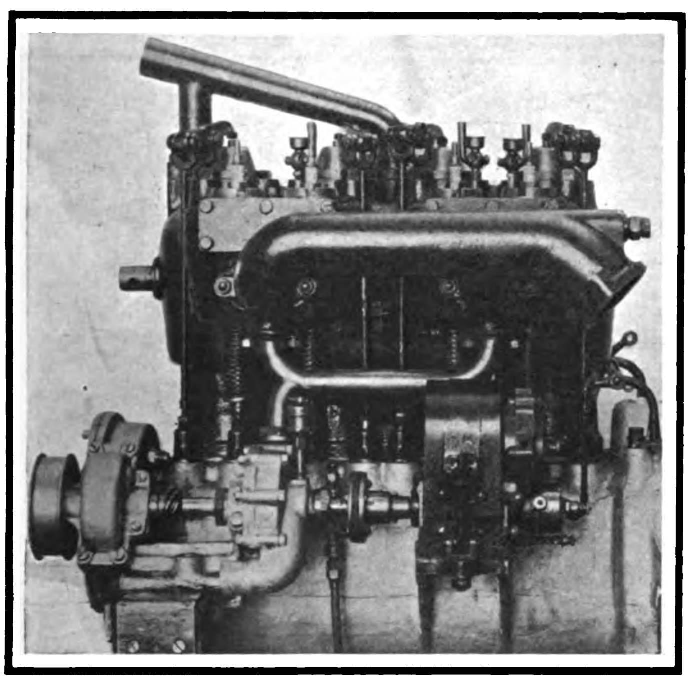

Fig. 6—Exhaust side of Chalmers 30 four-cylinder motor

Both fours use mono-block casting and the six uses groups of three. There are two intake manifold connections with the cylinders for each of the four-cylinder motors, and four for the six-cylinder type, Fig. 7. The intake manifolding of the latter is unique. From the carbureter the mixture is led into two branches, and is later divided into four before reaching the six cylinders. Exhaust manifolds for the fours are alike, there being two connections, one for each two cylinders, Fig.3. With the six there is a connection with each cylinder, Fig. 7.

Intake valves located in the cylinder heads are of larger diameter than the exhausts located in offset chambers. Nickel steel is used for the inlets, as compared with cast iron for the exhausts. Their sizes are:

Valve	Diam.	Lift
Inlet	2.25 inches	5-16 inch
Exhaust	2 inches	5-16 inch

The inlet valve springs are housed in all models and are wound conically and are operated through rocker arms pivoted on motor studs and mounted diagonally, Fig. 12. They measure 2 1-8 inch center to center. The exhausts are operated by conventional tappets and provisions are made on the intake and exhaust tappets for take up due to wear.

Liberal Crankshaft Bearings

The crankshafts of all the motors are mounted on annular ball bearings. The six-cylinder is provided with three bearings, the others having two each. On the six the ball-bearing sizes are numbered 411, 219 and 316 for the front, center and rear mountings, respectively. These bearings have dimensions as follows:

Number	Bore, Inches	Outside Diameter, Inches	Width, Inches
411	2.1653	5.5118	1.2992
316	3.1496	6.6929	1.5354
219	3.7402	6.6929	1.2598

The two four-cylinder motors have the front ends of their crankshafts mounted on No. 411 and the rear ends on No. 316.

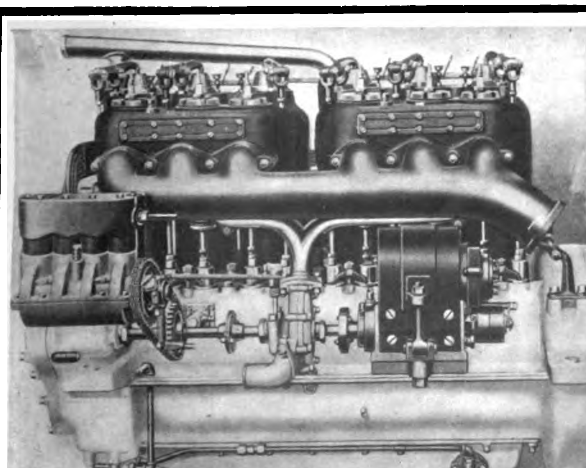

Fig. 7—Exhaust side of Six motor, showing Kellogg air pump

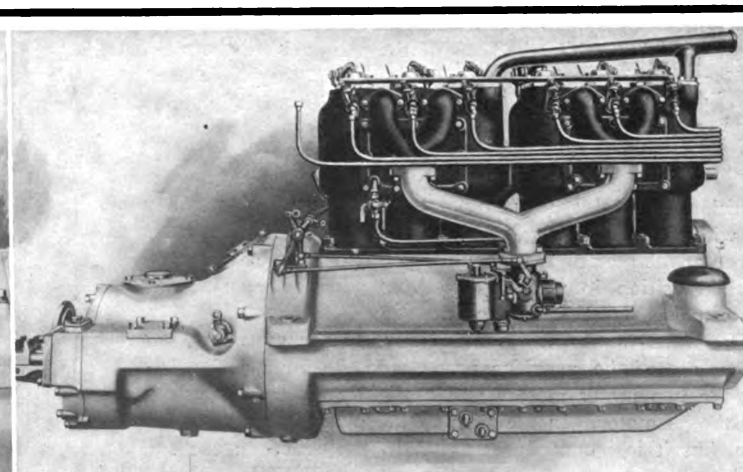

Fig. 8—Intake side of six-cylinder motor with integral gearbox

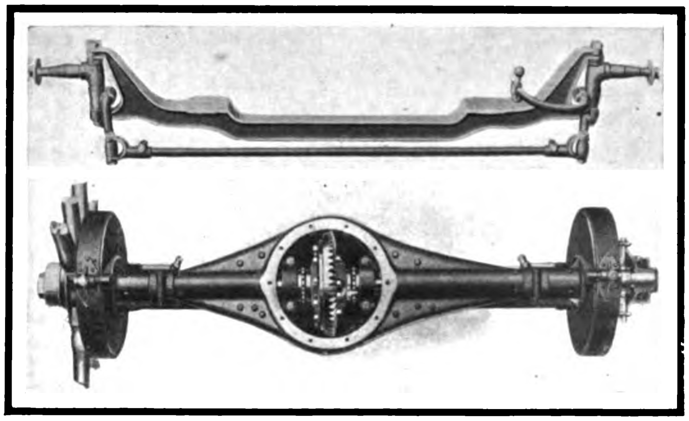

Fig. 9—Front and rear axles of 1913 Chalmers cars

The remainder of the motor bearings in all three types are plain bearings. The lower connecting-rod bearings are the same size in all motors, 2 1-4 in diameter and 2 3-8 inches in length. At the wrist-pin ends they measure 1 1-8 in diameter by 2 3-8 inches in length, and they are also uniform throughout all three motors.

Camshafts with integral cams are mounted on four plain bearings. With the shafts on the six and 36 1 1-8-inch in diameter and on the 30 7-8 inch. The bearing lengths are as follows:

Front cam shaft bearing	1 5/8 inches
Two center bearings	2 1/4 inches
Rear bearing	1 3/16 inches

Camshaft and magneto and pumpshaft gears are at the front of the motors. They are of the spur type, all inclosed by removable cover plates. The Rayfield carbureters are mounted at the right side. For adjusting the gasoline supply valve the cars are fitted with dash levers. Fuel is fed to the carbureters by pressure, the tanks being carried under front seats in touring cars, limousines and demi-tonneaus, and at the rear of the seats in the roadsters. The touring cars and limousines all carry 19-gallon tanks and the torpedoes have a tank capacity of 15 gallons. The 36 when it is fitted with roadster or coupé body carries a 35-gallon tank. This also applies to the same bodies when mounted on the six-cylinder chassis.

Lubrication of all motors is by constant-level splash system. This is of the usual form. There is an individual oil trough in the sub-base of the crankcase for each connecting-rod end. The overflow from these troughs runs into the bottom of the crankcase to a well, where it is strained, then forced by gear pump through a sight feed on the dash and back to the troughs. On the 30, 1 gallon of lubricating oil is carried in a separate tank, while on the 36 and six roadsters and coupés there are also special reserve tanks for oil. The lubricant is put into the motors through the combined funnels and breathers, mounted on the right front supporting arms. Standardization is evidenced by the fact that, while the sizes of these funnel-breathers on the two larger cars are the came as in 1912 cars, they have been increased on the 30 to the same size. A section of it is shown in Fig. 13.

Ignition Apparatus Accessible

Ignition of dual type, using one set of spark-plugs, is used, with storage battery employed for starting. The magneto, placed at the rear of the magneto-pump shaft, is easily accessible in this position from the side. A coupling between it and the pump makes its removal simple.

The water-pumps are mounted next to the magnetos. These pumps are of the centrifugal type, and the same design is used for the two larger motors and a slightly different construction for the 30 motor. In the former, the pump has a central position, but it is mounted somewhat to the front on the smaller engine.

In the Chalmers starting system silent-chain-driven, four-cylinder air pumps are located at the front end of the motor. These pumps are of the Kellogg make and they replace the cylinder check valves which were heretofore used in connection with the starting system, and which were the means of sending the air to the supply tank. The four-cylinder pumps now used pump air under pressure into the air tanks, which are placed at the right sides of the frames, opposite the running board. From the storage tank the air is piped to a distributer and from it there is a pipe leading to each of the cylinders. When the starter controller on the dash is pulled, air is admitted from the tank to the distributer, which in turn sends it to the cylinder which is ready for the working stroke. Its piston is driven down, thus revolving the crankshaft. This operation continues until the cylinders are sufficiently charged and ignition takes place.

Gearbox, clutch and flywheel are made a unit with the motor by housing them within the case which bolts to the flywheel cover. This is true of all Chalmers models. Two cover plates allow access to gears and clutch, which is of the multiple-disk type on all models. The plates are hardened and ground saw-tooth steel and they run in oil, which feature makes for easy engagement and silent running.

Of the two larger models, the four-speed transmission which

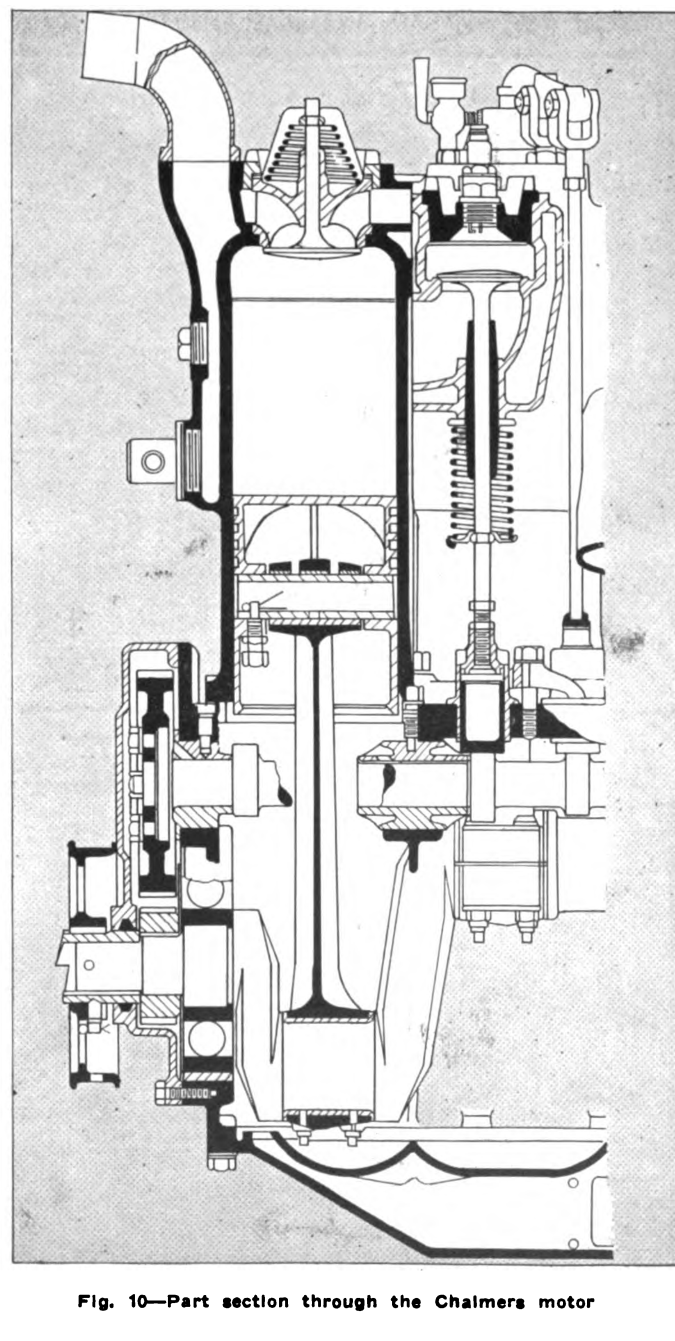

Fig. 10—Part section through the Chalmers motor

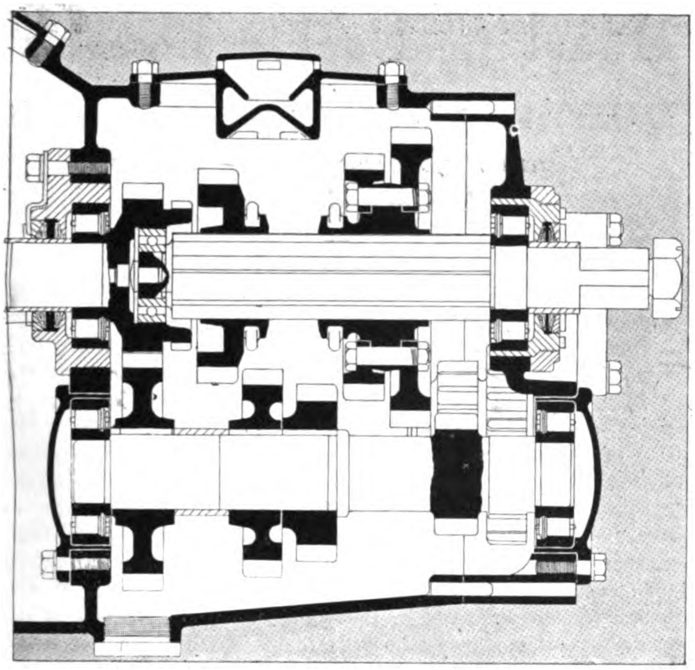

Fig. 11—Sectional view of Chalmers four-speed gearset

was inaugurated on these two types for 1912 has been continued. The 30 retains its three-speed type, also. Both roller and ball bearings are used in the gearset, the former being found at most of the points.

Power is transmitted to the rear axles of all models through shafts of ample size, which are fitted with two universal joints. One of these is mounted just back of the gearcase and the other at the differential. Pressed steel torque arms run parallel to the propeller shafts from a cross member of the frame a little to the rear of the gearbox to the differential housing. These torque arms taper so that their largest sections are at the rear, while they are swivel-connected to the cross-arms at their forward ends. This construction is carried through all models.

The rear axle is of the same construction for the three cars, a view of this member being shown in Fig. 9. It is of the floating type; that is, all the car weight is borne by the axle housing and not by the shafts. Housing is of pressed steel, heat treated. Drive shafts are of nickel steel, also heat treated, and mounted on Timken roller bearings. A cover plate at the rear permits of access to the differential.

The front axles are not of the same size of section for all the models, but they present the same design features. They are of single-piece, drop forged, I-beam construction. A view of the type with steering knuckles and cross-rod is given in Fig. 9. There is a slight drop at the center, but on the whole the Chalmers axle presents a comparatively straight appearance. The wheel spindles are fitted with Timken roller bearings. The gear ratio is 3 3-4 to 1 on all models.

Brakes are both on the rear wheels on all 1913 Chalmers models. This was true of the larger cars this season, but the 30 was equipped with service transmission brake. On the four-cylinder models the service brakes are contracting, 14 3-8 inches in diameter with a 2-inch face. The emergency expanding brakes are 14 inches in diameter with face of the same width. On the six-cylinder machine the service brakes are also external contracting, 16 3-8 inches in diameter, 2 1-2 inches in face width. The emergency internal expanding brakes have a diameter of 16 inches and the same width. All brakes are lined with a heat-proof asbestos composition and are made easily adjustable. For the fours, this brake size gives a total braking surface of 362.6 square inches per car for a total weight of 3,500 pounds without passengers. For the six these figures are 505.6 square inches surface and 4,000 pounds total weight.

Details of Frames and Springs

Chalmers frames are pressed steel channel section, the metal being 5-32 inch in thickness. They are inswept at the front ends to allow for a greater turning radius. There is a drop a little to the rear of the midway point between the centers of the front and rear wheels. Continuing to the rear, the frames have a kick-up so as to clear the rear axles. Three cross members brace the frame substantially. One of these is located just back of the gearbox, the second is placed half-way between it and the rear end of the frame, while the third braces at the rear. Triangular gusset plates reinforce this rear cross member, making it doubly strong.

Springs on all models are semi-elliptic in front and three-

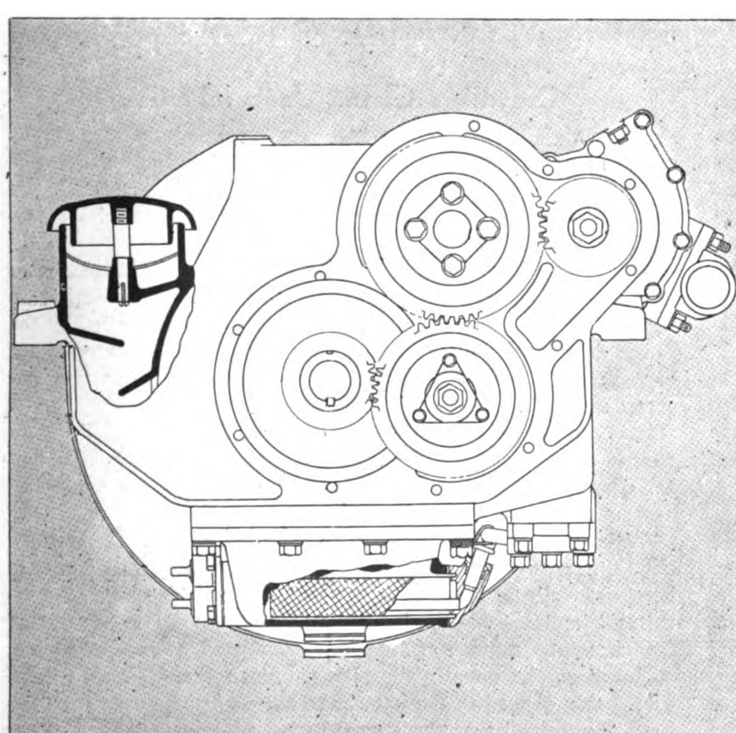

Fig. 12—End view of crankcase, showing details of oil filler opening

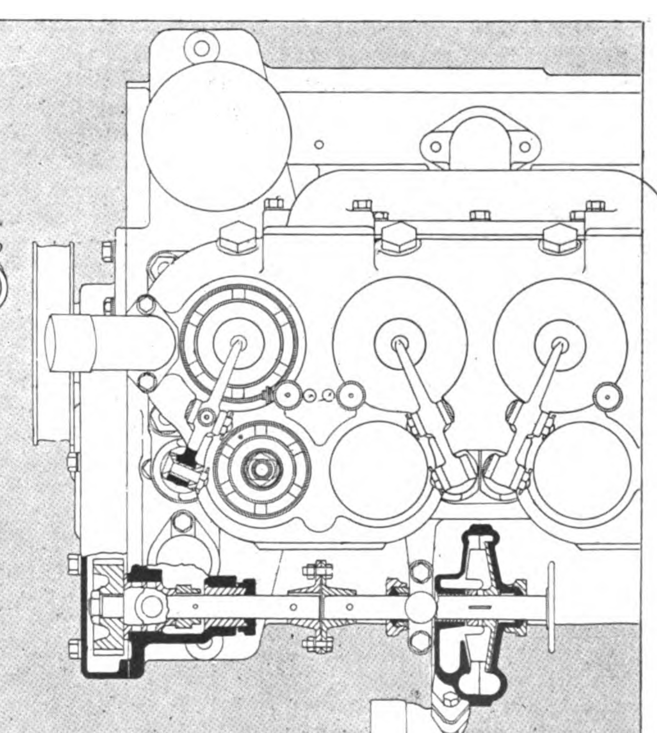

Fig. 13—Partial plan view of Chalmers motor, with water pump

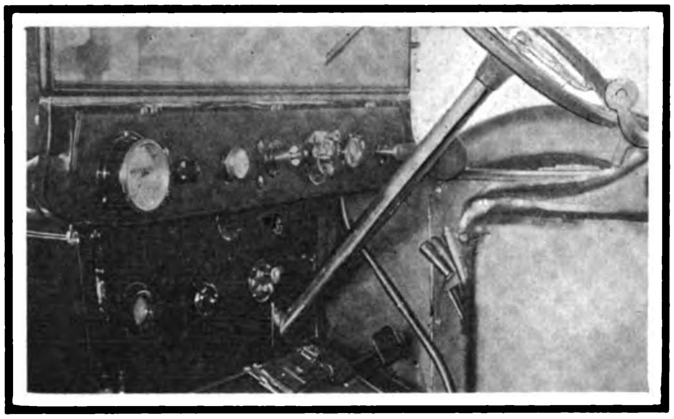

Fig. 14—Showing dashboard equipment of 1913 Chalmers cars

quarter elliptic in the rear. They are the same size on the two four-cylinder models, the front being 39 inches long and 2 inches wide, and the rear of the same width and 45 inches long. On the six, front springs have a length of 39 inches and a width of 2 1-4 inches, while in the rear they measure 53 inches in length and 2 1-4 inches in width.

Steering gears are of the worm-and-gear type, the columns being very substantial and fully inclosed. The fours have 18-inch steering wheels and the six 20-inch.

Wheels are 36 inches in diameter on the two larger cars, and 34 inches on the 30. They are of heavy-spoked artillery type, made of second-growth hickory. The hub flanges are also of ample proportions of steel. Rear wheels are flange-driven, the spokes being bolted to brake drums. On the six-cylinder type the spokes have a diameter of 1 3-4 inches. Rims are all of the quick detachable, demountable type, one extra rim being furnished. Tires for the model 16 are 34 by 4 inches all around; for model 17, 36 by 4 inches all around except on limousines and seven-passenger touring cars, which take 36 by 4 1-2-inch tires. The six-cylinder cars are equipped with the 36 by 4 1-2-inch size all around for all body types.

Much can be said as to the changes and improvements which have been made in the body designs. For the model 16 only two body types can be had, these being the five-passenger fore-door touring and the four-passenger torpedo designs. For the other two models, any style of body is furnished. Reference to the illustrations of the several body types, Figs. 2, 4 and 5, will serve to show how the Chalmers Company has worked out its designs for the 1913 trade. Bodies are all of sheet steel over wood frames, with the exception of the coupés and limousines, which are constructed of aluminum over wood frames. Easy riding and pleasing body lines have been striven for. Doors have been made wide for easy access, upholstery has been specially considered. Seats are given a pitch of 2 inches for comfortable riding. Leather is pebble-grained, blue-black, dull finished and stuffed with hair. Turkish cushions having a depth of 11 inches are used, making the seats exceedingly soft and comfortable.

The roadster designs are especially attractive, if any distinction can be made. The gasoline tank is carried back of the seat, which is provided with large doors. To the rear of the tank there is a large trunk, and back of this the tires are mounted, giving a dashing appearance to the whole car which is very attractive.

Cowl dashes are low and sweeping, and there is no wood used. A view of the dash is shown in Fig. 14. This is the same for all models. It is leather-covered, and the various gauges, switches and other appurtenances are arranged where they are easily reached. The control is on the right and the operating levers are within the body and easily reached with the right hand. As a whole, the Chalmers dash for the coming year presents a most pleasing and neat appearance besides being fitted with everything necessary to the comfort of mind of the driver.

Harking Back a Decade

What the Motoring Publications of 10 Years Ago Had to Say on Live Matters of the Day

FROM *The Automobile and Motor Review*, July 26:

Out of 138 starters in the Paris-Vienna race of approximately 900 miles, over an exceptionally rough and dangerous course for more than half the distance, 71 finished. When it is remembered that the test included the passage of the Alps, the running time of the nine leaders, ranging from 26:22:43 to 28:13:30 may be considered remarkable, especially in view of the fact that there were many neutralized points which could not be passed in less than a certain time owing to local speed regulations.

New York casualty underwriters have raised the rates on motor vehicle liability to $100 for each private vehicle, the rate 16 months ago having been only $25. The standard automobile liability policy provides that the company shall indemnify the owner for loss sustained by the negligence or carelessness of the owner or his employee, the usual limits of these policies being $5,000 for injury to one person and $10,000 for a single accident in which more than one person is seriously injured.

A little brake test to demonstrate the certainty with which a motor vehicle can be operated in traffic and the efficiency of the brakes was conducted on Long Island between Mineola and Roslyn before a group of aldermen and reporters. A fifth of a mile stretch was measured off and the time was taken with a stop watch. The trials showed that a car weighing 2,700 pounds running at the rate of 30 miles per hour stopped in 95 feet 3 inches.

Motorists have under way a movement for a protective league similar to the L. A. W. and the New Motor Union of England. The league is to have headquarters in New York and will aim to include all automobilists. There are to be consuls at all important places in the country and it will be the object to protect the interests of every member who may be arrested for alleged violations of the law. He will be furnished immediately with a lawyer and, if necessary, with bail. The league will aim to protect the cause of automobilism generally and will work for the improvement of the highways. Finally it will endeavor to secure special road rights for automobilists.

Canadians Claim Undervaluation

OTTAWA, July 19—In response to representations made by members of the Canadian Manufacturers' Association, the Department of Customs, it is understood on excellent authority, is keeping very careful watch on the valuation upon articles crossing into Canada from the United States.

The valuation of an article imported from the United States into Canada is based upon the selling price of that article in the country of its manufacture, and it has been contended by the Canadian manufacturers that the United States exporters have been placing too low a value in their invoices upon the imported article.

It is stated that the alleged undervaluation is especially common in connection with the import of automobiles, whose values are changing from time to time as improvements are made and new patents are instituted.

In the case of gasoline tractors so much in demand throughout the western provinces, the department, it is stated, has also been especially active, and a new bulletin on this class of agricultural implements has also recently been issued, on account of the enormous number of machines imported to the Dominion.

However, the manufacturers insist upon the customs regulations being obeyed to the letter, and the Department of the Customs determined that there shall be no evasion and no decrease to the protection afforded to Canadian industries.

Calendar of Coming Events

What the Months Ahead Have in Store for the Automobilist—Shows, Conventions, Race Meets, Etc.

Shows, Conventions, Etc.

July 22-27.........Detroit, Mich., Cadillaqua Week.
Aug. 5-7..........San Francisco, Cal., Pacific Highway Convention.
Sept. 17-20........Denver, Col., Convention International Association of Fire Engineers.
Sept. 23-Oct. 3....New York City, Rubber Show, Grand Central Palace.
Dec. 7-22..........Paris, France, Paris Automobile Show, Grand Palais.
Jan. 11-25, 1913...New York City, Thirteenth Annual Show, Madison Square Garden and Grand Central Palace, Automobile Board of Trade.
Jan. 4-11..........Cleveland, O., Annual Automobile Show.
Jan. 20-25.........Philadelphia, Pa., Annual Automobile Show.
Jan. 27-Feb. 1.....Detroit, Mich., Annual Automobile Show.
Feb. 1-8...........Chicago, Ill., Annual Automobile Show.
Feb. 10-15.........Minneapolis, Minn., Annual Automobile Show.
Feb. 17-22.........Kansas City, Kan., Annual Automobile Show.
Feb. 24-March 1...St. Louis, Mo., Annual Automobile Show.
March 3-8.........Pittsburgh, Pa., Annual Automobile Show.
March 8-15........Boston, Mass., Annual Automobile Show.
March 17-22.......Buffalo, N. Y., Annual Automobile Show.
March 19-23.......Boston, Mass., Annual Truck Show.
March 24-29.......Indianapolis, Ind., Annual Automobile Show.

Race Meets, Runs, Hill Climbs, Etc.

Aug. 8-9..........Chicago, Ill., Banta Trophy Match, Chicago Motor Club.
Aug. 8-10.........Galveston, Tex., Beach Meet.
Aug. 8.......... Minneapolis, Minn., Annual Tour Minnesota State Automobile Association to Winnipeg.
Aug. 10.......... Whittier, Cal., Hill Climb.
Aug. 30-31........Elgin, Ill., Road Races, Chicago Automobile Club and Elgin Automobile Road Racing Association.
Sept. 2.......... Indianapolis, Ind., Speedway Meet.
Sept. 2.......... Winnipeg, Man., Track Meet.
Sept. 3-6........ Chicago, Ill., Commercial Vehicle Reliability Run, Chicago Motor Club.
Sept. 17...........Milwaukee, Wis., Grand Prize Race.
Sept. 20...........Milwaukee, Wis., Wisconsin Challenge and Pabst Trophy Races.
Sept. 21..........Milwaukee, Wis., Vanderbilt Cup Race.
Sept. ....Washington, D. C., Reliability Run, Automobile Club of Washington.
Sept. ....St. Louis, Mo., Track Races, Universal Exposition Company.
Oct. 7-11..........Chicago, Ill., Reliability Run, Chicago Motor Club.
Oct. 12............Salem, N. H., Track Meet, Rockingham Park.
Nov. 6.............Shreveport, La., Track Meet, Shreveport Automobile Club.

Foreign.

Sept. 26-Oct. 6....Bourges, France, Agricultural Motor Car Exposition.
Nov. 8-16..........London, England, Olympia Automobile Show.
Jan. 11-22.........Brussels, Belgium, Annual Belgian Automobile Show, Centenary Palace.

Why Price of Leather Is Rising

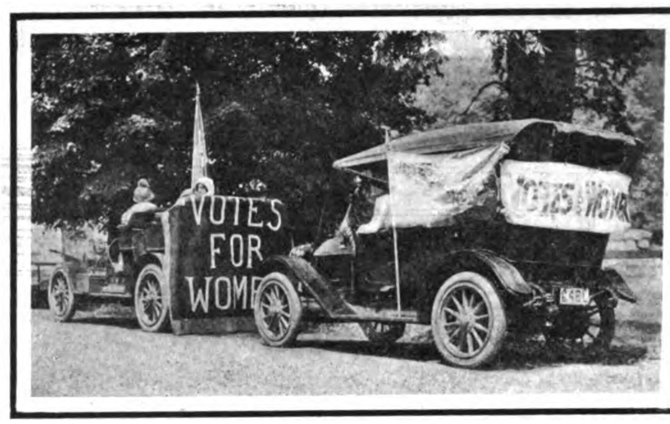
It has become one of the favorite diversons of certain interested sections of the American public to blame the automobile industry whenever the price of a staple line of material or merchandise shows a sudden bulge. Comment on leather is the latest example of this tendency to blame everything on the automobile, and its recent rise in price has been heralded broadcast by the publicity departments of several manufacturers of cheap shoes as being chargeable to the automobile industry on account of use of leather in modern automobiles.

Brewster & Company, one of the leading concerns in the country engaged in making automobile bodies, is authority for the statement that not over 10 per cent. of the American touring cars are equipped with leather upholstery; that cowhide is used mostly for such purposes and that it requires from four to five hides to equip an average touring car, thus making the average consumption of leather somewhat more than 200 square feet per car.

Cars with closed bodies are sometimes upholstered in leather, but the proportion is small as compared with the total. Runabouts and roadsters likewise are equipped with leather upholstery, but not in as large proportion as the touring car type.

The figures of the 1912 production are approximately as follows:

Type of car	Number	Amount of leather	Value
Touring cars	9,800	1,960,000	$548,800
Closed cars	1,600	400,000	112,000
Roadsters	8,200	820,000	229,600
Totals	19,600	3,180,000	$890,400



Connecticut suffragettes find the automobile useful in a campaign

L. F. Robertson, one of the prominent jobbers in leather in New York, had the following pertinent comment to make:

"All this talk about the automobile industry being accountable for the impending rise in the price of shoes is the veriest rot," said he. "It is true that 10 years ago there was no demand for leather for automobile manufacture and today it amounts to a considerable item, but the fact, so far as the rise in the price of leather is concerned, is due to basic conditions. In the first place, statistics show that there are over 3,000,000 less cattle on the ranges today than there were 2 years ago, the farmers having found that it is more profitable to raise grain or other agricultural crops than live stock. It is undeniably true that civilization has progressed and new uses have been found for leather in common with almost every other variety of commodity. The result has been not only to raise the price of leather, but also that of copper and beef and gasoline and vegetables, and poultry, and coffee and a few other things which escape my memory.

"Augmented demand and lessened supply always produce higher prices in the balance of trade. Leather is more widely used than ever before. We have a larger population and everybody wears shoes. The leather used in making shoes makes the handful devoted to automobile manufacture look like nothing at all. In my opinion the manufacturers of cheap shoes, who have not raised their prices to correspond to modern conditions, but who maintain their level of profit, or try to do so by other economies, are preparing the public mind for a horizontal boost in prices and in introducing the subject their publicity departments have taken the usual fling at the automobile."

There are two general classes of leather used in automobile upholstery work. First is the machine-buffed type, which sells at from 24 to 26 cents a square foot. The other variety is hand-buffed leather, which ranges from 28 to 32 cents a square foot. These prices are 4 cents higher than those that prevailed prior to the present agitation.

Suffragettes Use Automobile

Gaudily-bedecked automobiles are being piloted through the small cities and villages in the eastern part of Connecticut by members of the Connecticut Woman Suffrage Association who are finding that they can thoroughly cover more ground in less time in this manner than by any other means. The accompanying photograph shows two of the cars being used by the would-be voters to carry on the campaign for woman suffrage which is at present in full swing in that section of the country.

MILWAUKEE, WIS., July 22—After a hard battle, manufacturers of portable steel garages have won their fight against efforts made by the Milwaukee Common Council to prohibit the erection and use of such structures in Milwaukee. With the full consent of the chief of the fire department, as well as the Milwaukee Board of Fire Underwriters, the Council has just passed an ordinance amending the so-called garage law, permitting the use of portables.

1912 Automobile Growth

THIS week THE AUTOMOBILE presents its semi-annual statistical review of the automobile industry, analyzing its phenomenal growth during the last 6 months and contrasting this unprecedented development with that of the corresponding period a year ago. The magnitude of the industry becomes apparent not only from the tabulation of state registrations, but also from the enormous capitalization of new organizations brought into the industry during the last half year, there being incorporations to the amount of over $136,000,000 for the entire automobile field, one-half of this amount for concerns to build cars and parts and the other half for garage and accessory enterprises. Both of these items tell more eloquently than figures of cars manufactured the wide-spread permeation of the motor vehicle into every avenue of modern life.

That the automobile exerts its influence from the lakes of Maine to the picturesque slopes of California is evidenced by the fact that Maine shows the highest percentage of increase in car registration since January, 1912, the figure being over 67 per cent., while California stands second in the ranks of total registrations, being exceeded only by New York State. Agricultural improvements and developments in Maine have turned the farmer's attention to the small car, and his purchases have been a leading factor in the history of motoring in the state this season.

Another attractive example of the buying possibility of the agriculturist comes from the rich farming states of Nebraska and South Dakota, which really rank first in the columns of the number of population per car owned. The District of Columbia occupies the premier position with one car for every thirty-five population, but so many of the cars registered in the district are the property of senators and congressmen, who make the capital but an official residence, that it is unfair to other states to rank the district first. Viewed from the residential viewpoint, Nebraska shares the laurel crown with South Dakota, both of which have registered one car for every forty-five population, a most remarkable proportion. Following these are two other agricultural states, Indiana and Iowa, in both of which the agricultural classes have been heavy buyers for several year. Maine comes next and New Jersey has the honor of being the first large-registration state in the classification with a car to every sixty of population, a fact largely explained by the New York business men who make the nearby Jersey towns their residences.

States with big metropolitan centers are classed low in the car-population column. New York, with its total registration of over 92,000, has but one car for every 100 population and Illinois one car for every 120 population. The low purchasing ability of the great city masses accounts partly for this, another potent factor being the fact that agricultural New York does not purchase as many automobiles as the farming areas of the great Mississippi valley, where distances demand quicker transportation than the horse affords.

From the tabulation showing the population per car registered, the Southern States rank generally last, the explanation being the large negro population and the lack of improved highways in many of these states. Florida takes first place, with Georgia second, due in the latter case very largely to the enthusiasm engendered by the state-wide good roads fervor.

The states that head the list showing the increase of registrations from January to July over the corresponding period of a year ago is somewhat surprising. It is a medley of East and West, of North and South, of agriculture and lumbering, of cotton and corn, Maine, Oregon, Mississippi, New Mexico, Delaware, Arizona, Alabama and Nevada being the order. Each state has its reason for the unexpected increase. With one it is more general purchasing by the farmer; with another the necessity of using the car by the mining operator; with still another, the road movement. All acknowledge the automobile, all are discovering that the business of the day demands it and all are buying it.

This tabulation has a lesson for every car maker, particularly those building cheap and medium-priced machines. To many, several of these states represent much unknown territory. This is particularly so with the higher-priced makers, who have largely confined their activities to the centers of population, and when they have gone out and attempted to convert the citizen in smaller centers they have found him wedded to the medium or low-priced machine and not vitally interested in the higher-priced commodity.

The various states reap goodly harvests from the sales of automobiles, there being collected in the first 6 months of this year $4,769,873 from motor car registrations in the different states. New York contributed over $941,000 of this sum; Pennsylvania's share amounted to $525,000; Massachusetts paid out $513,000 for registrations; New Jersey added $369,000, and Illinois $305,000. It is a coincidence that in all of these states, with the exception of Illinois, the good roads movement has been making masterly headway for several years and their roads are considered the best in the land, and superior to many of the European roads. Where the increase of automobile registration and good roads building goes hand-in-hand it tells a two-fold tale—the value of good roads in the sale of automobiles and reciprocally the influence of cars on the building of highways.

Two healthy developing factors in the industry are the electric vehicle and the commercial vehicle. The motor truck shows an increase of 25 per cent. over the corresponding period of last year and with the electric there is a heavy percentage of increase. The states that are leaders in pleasure gasoline machines are also leaders in the electrics, showing the present-day tendency of many owners of gasoline machines to buy electrics for city uses, such as church, theater and shopping. The motor truck shows its major increase in New York State, but there has also been an unexpected increase throughout the smaller cities in many of the states.

Colonel Frank M. Joyce Dead

Prominent in Good Roads Work in the Northwest and Widely Looked Upon as the Next President of the A.A.A.

COL. FRANK M. JOYCE

MINNEAPOLIS, Minn., July 22—Colonel Frank Melville Joyce died at 8:25 this morning at his home here after suffering many months from Bright's disease. Colonel Joyce was one of the best-known motoring enthusiasts in the Northwest and for years had been a leading spirit in promotion of motoring enthusiasm, good roads and motor legislation in the state. He was at the time of his death first vice-president of the American Automobile Association and has been generally looked upon as a successor to President Hooper, of the A. A. A. in 1913. He was former president of the Automobile Club of Minneapolis and first vice-president and organizer of the Interlachen Country Club.

Colonel Joyce graduated from Indiana Asbury college, now Depauw University. He started business as teller in the Queen City bank, Cincinnati, O., and for 5 years was the agent of the Provident Life & Trust Company. In 1890 he became district agent of the Mutual Benefit Insurance Company, and 5 years later was transferred to Minneapolis, where he resided up to the time of his death. He received his title of Colonel from Governor McKinley, of Ohio. He was son of the late Bishop Isaac W. Joyce, of the Methodist Church. Throughout his life he had been a great club-man, a thirty-second degree Mason, a member of the Hennepin avenue Methodist church and also high up in the councils of the Knights of Pythias.

De Dion Buses for New York

According to a note in *L'Auto* of July 12 the Dion-Bouton company, of Puteaux, France, has received an order for 100 double-decker motor omnibuses from New York. They are to be of the same type as the Paris omnibuses of the same manufacture excepting that the seating capacity is raised to 42 by utilizing the tops of the vehicles for seats.

At the De Dion agency in New York it was stated that twenty-five buses had been ordered from the factory and that the cars would be shipped within the next 3 weeks.

Minerva-Knight Ties Hermes

Belgian Grand Prize Race Over 720-Mile Course Ends Without Decision—Mercedes-Knight Team Also Stars

PARIS, July 21—The teams of Minerva-Knight and Hermes cars tied for first place in the 2-day Belgian Grand Prize race run over the Ardennes circuit and which closed today. The event comprised 12 rounds over the 30-mile course for each day of the race, making the total distance 720 miles. Ten teams of three cars each and several individual cars started yesterday. Among these were the winning Minerva and Hermes teams and the Lion-Peugeot cars of French Grand Prize fame, a Mercedes-Knight valveless team, three Opels, three Benzes, three Excelsiors, and three cars teams of S. A. V. A., F. A. B. and Vivinus makes. Two French Grand Prize Schneiders were also entered, but did not constitute a complete team.

No Fatal Accidents Recorded

While there was not one fatal accident, one car was wrecked in the course of the race, this being a standard Ford car. The Mercedes team of cars having Knight engines, with 4.5 liters (275 active inches) piston displacement, were penalized one point due to a slipping clutch, the Opel team six points owing to varied trouble; one of the Peugeot cars was braked by its driver when the spectators rushed the track, causing the universal joint to be damaged and entailing one point penalty to its team which was eliminated when Zuccarelli, one of the drivers, experienced timing gear trouble. Besides this team, the S. A. V. A. and F. A. B. cars as well as the Germain machine were withdrawn from the race.

The cars entered were classed by piston displacement, under three classes, 2 liters, 3 liters and 4.5 liters. Each class of car was assigned a mean speed at which to make every round of the course; for instance, the 3-liter cars were ordered to maintain an average speed of 64 kilometers (38.4 miles) an hour. The rating of the cars' work was done on the following basis: The first round every day, done within the assigned time, was counted one point, and each following lap was valued at 1-10 higher than the preceding one, making the second lap count 1.1 points, the eleventh 2 and the twelfth 2.2 points.

The 48-kilometer circuit over which the cars raced lies in mountainous territory, but all told the roads are good and hard, having been put in specially fine shape for the speed trials. The cars started at Anseremme, which is a suburb of Dinant. Not far from this town the grandstand had been erected and a dangerous curve was in sight of the spectators. The first 15 kilometers were on a hard but hilly road, followed by 4 kilometers of a fine straight-away which continued to Vignee, where the course has a right angle. The course led through Anseremme, across the St. Jean Bridge which spans the Lesse, and back to the starting point.

U. S. Rubber to Expand

Mammoth Tire Factory to Be Erected, Possibly Near Chicago, to Care for Growing Business

Price of Gasoline Still on Upward Trend—House Committee on Patents Reports New Bill

ANNOUNCEMENT by the United States Rubber Company that a mammoth tire factory is to be built to augment the present manufacturing plants discloses at least a portion of the motive for the recent financial expansion of the company.

President Samuel P. Colt recommended to the annual meeting of the stockholders that $10,000,000 of liquid cash capital be added to the company's finances, but the concrete reason for the addition was not made clear to the public at the time. Now it appears that the company contemplates the erection of a new factory which will have a capacity of 2,000,000 casings a year.

While the rumored statement that the new plant would be located at Chicago and that building operations would be started in October could not be confirmed at the offices of the company, it was announced that such action was probable.

For about 2 years the tire industry has been under constant and insistent pressure in all the manufacturing departments and overtime has been the general rule throughout the industry. Some of the factories have been constantly sold ahead for from 3 months to a whole year.

In response to the announcement of the contemplated erection of the new factory, the common stock of the United States Rubber Company became very strong and scored an advance of 2 1-2 points on investment and speculative buying.

Gasoline Price Still Soaring

Gasoline is now 16 cents a gallon, delivered in steel barrels in wholesale lots. The advance of 1 cent was announced last week, the quotations for 200-gallon lots being raised to 21 cents.

The Standard Oil Company explains the advance on the same old grounds, namely, the pressure of demand, the limited character of supply and the rise in basic oils.

At the present level in wholesale lots, the price is higher than it was at retail last year at this time and is 7 1-2 cents above the level established prior to July, 1911, and 6 cents more than it was January 1 this year.

The automobile owner who can purchase in wholesale lots and who gets 8 miles to the gallon, can do a mile, as far as fuel is concerned, for 2 cents. If he is obliged to buy in lots of 200-gallons, the fuel cost per mile is 2 5-8 cents.

Otto Car to Be Sold Direct

PHILADELPHIA, July 22—The Otto car will be handled in future as far as sales are concerned, by the Otto Gas Engine Works, original manufacturers of the car, according to announcement. For the past year the line has been handled and sold by the Otto Mobile Company, of Mt. Holly, N. J., which went into the hands of receivers last week. The manufacturing company announces that it has no corporate connection with the embarrassed concern.

New Patent Bill Reported

WASHINGTON, D. C., July 20—Three distinct assaults upon the patent monopoly established by the United States Supreme Court in its recent decision on the Dick case are incorporated in a bill reported by the House committee on patents. A substitute bill to recodify the laws and meet the Supreme Court's ruling has been unanimously reported by the committee. The measure is much shorter than that originally drawn by Chairman Oldfield, of the patents committee, and is designed as an emergency measure for immediate consideration of Congress before adjournment.

The principal provisions to break up the patent monopoly under the Dick decision are: Prohibit purchase of patents by corporations designing to secure a monopoly upon patents in a general industrial line. Permit use of patented machines with materials not specified as a restriction upon their use. Amendment of the Sherman anti-trust law to punish patent monopolies.

The committee's bill will meet the Dick decision which held that any patentee could restrict the use of his article and also require use of any material or contrivance with it, by prohibiting purchase of patents. Another important provision is that persons who violate patent restrictions which limit the use of materials barred by the patentee cannot be sued for infringement of the patent.

General recodification of the patent laws, as recommended by Commissioner of Patents Moore, will not be attempted by the House patents committee until next fall.

Changes in Packard Representatives

DETROIT, MICH., July 22—The following changes have been made in the list of Packard dealers:

The name of the Eastern Motor Sales Company, Albany, has been changed to read the Dominant Motor Company.

Automobile Securities Quotations

The undertone in the market for automobile securities was strong but quiet during the past week. Transactions were not large in volume but for the first time in several weeks there was apparent a demand by odd-lot buyers. Those who are marketwise assert that buying of this character is a healthy sign. Among the big manufacturing companies there was an improvement in prices ranging from a small fraction to a point or more. General Motors was fairly active, the principal trades being made at a slight advance in the preferred and a material rise in the common issues. United States Motor Company was firm and rose fractionally. The tire stocks were steady as a rule but the movements were irregular. Comparative prices for July 23 of this and last year are:

U. S. Motors Does $2,000,000 in June

Sidney S. Meyers, attorney for the Motor and Accessory Manufacturers, has been elected a member of the creditors' committee now active in handling the affairs of the United States Motor Company finances. The move was made in order to maintain close touch between the banking creditors, who originally took action to grant the present 90-day extension of credit, and the merchandise creditors.

Reports of June sales by the United States Motor Company are to the effect that the business was in the neighborhood of $2,000,000 and so far in July the promise is for about as much more.

Market Changes for the Week

Midsummer conditions prevailed in the markets during the past week, the only changes of interest being a 2-cent rise in Kansas crude petroleum and a sharp flurry in tin during which it advanced 72 1-2 cents per 100 pounds.

Crude rubber has been firmer in the markets than it has at any time during the past 3 months and while trading this week has not been of large volume, holders have been able to work off some small lots of up-river fine at $1.18 a pound. Stocks in the hands of consumers are believed to be materially less than they were in June, which account for the strong undertone in the actual trading. The imports totaled 1,304 packages.

Mack to Enter New Field

Has Resigned Vice-Presidency of International Company and Will Build Motor Fire Apparatus

Universal Directors Cancel Flanders' Option and Will Continue Business on a Greatly Enlarged Scale

JOHN M. MACK, one of the founders of Mack Brothers, makers of the Mack line of automobile trucks, now included in the product of the International Motor Company, which has also the Hewitt and Saurer lines, has resigned his position as vice-president and has entered another phase of the manufacturing field.

Mr. Mack has been one of the prominent figures in the commercial car field for several years. It has been announced that he has formed a $600,000 corporation to manufacture automobile fire engines and automobiles at Allentown, Pa., and has secured control of the Webb Automobile Fire Engine Company, of St. Louis.

It is stated that the manufacturing operations will be transferred from St. Louis to Allentown and that the new company has secured the plant of the Allentown Machine & Foundry Company, to which will be added a brass-making plant now located in Philadelphia and controlled by Mr. Mack.

Universal Truck Co. to Expand

DETROIT, July 20—The option of the Universal Motor Truck Company's plant, which was held by W. E. Flanders and the Studebaker interests, was canceled by the directors of the Universal Company, at a meeting held Thursday. This leaves the truck concern entirely in the hands of the Schlitz brewery interests of Milwaukee, represented by Messrs. Uehline and Kopmeier, and F. K. Parke, of Detroit.

The capital stock of the company will be increased to $1,000,000, the interested parties having already added $500,000 to the capitalization to make possible the enlargement of the plant and the production of an entirely new truck proposition in addition to the present product. The new machine is a worm-drive affair, having a capacity of 1 ton, and has been in the course of its development for some time.

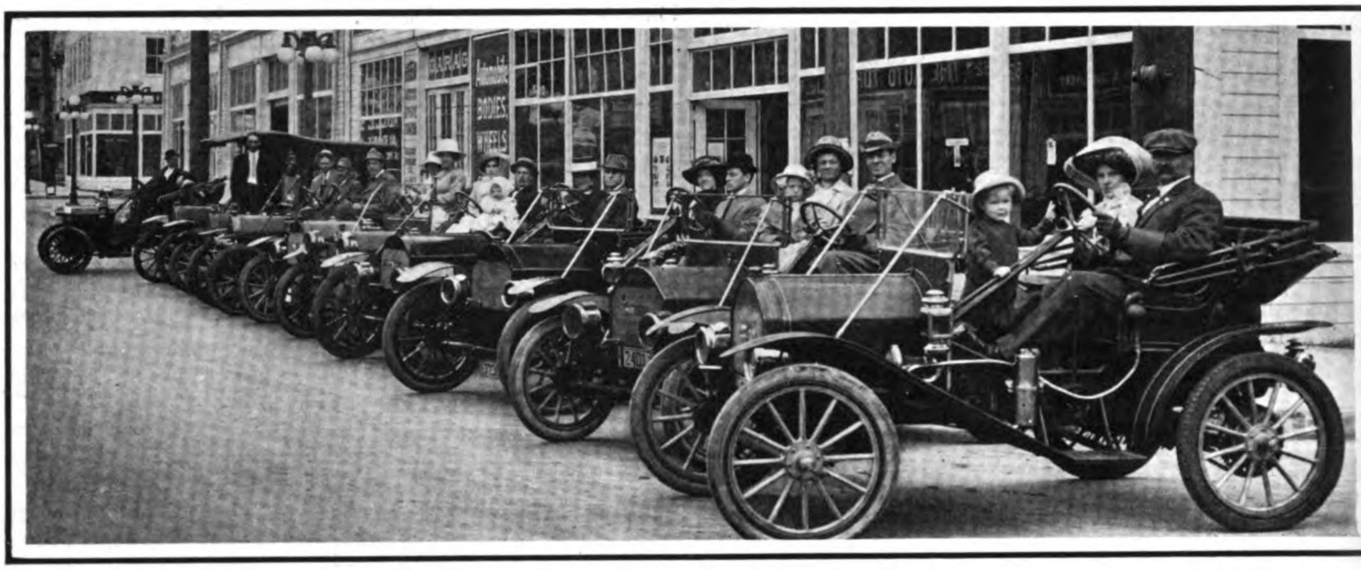
N.A.A.M. to Meet at Christmas Cove

The advance guard of the National Association of Automobile Manufacturers began to leave New York early this week for Christmas Cove, Me., where the regular meeting of the organization is scheduled for the last few days of this month. It is now expected that the meeting will be attended by about thirty-five members of the board and invited guests.

The program so far as it has been outlined does not contain anything of superlative interest to the public generally, but it is understood that the show question, the merger proposition which was acted upon at the recent meeting of the Automobile Board of Trade and other matters not upon the formal program will come up for discussion at least.

Writers Inspect Maxwell Factory

A group of New Yorkers representing automobile papers and magazines, accompanied by a photographer, made a trip of inspection on Monday through the Maxwell factory at Tarrytown, N. Y. The factory, which is located on the bank of the Hudson, was reached from New York by a fast motor boat chartered for the purpose. After a luncheon at Tarrytown, the factory was visited and the various departments inspected.



A few Brush owners in Portland, Ore., about to start on a basket picnic as guests of the local branch

GAS Traction Bought for $2,000,000—The Gas Traction Company, Minneapolis, Minn., has been bought into the $50,000,000 Emerson-Brantingham Company, of Rockford, Ill. The sale price was about $2,000,000.

New Service Station—The Taylor Automobile Company, 35 Orange street, Albany, N. Y., has established a service station in connection with its Locomobile agency.

Moves Into New Quarters—Burke & Aucock, agents for ignition apparatus, also doing repair work, have moved into larger quarters at 222 Columbus avenue, Boston, Mass.

Gardham Goes to Boston—Joseph Gardham, well known in the middle West as a driver, has gone to Boston, Mass.. to take charge of the Boston service department of the J. S. Harrington Company.

New Bedford Buys Abbott—The New Bedford, Mass., Board of Aldermen has approved an order for the purchase of an Abbott-Detroit car to be used by one of the heads of the municipal departments, the order being secured by the Boston agency.

Test Minneapolis Truck Law—License Inspector A. B. Gray has begun a test of the Minneapolis, Minn., ordinance requiring a tax of $1 for each motor truck used for hire. Several chauffeurs have been arrested on the charge of not having paid the tax and trials are set for future dates.

Vanguard Contract Not Renewed—The selling arrangement that exists between the Emil Grossman Company, of New York City, and the Vanguard Manufacturing Company, Joliet, Ill., for the sale of the Vanguard windshield will expire on August 1, 1912, and will not be renewed.

Changes to Motor Service—Frank Ware, superintendent of the Country Club, of Brookline, Mass., has disposed of the greater part of the horse-drawn equipment used to carry members to and from the club to the railroad and street car lines, putting three motor cars into commission for the same purpose.

Losey Paid Parting Tribute—Business interests of Indianapolis, Ind., paid a parting tribute to R. H. Losey, retiring manager of the sales branch of the Buick Motor Company, recently. Mr. Losey is to become general sales manager of the Republic Motor Company, with headquarters in New York.

Automobiles to the Rescue—The bursting of water pipes recently resulted in the entire water supply of the village of New Hartford, N. Y., being cut off. The Utica water company thereupon secured a number of automobile trucks, loaded them with milk cans of water and rushed to the relief of the villagers. The service was maintained till the break was repaired.

Valentine Goes to Rochester—John H. Valentine, head of the company bearing his name and which has had the agency for Chalmers cars in Syracuse, N. Y., has retired from the concern and is now connected with a Rochester, N. Y., company interested in the manufacture of motor trucks. Charles G. Hanna, inventor of the Hanna self-starter, is now at the head of the Valentine Company.

Form Self-Starter Company—Arrangements have been completed for the financing of a new self-starter company in New Orleans, La. The Thurber rotary self-starter, a recent invention by Edward J. Thurber and Jack Racklypt, of the Chalmers Motor Car Company of Louisiana, will be handled by a company to be capitalized at $200.000. The plant, which it is proposed to build, probably will be located in Detroit.

Ford's Minneapolis Branch—The Ford Motor Car Company has ordered plans in Minneapolis for its Northwestern branch at Fifth street and Fifth avenue to cost $250,000 to $300,000. The ground area will be 42,000 square feet. It has 340 feet of concrete in view. The building will be four stories at present, but the foundations will carry eight stories. The structure will be utilized for assembling, display, sales and shipping as well as service. The exterior will be brick with terra cotta trimmings.

Essenkay Opens Salesroom—The Essenkay Sales Company has opened a salesroom at 814 Seventeenth street, N. W., Washington, D. C., with W. G. Fairbank as manager.

Young Company Stops Business—The T. A. Young Company, which has had the agency for the R. C. H., Peerless and Marmon cars in Syracuse, N. Y., has gone out of business.

Utica After Light Law Violators—Utica, N. Y., is having trouble with automobile owners who are violating the law by failing to display tail lamps. Police in that city have been ordered to arrest violators of this ordinance.

Dinner for Rinker—Fred G. Rinker, retiring superintendent of the Indianapolis, Ind., plant of the Willys-Overland Company, was the guest of honor at a dinner given by thirty-five foremen of the plant at the Denison Hotel recently.

Reorganize Broad-Oak—The Broad-Oak Automobile Company, Columbus, O., which was recently sold out to a new set of owners, has been reorganized by the election of W. J. Miller, president; Robert R. Turner, vice-president, and R. M. Weaver, secretary-treasurer.

New Ottawa Tire Company—Another new firm is added to the business circle of Ottawa, Ont., being the Try-Me Tire Company, located at 266 Sparks street. This business was established through the enterprise of two well-known Ottawans, F. B. Carling and Eric H. McLachlin.

Cole Branch for Dallas—In preparation for the establishment of a branch house in Dallas, Tex., S. J. Kuqua, vice-president of the Cole Motor Company, is in Dallas for a few weeks. His branch will be the only one in Texas, and will be used as the distributing point of the South.

Trolley Scheme Falls Through—The International Trolley-Mobile Company, which was granted a franchise in Milford, Conn., some months ago for a trolley line through the town, has not been heard from lately and the terms of the franchise have not been lived up to so that it has expired.

Baltimore Agent to Move—Arrangements have been made whereby the Detroiter-Baltimore Company, Baltimore, Md., handling the Detroiter car in Maryland, Virginia and West Virginia, will occupy the property now used by the Lozier Sales Company. The Detroiter company will move into its new quarters August 1.

Cities and Towns Warned—The Maine Automobile Association has notified the selectmen of Scarboro and the city officials of South Portland that certain stretches of road within their jurisdiction are not in a safe condition for travel and that if any damage results to motorists or their machines while passing over the highways named suits for damages will be instituted.

Correction of R-C-H—In the July 4 issue of THE AUTOMOBILE it was stated, in the description of the new R-C-H, that the clutch is of the dry plate variety and that the gearbox is mounted amidship. This was an error, the clutch being of the leather-faced cone type and the gearbox being integral with the rear axle.

Service Station for Universal—Manager Charles Addison Malley, of the New England branch of the Universal truck, has leased the building 193 Pleasant street, formerly occupied by the Grabowsky truck company, as a service station and salesrooms for the Universal. H. L. Winters has joined him as sales manager.

Goodyear's Minneapolis Branch—Manager J. L. Jordan, of the Goodyear Tire & Rubber Company branch, in consultation with Western Sales Manager A. F. Osterloh, of Chicago, Ill., and Secretary G. M. Staddleman, of Akron, O., has selected a site for the new branch house in Minneapolis, Minn., and plans are being drawn.

Ford's Memphis Branch—Memphis, Tenn., is to be made the distributing point of the Ford Motor Car Company for a large territory in the South as soon as the new building of the company is erected. The Ford company has just closed a contract for a six-story, reinforced concrete building to go up in Union avenue at the Southern Railway Company's crossing. The new edifice is to cost $85,000.

Wants Name Changed—The Bowles Motor Car Company, Washington, D. C., agent for the Warren-Detroit, has made application to the court to change its name to the Warren Motor Sales Company. The company is to be reorganized and in future will be in part a factory branch of the Warren Motor Car Company, of Detroit, Mich. Charles Kloppmeyer will be the general manager.

Lippard-Stewart Officers Appointed—August Becker has been appointed president and E. J. Barcalo treasurer of the Lippard-Stewart Motor Car Company, Buffalo, N. Y., to succeed T. R. Lippard and R. G. Stewart, founders of the concern, who have withdrawn from the company to conduct the business of the Stewart Motor Corporation, recently incorporated to manufacture motor trucks of light capacity.

Changes in Baltimore—The United States Motor Company will discontinue the branch store in Baltimore, Md., now occupied by the Stoddard-Dayton Auto Company. H. S. Block, who has been manager of the branch, announces that he has arranged to purchase the Stoddard-Dayton company and will continue it as an agency. He will move to new quarters as the present building has been taken over by the branch of the Locomobile Company of America, T. W. Wilson, Jr., manager.

Seven Cartercars just purchased by the Milwaukee Fire Department for use of the battalion chiefs

Baker A No. 1, vest-pocket edition of Baker electric

Pope Director Resigns—Colgate Hoyt, of New York City, the banker, has resigned as a director of the Pope Manufacturing Company, Hartford, Conn.

Promotion for Brown—Sales Manager Benson, of the Studebaker Corporation, announces the promotion of A. H. Brown, manager of the firm's Spokane, Wash., branch, to be Northwestern sales manager for the company.

Devault Joins Federal—A. L. Devault, formerly with the United States Tire Company in Detroit, Mich., has joined the forces of the Federal Rubber Manufacturing Company as manager of its prospective Detroit branch.

Flatonia Club Elects Officers—The Flatonia Automobile Club, Flatonia, Tex., has elected the following officers: E. A. Arnim, president; F. W. Dusek, first vice-president; Hy Hurr, secretary; C. P. Thompson treasurer.

Hospital Buys Truck—The Boston, Mass., branch of the State Hospital has discarded its horse-drawn equipment and has installed one of the General Vehicle Company's electric machines to carry supplies to and from the hospital.

Land Company Establishes Club—The Bellevue Highlands Company, Gadsden, Ala., has taken over 253 acres of land on the top of Lookout Mountain for the purpose of establishing an amusement park and automobile club.

Smith Appointed Distributor—L. D. Smith has been appointed distributor for New York State of the O'Neil Tire Protector Company, which has established its state office and service station at 1056 Main street, Buffalo, N. Y.

Barnes Moon Publicity Manager—The rapid expansion of the business of the Moon Motor Car Company, St. Louis, Mo., has necessitated the appointment of a new advertising and publicity manager, Walter C. Barnes, of Springfield, Ill.

Miller Heads Cole Branch—F. P. Miller will have charge of the factory branch of the Cole Motor Car Company, Indianapolis, Ind., which is soon to be established in Detroit, Mich. Mr. Miller will be the Michigan distributor for Cole cars.

Crooks Alco City Sales Manager—Fred A. Crooks has been appointed city sales manager of the American Locomotive Works for New York City. Mr. Crooks, previous to his appointment, was connected with the New York sales department.

Van Wagner's Detroit Office—The E. B. Van Wagner Manufacturing Company, Syracuse, N. Y., has opened a sales office in Detroit, Mich., for handling the business in finished metal castings and die-cast bearings in the Middle West. Harry C. McCallum, Jr., will have charge of the Detroit office.

Bill to Manage Tudhope—Harry Bill, formerly general manager of the Metzger Motor Car Company, Detroit, Mich., has become general manager of the Tudhope Motor Car Company, Orillia, Ont., which makes the Everitt car in the Dominion. He takes with him Joseph Gardham as factory manager.

Syracuse Association Takes Joy-Ride—The members of the Syracuse Automobile Dealers' Association, Syracuse N. Y., took a number of their friends on their annual joy-ride recently, the destination being Trenton Falls. The route covered 150 miles and the run embraced some of the most picturesque scenery in the state.

Klaxet on the Market—The contest for the naming of the new Klaxon horn conducted by the Lovell-McConnell Manufacturing Company, Newark, N. J., has been brought to a close, the winning name being Klaxet. Several persons submitted this appellation, but H. I. Stengel, Spring Lake, N. J., was the first, entitling him to the award of $100.

Canadian Baker Company—The Baker Motor Vehicle Company of Canada, Ltd., was recently organized at a meeting in Walkerville, Ont. The following officers were elected: Jiram H. Walker, Walkerville, president; J. J. Coburn, Walkerville, secretary; W. C. H. Burnett, Detroit, treasurer; R. C. Norton, Cleveland, vice-president. It is the intention of this company to start operations immediately and it hopes to be able to build both pleasure and commercial electric vehicles in the near future. The company will manufacture the models now being made by the Baker Motor Vehicle Company, Cleveland, O.

Automobile Incorporations

AUTOMOBILES AND PARTS

Brooklyn, N. Y.—Dunham Auto Company; capital, $15,000; to deal in automobiles. Incorporators: Frank Dunham, Louis Carmadella, Charles L. Apfel.

Buffalo, N. Y.—Mason B. Hatch, Incorporated; capital, $20,000; to engage in the automobile business. Incorporators: Mason B. Hatch, Isabel W. Hatch, John M. Chipman.

Camden, N. J.—Auto Distributers, Ltd.; capital, $200,000; to conduct a general automobile business, comprising the manufacture and sale of motor cars. Incorporators: F. H. Hansell, I. C. Clow, John A. McPeak.

Chicago, Ill.—Triumph Motor Car Company; capital, $75,000; to manufacture automobiles. Incorporator: Gerald Christopher.

Indianapolis, Ind.—Brown Commercial Car Company; capital, $100,000; to manufacture freight automobiles. Incorporators: W. H. Brown, Carl H. Wallerich and others.

Memphis, Tenn.—Scott Motor Company; capital, $10,000; to engage in the automobile business. Incorporators: J. C. Scott, W. H. Hayler, C. L. Hunt.

Nashville, Tenn.—Hager Motor Car Company; capital, $5,000; to deal in automobiles. Incorporators: L. S. Hager, J. W. Hager, R. T. Pitman.

Nashville, Tenn.—Southwestern Motor Car Distributing Company; capital, $50,000; to conduct an automobile sales business. Incorporators: J. W. Bondurant, M. S. Bruce, G. C. Love, T. B. Crenshaw, H. J. Reiner, P. H. Phelan, Jr.

Newark, N. J.—Warwick Motors Company; capital, $125,000; to conduct an automobile engineering business. Incorportaors: James D. Necel, E. Orton Woodruff, Merton E. Hidden.

Newark, N. J.—W. S. Motor Truck Manufacturing Company; capital, $300,000; to manufacture automobile trucks. Incorporators: J. M. Woods, C. H. Tebbetts, L. T. Fetzer.

Owensboro, Ky.—Ames Motor Car Company; capital, $100,000; to manufacture automobiles. Incorporators: F. A. Ames, G. W. Yeoman, H. A. Robins.

St. Louis, Mo.—Superior Chicopee Motor Company; capital, $15,000; to manufacture and deal in automobiles. Incorporators: T. H. Burns, George C. Ward, Harry C. Carr.

Westfield, N. J.—Darby Motor Car Company; capital, $25,000; to engage in the manufacture of automobiles. Incorporators: Levy Douglas Darby, Harry C. Darby, Aaron B. Darby.

GARAGES AND ACCESSORIES

Cincinnati, O.—Acme Motor Delivery Company; capital, $15,000; to operate an express business. Incorporators: W. E. Minor, F. L. Allen S. P. Sutphin, Davis Wachmann, J. B. Minor.

News of the Garages

HAMPTON Beach Garage—F. L. Bristol, of Portsmouth, N. H., has opened a large garage at Hampton Beach, one of the big summer resorts of New Hampshire.

Holgate Garage Being Enlarged—W. Hustwiler & Sons, proprietors of the Holgate Auto Garage, Holgate, O., are constructing a large concrete addition to their building.

For 300-Foot Garage—The Colonial Motor Company, Baltimore, Md., is having plans prepared by the West Construction Company for a garage to be built in North avenue.

Watertown's First Garage—The F. H. Bronson building near the Taft School, at Watertown, Conn., has been fitted up by Charles Sherwood for a public garage, the first one opened in the town.

Buick Rochester Company Expands—The Rochester, N. Y., salesroom and garage of the Buick Motor Sales Company has been removed to 102 State street owing to increase of business.

Harrisburg Garage Adds Space—Schriver Bros., who have been conducting the Mt. Pleasant Garage on Thompson street, Harrisburg, Pa., have taken over the East End Automobile Company Garage.

Big Garage for Overland Branch—The Northwestern Overland Company, Minneapolis, Minn., is having plans drawn for a branch building to handle the Overland car, much larger than its present quarters.

Milford Garage Fire—Leaking gasoline set blazing by a lighted lantern used by workmen caused a loss of several thousand dollars and destroyed two motor cars in the garage of Nelson F. Huff, at Milford, Mass., last week.

Bristol, Conn., Garage—The Barker Automobile Company of Bristol, Conn., has given out the contracts for its new garage on Riverside avenue, which is to be a brick structure, one story high, with dimensions 100 by 60 feet.

Wedge Adds to Facilities—Plans have been prepared for a large addition to the sales agency and garage of the Wedge Company, at Sixth and Marietta streets, Zanesville, Ohio. The addition will be of brick 105 by 50 feet and two stories high.

South Carolina Garage—O. H. Wienges has purchased a site in St. Matthews, S. C., with a 90-foot frontage, and will erect a building. A portion of the structure will be equipped as a garage and occupied by the Wienges & Culler Automobile Company.

Etchell Garage Completed—The new garage of the Etchell Automobile Company at Five Points, Biddeford, Me., is now completed, giving the company a capacity for 25 cars. It is so located on two streets that cars may be driven directly through the building.

Plans for Orphans' Outing—Plans are being made by the motor Club of Harrisburg for the annual orphans' outing at Hershey Park on Friday, August 2. Last year the motor club inaugurated the annual orphans' day outing and took over 300 children to Hershey Park.

Springfield, Mass., Garage—One of the best garages in Springfield, Mass., has just been completed on Worthington street, in the center of the motor district, for R. A. McKee. It is two stories high, but the foundations are such that additional floors may be added from time to time.

Nashua Garage Company Incorporated—The City Garage Company has been incorporated at Nashua, N. H., by George L. Erb, who is president and treasurer, with John K. Martin as manager. The new company has purchased the garage and repair business of the City Carriage Company.

Transform Stable Into Garage—Columbus, O., is to have a large new garage to be located at the southwest corner of Third and Rich streets, in a large structure formerly used as stables for the Peruna Company. H. A. Sells and J. R. Clancy have taken a long-term lease on the property and the work of remodeling into an up-to-date garage is being pushed rapidly. The concern will be known as the Capitol Garage and Storage Company. It is expected to operate a taxicab business also. Mr. Sells will be in charge of the business and Mr. Clancy in charge of the mechanical end.

Automobile Incorporations

CLEVELAND, O.—King Valveless Auto Whistle Company; capital, $25,000; to manufacture automobile accessories of all kinds. Incorporators: Delroy Feffield, Orville C. Snyder, George H. Burrows, R. E. McMasters, C. J. Lowrie.

DETROIT, MICH.—Young Electric Company; capital, $50,000; to manufacture storage batteries. Incorporators: Philip Young, C. F. Tomlinson, G. W. Caverly, J. L. Marcero.

GRAFTON, W. VA.—Grafton Garage Company; to conduct a garage and repair business. Incorporators: Henry J. Pracht, H. D. Comerford, Albert Kunst, J. W. Yates, C. Lee Reynolds.

INDIANAPOLIS, IND.—Indianapolis Tire Company; capital, $30,000; to manufacture automobile tires. Incorporators: A. A. McKain, E. J. Holliday, A. C. Ayres.

INDIANAPOLIS, IND.—Jenney Electric Starter Company; capital, $300,000; to manufacture electric self-starters for automobiles and all other kinds of gas engines. Incorporators: Charles D. Jenney, William L. Taylor, Russell Willson.

JACKSON, MICH.—Jackson Rim Company; capital, $100,000; to manufacture automobile rims. Incorporators: Otis W. Mott, Winthrop Withington, Mark Merriman.

NEW BRUNSWICK, N. J.—Consolidated Auto Supply Stores; capital, $1,000,000, to deal in automobiles, supplies and accessories. Incorporators: B. F. Hardesty, A. W. Dennen, S. A. Ross.

KANSAS CITY, MO.—Palace Garage Company; capital, $5,000; to conduct a garage and repair shop. Incorporators: Elmo Sanders, G. Mass, Ida Dick.

NEW YORK CITY.—Essenkay Sales Company; capital, $100,000; to deal in a tire-filling material. Incorporators: Henry S. Young, Byron F. Abbott, William C. Oliver.

NEW YORK CITY.—Fifty-second Street Auto Repair Company; capital, $2,000; to engage in the repair business. Incorporators: Arthur Williams, Jr., Harold Matzinger, Anna H. Darrs.

NEW YORK CITY.—International Auto-Lamp Manufacturing Company; capital, $300,000; to manufacture automobile lamps and lighting system accessories. Incorporators: Hyman Agar, Nathan Agar, Thomas Cunningham.

NEW YORK CITY.—Far Rockaway Cab Company; capital, $25,000; to conduct an automobile taxicab business. Incorporators: Edwin Sommerich, Joseph L. Steinman, Arthur Behal.

PLYMOUTH, MASS.—Plymouth Garage & Machine Shop Company: capital, $10,000; to conduct a garage and repair shop business. Incorporators: Adoniram J. Smith, Ruth E. Kingan.

CHANGES OF CAPITAL

CHICAGO, ILL.—Automobile Owners' Association; capital, decreased from $100,000 to $50,000.

Motor Fire Apparatus

AKRON Adds to Fire Equipment—The Board of Control of Akron, O., has awarded the contract for a piece of motor-driven fire apparatus to the Webb Motor Fire Apparatus Company of Indiana at $8,200.

Camden, N. J., Energetic Buyer—The city of Camden, N. J., has bought three Studebaker roadsters equipped with chemical apparatus for its fire department. The three new vehicles are to constitute a flying squadron.

Add Another Life-Saving Car—Springfield, Mass., has added a second life-saving car to its fire department equipment, the order being filled by the Knox Company, of that city, that has built all the motor apparatus used by the Springfield fire department.

Chelsea Orders Fire Apparatus—At a recent meeting the Chelsea, Mass., Board of Aldermen appropriated $5,900 for the purchase of a combination motor chemical and hose wagon for the fire department and $3,600 for a combination automobile ambulance and patrol wagon for the police department.

Minneapolis Buys Fire Engine—The Minneapolis Fire Department Committee has recommended the purchase of a Nott Fire Engine Company pumping engine, made in Minneapolis. It is a motor engine also. The machine is said to have passed efficiency standards set by the city in the last few weeks' tests. The engine was contracted for in March at $6,500.

Albany Department Progresses Slowly—Fire Chief Bridgeford, of the Albany, N. Y., department, is planning to purchase within a few months several motor tractors similar to the one now in use in the Schenectady department. Chief Bridgeford intends to motorize the Albany department later on, but for the present he believes the tractors ought to increase materially the efficiency of Albany's fire system.

Car Economy Makes Firehouse Possible—When John Lennon, Son & Company submitted to the Niagara Falls, N. Y., Board of Fire Commissioners their bid of $9,180 for the construction of the new Highland avenue firehouse, gloom reigned among the fire officials, as it was too steep, but when Chief Utz discovered he had saved $225 on his automobile the story was different and the contract was awarded.

Niagara Falls Buys Combination Wagon—The new motor combination police patrol ambulance, costing $3,500, was delivered to the Niagara Falls, N. Y., police department last week. The machine is a Haynes, the chassis section being built at Kokomo, Ind., while the Henry Brunn Company, of Buffalo, made the body. The patrol will seat ten people, and with all accessories of an ambulance contains first aid paraphernalia.

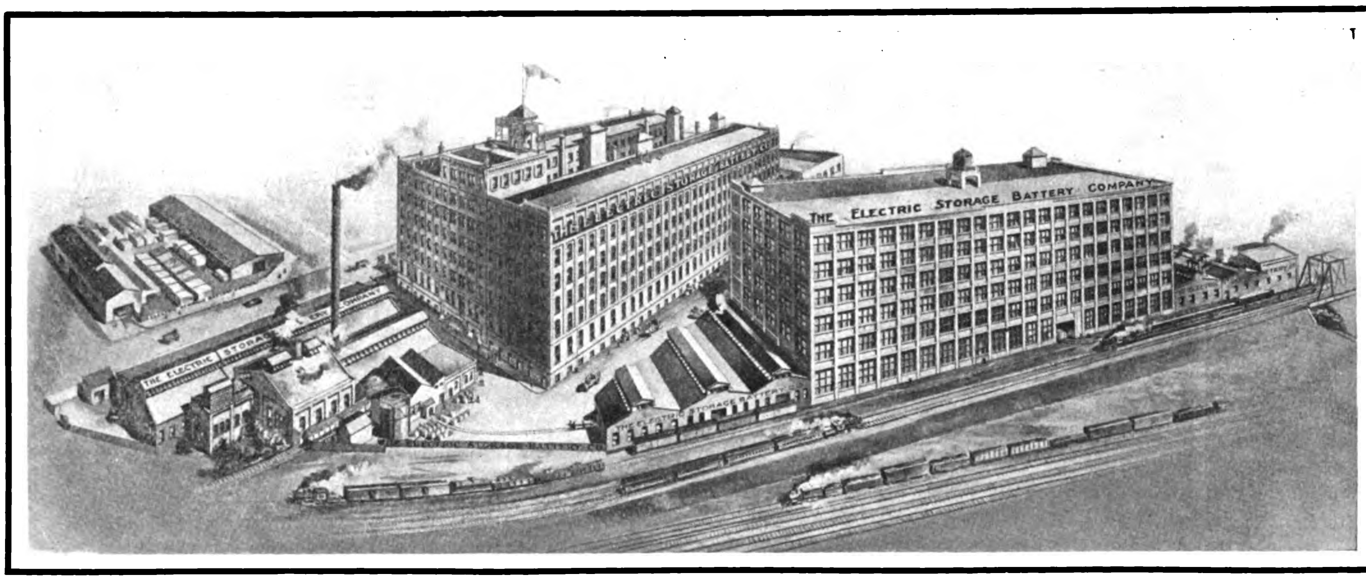
Davenport Motorizes Department—Convinced of the economy and efficiency of motor fire-fighting apparatus, Davenport, Iowa, has decided to dispense with the old-style horse-drawn apparatus and will purchase from the Seagrave Company, Columbus, O., an 80-horsepower motor tractor, which will be used in propelling the aerial trucks, an 80-horsepower combination hook, ladder and hose car and a special city service motor hose wagon.

St. Paul Fire Brigade News—The St. Paul salvage corps recently put in operation a salvage corps wagon furnished by the Woldref-Odell Motor Car Company, costing $6,250. It was made up of a body built by the Mitsch & Heck Wagon Company, of St. Paul, after plans by the superintendent of the corps, and Manager J. H. Segraves, of the motor company, and set on a Pierce-Arrow six chassis. The weight is 5,000 pounds. The car will carry five men, two tanks and fifty covers.

San Francisco to Motorize Department—The complete motorization of the San Francisco Fire Department at an early date will come as a result of the test made by the fire commissioners recently. It this test it was demonstrated conclusively that the motor-driven apparatus far outranked the horse-drawn apparatus in efficiency, and that in the case of ordinary fires the flames would often be extinguished by the motor apparatus before it would be possible for the horses and their heavy engines to arrive on the scene. Many of the smaller California Cities and towns have long boasted motor-driven apparatus. San Bernardino has used the motor wagons for several years and a number of the cities of Southern California early took this modern type of fire fighter.

Victor chemical and hose wagon now in use in Colorado City

Factory Miscellany



Bird's-eye view of the 14¼-acre plant of the Electric Storage Battery Company of Philadelphia

BIG Storage Battery Factory—The plant of the Electric Storage Battery Company, Philadelphia, has a floor-space of 14 1-4 acres, its entire capacity being devoted to the manufacture of storage batteries and accessory battery apparatus. The Exide battery made by the company is especially designed for use on gasoline cars, other types being made for electric car use. The building shown at the right of the above picture is a recent addition to the plant. It is 300 feet long, 115 feet wide and six stories high, with a one-story triangular extension 80 feet by 120 feet.

Reading Garage Changes Hands—H. F. Machmer and W. S. Degler have formed a partnership and will conduct the Riegel Garage.

Chalmers Wants to Build Now—The Chalmers Motor Company, Detroit, Mich., has approved plans for the erection of a new four-story factory building costing $75,000.

Timken Axle to Erect Factory.—A new factory is to be built for the Timken-Detroit Axle Company by Nettleton & Weaver, of the same city. The building is to cost $45,000.

New Penn Plant Starts Work—The new factory of the Penn Motor Car Company, New Castle, Pa., was put into full operation last week, work having been started in all departments so that car shipments can begin at an early date.

Willys-Gramm Plant Enlarging—The Lima, O., branch of the Willys-Gramm Motor Truck Company is to be enlarged in the near future. The plans for the addition and alterations have not yet been completed, but some definite announcement is expected within the next month.

New Pennsylvania Iron Center—The Eagan-Rogers Steel & Iron Company, Crum Lynne, Pa., representing a new industry for that section, has just started manufacturing operations. This company manufactures castings and small automobiles. The plant employs 200 men.

Moving Into Corbin Plant—P. & F. Corbin are now moving the machinery for their door-check department into the building formerly used to manufacture the Corbin motor cars at New Britain, Conn. The space thus vacated at the main plant will allow the manufacture of the company's other lines.

New Company in Maine—The Auto-Cart Company has been organized in Maine to build commercial vehicles at Hallowell, and it has the financial support of the leading business men of that city, also of Augusta, Gardiner and other Maine cities. Work will be commenced shortly on the vehicles.

Minneapolis Dealer Constructs Building—The Mitchell and Flanders electric representative in Minneapolis, F. E. Murphy Automobile Company, has had plans drawn for a building 100 by 137 feet, which is to be erected at Thirteenth street and Hennepin avenue. The building will be of brick and reinforced concrete and three stories high. Its cost will be $60,000.

Niagara Factory on the Way—Plans and specifications for the factory buildings of the Niagara Gasoline Motor Company, which concern has decided to locate at Dunkirk, N. Y., have been completed and work on the new structures will be started in a few days. The company decided to locate here if a $50,000 stock subscription could be raised by local citizens and the amount of $46,000 already has been raised.

New American Plant Completed—The American Motors Company, of Indianapolis, Ind., maker of the American Underslung cars, has just completed a three-story brick and steel addition to their plant No. 2. This new building is one of the handsomest and best lighted factory buildings in the city. It is of absolutely fireproof construction and is entirely inclosed with glass. The building is 85 by 120 feet, providing about 30,000 feet of floor-space. This will give about 100,000 feet of floor-space at plant No. 2.

English Reciprocating Valve-Grinding Tool; Adjustable and Lockable Valve Lifter; Sanitary Eye Protector; Battery Switch for Other Than Dual Magnetos; Spark-Plug With Visible Gap in Porcelain

Valve Repairing Tools

AN ingenious valve grinder devised in England is shown in Fig. 1. It is the product of Brown Brothers, Ltd., Great Eastern street, London, E. C. This machine is named the Warrow reciprocating valve grinder and is operated by the rotation of the handle H. The inner end of this handle or crank carries the part B which is shaped along almost half its circumference as a bevel gear. This gear, when rotated by the handle H, alternately engages the pinions P1 and P2 which are unit with the spindle S; the latter is held in place by the grip G. As the faces of the bevel pinions P1 and P2 are opposed, their alternate engagement with B imparts rotation in two alternate directions to the spindle which engages the valve, so that the latter is moved through half a revolution twice to every full turn of the handle H.

The second tool shown in Fig. 1 is the valve lifter of the Wright Wrench & Forging Company, Canton, O. This tool consists of two prongs P and P1, the latter being fulcrumed on the former at F. P1 carried a movable jaw J which may be locked along any point of the short arm of the prong. In operation, the bifurcated ends of the short arms of both prongs are placed around the valve stem and lifter stem as in Fig. 1, while the long arms, instead of being parallel, form an acute angle at A. By compressing the long arms till they are parallel the valve spring is compressed and the lifting tool may be locked in this position by means of the locking hook L holding the two long arms together. The valve lifter is made of drop-forged, case-hardened steel and made small and strong, so as to be adaptable to almost any type of valve.

Silk Gauze Lined Eye-Shield

The Leasure sanitary type of eye and nose protector, Fig. 2, is made by the Sanitary Sales Company, Bradford, Pa. It is a simple and light construction of one sheet of transparent material shaped to cover eyes and nose, which is fitted at its lower side with a piece of silk gauze, while the upper end partially covers the forehead. A smooth elastic band which is fastened around the head in the same way as ordinary goggles serves to attach the shield. The protector is designed to safeguard the eyes and the exposed parts of the face more thoroughly than is the case with ordinary goggles.

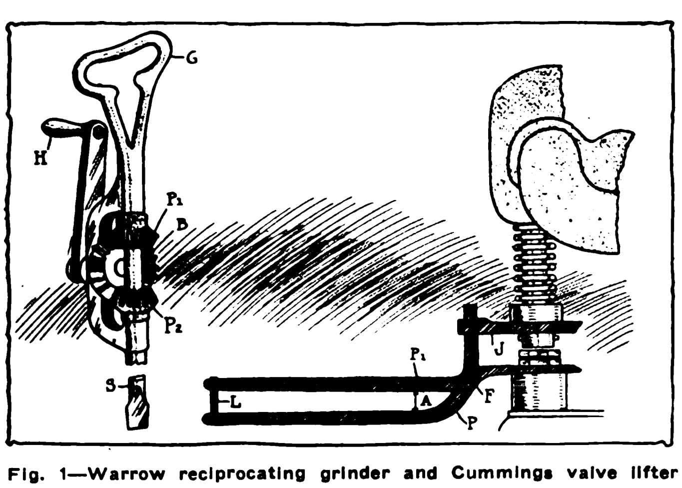


Fig. 1—Warrow reciprocating grinder and Cummings valve lifter

Foster Self-Starting Switch

A switch which permits the use of a self-starter requiring a battery for starting a motor equipped with other than a dual magneto is made by the Foster Appliances and Specialities Company, 146 West Fifty-sixth street, New York City. This switch is used in connection with an induction coil, both being illustrated in Fig. 5. The wiring system is shown in Fig. 4. The switch is of the kick-type appearance, but is preferably operated by hand. When the handle H is at either position marked M, the switch permits the magneto current to pass through it; but if the handle is in the central position B, a battery current is sent through the switch and thence to the distributer and the spark-plugs. When the motor is running, the switch handle is in either of the end positions M, and when, after rest, the motor is to be started on its acetylene self-starter, a quantity of acetylene is admitted to the cylinders, after which the handle is moved with moderate speed from one position M to the other. In this way the battery is put on for just long enough to produce one or two sparks in the cylinders, after which the magneto takes up the ignition work.

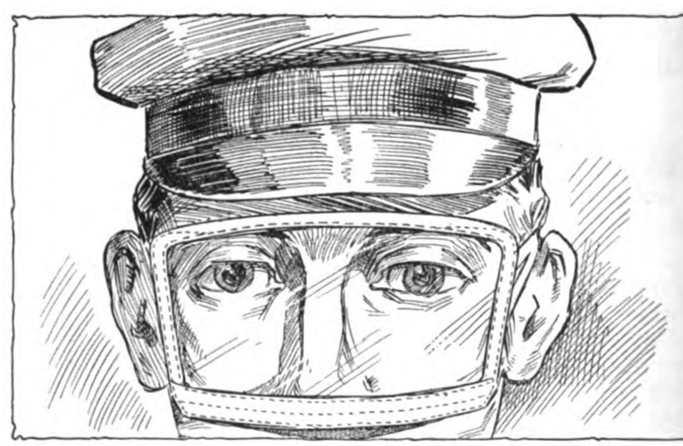

Fig. 2—Leasure light sanitary goggles and nose protector

Fig. 5 (III) shows the back of the switch with connecting pieces C1 and C2, which serve to connect the switch to the magnet. When this is done, the magneto attachment is put in place. To do this, the magneto bridge connecting the magneto terminals is removed, after which the contact nut on the collector is unscrewed and replaced by the attachment so that the horizontal contact (G in Fig. 4) points away from the magneto. Then the three terminal screws on the periphery of the switch casing are connected as follows: Looking on the back of the switch, the left-hand upper contact S3 is connected to the secondary lead coming from the coil, the right-hand upper contact S2 to the ground and the central contact S1 at the bottom of the switch to the primary lead from the coil.

The construction of the switch is shown in Fig. 5, (III) to (V), (III) being the back of the instrument which is made of an insulator substance having the appearance of red hard rubber. The inside of the insulator casing is seen at (V), the two ends of each contacts C1 and C2 projecting through the back, but being separated by the insulator substance on the inside. When the handle H is in either position M, the copper contact D (IV) connects the upper point of C1 to the lower point of C2 (V) or *vice versa*, so that the current flowing from the collector to the distributer of the magneto can pass through the switch. When the handle is put into the position B, the magneto current is interrupted, but the secondary current coming from the coil passes through the switch to the magneto attachment and thence to the distributer. The battery currents, primary and secondary, take the following paths: The battery primary current enters at S1, passes through the spring-fitted plunger P resting on it, then into the contact C3 driven into the insulation and grounded on the metal part M. From the casing the current flows through the spring S4 to contact S3 and thence to the ground, returning to the battery. The secondary current lead L from the induction coil is attached to the contact S3, and when the handle is in the central (battery) position, the contact C3 which is connected to S3 through the insulator casing contacts with pin P1 (IV). P1 is in contact with pin P2 which projects slightly out of the switch body K and rubs against the upper point of contact C1 which is connected to the magneto attachment.

The induction coil, Fig. 5 (I) is of the conventional type, the binding posts being Q1 and Q2. V is the vibrator, which is a steel spring held in place at one end by the screw W, while the other end carries the vibrator contact piece which makes intermittent contact with the bridge W1 of the binding post Q1. The high-tension wire is shown at L.

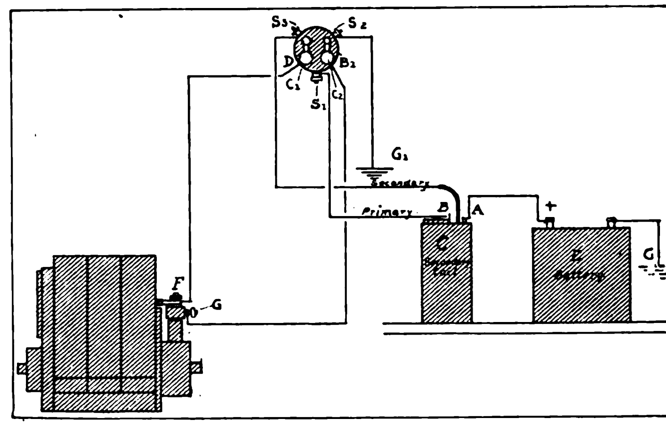

Fig. 4—Wiring diagram showing connections with Foster switch

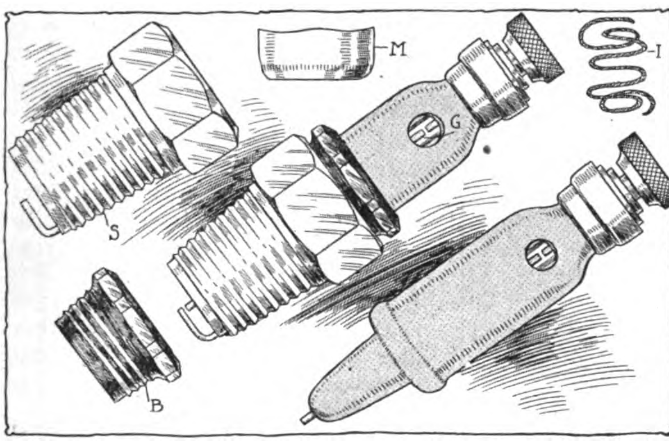

Fig. 3—Jeffery-Dewitt visible spark-plug and component parts

Jeffery-Dewitt Visible Plug

The new spark-plug of the Jeffery-Dewitt company, 500 Butler avenue, Detroit, Mich., is equipped with a visible spark gap in a circular opening of the porcelain, Fig. 3. This gap is formed by having the positive electrode shaped in two pieces, the upper one of which is rigidly secured to the terminal screw and is provided with a bolt thread near its upper end. This bolt is carried by a nut form of bearing, so that, by screwing the terminal screw in one direction or the other, the movable electrode portion is raised or lowered, increasing or decreasing the length of the visible spark gap G. The parts of the plug are shown in Fig. 3, S being the shell, B the bushing, I the insulating cord which separates it from the porcelain and M the metal cup which holds it in place thereon.

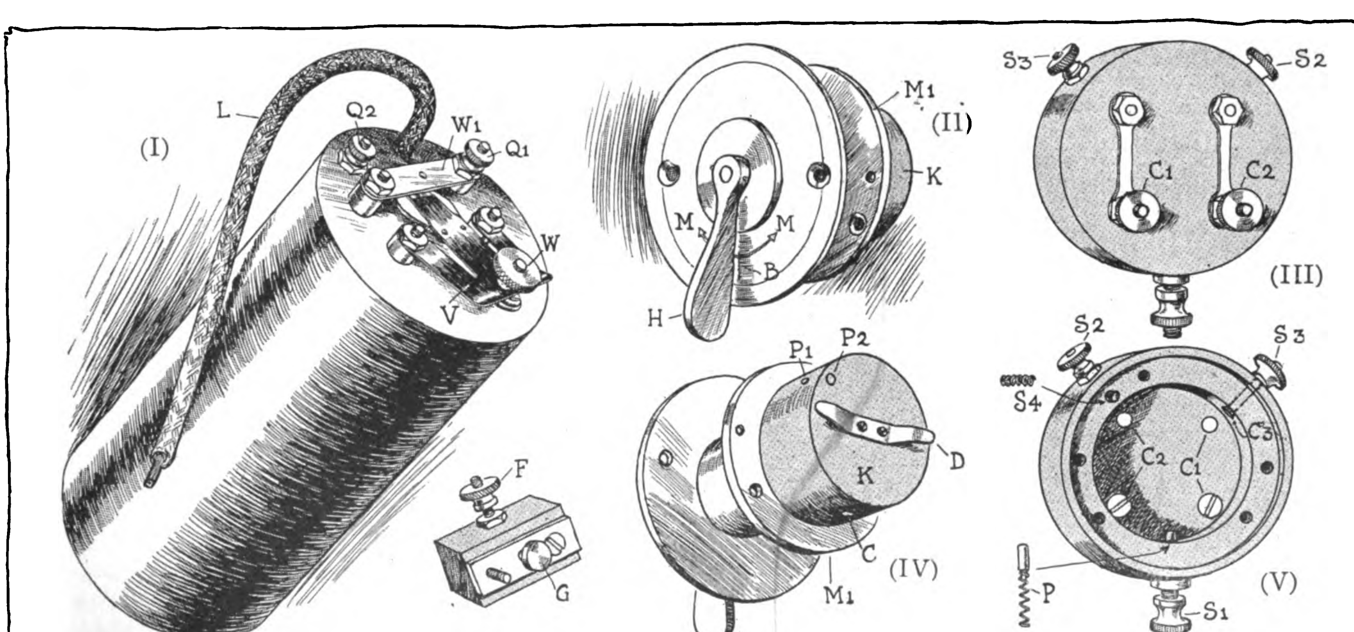

Fig. 5—Foster switch and parts: (I) Induction coil; (II) Front of switch, showing appearance on dash; (III) Switch body and moving contact; (IV) Back of switch casing with magneto contacts; (V) Inside and front of open switch casing

AUTOMOBILE Wheel—Operating on the elasticity of springs contained in spoke cylinders and a double rim. The wheel described in this patent consists of a hub H, Fig. 1, a series of spokes carried by the same and consisting of cylinders C and a rim composed of an outer portion O and an inner one I. The longitudinal axes of the cylinders are out of alignment with the wheel radii. In the cylinders, plungers P are positioned and spaced from the hub ends by coiled springs. The inner rim portion I is secured to the cylinder ends, and a series of bowed springs S is in place between inner and outer rims; to these springs the ends E of each alternate plunger stem is secured, while the other plunger stems are secured to the center of bowed spring T. The ends T are slidable on springs S.

No. 1,032,877—to James W. Calta, Platte, S. D. Granted July 16, 1912; filed December 29, 1911.

Lockable Monkey Wrench—The movable jaw is equipped with a pawl engaging a ratchet face on the shank.

This patent refers to a monkey wrench, Fig. 2, consisting of a shank S and two jaws J mounted on it, one of which is fixed and the other movable. A portion of the shank face is shaped as a ratchet which is adapted to be engaged by a pawl P mounted in the movable jaw. A pawl operating lever L serves to make the pawl prevent the movement of the jaw in one or the other direction.

No. 1,032,580—to Edward H. Anderson, Durham, Me. Granted July 16, 1912; filed March 6, 1912.

Automobile Bumper or Fender—In which shock is absorbed by springs coiled around arms which slide in guides.

The subject matter of this patent, a spring-operated bumper, is shown in Fig. 3. The bumper consists of a bumper bar B attached to arms A, which slide in guides G, springs S being coiled around the portion of A, which is outside of the guides G. The guides are adjustably secured to side bars S1 of the chasssis, being protected on clamps C

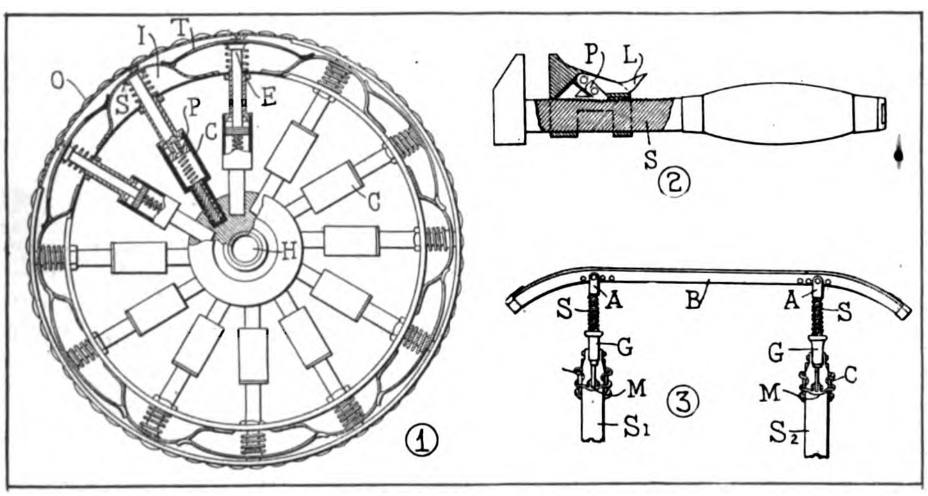

Fig. 1—Calta wheel. Fig. 2—Anderson monkey wrench. Fig. 3—McGregor bumper

No. 1,032,690—to Allan L. McGregor Chicago, Ill. Granted July 16, 1912; filed November 13, 1911.

Automobile Controlling Mechanism—Which provides for moving all fou road wheels in steering the car.

This patent describes a controllin mechanism for self-propelled vehicles composed of steering levers S1 and S. connected to steer front and rear roa wheels respectively. The steering gea is so constructed as to actuate the fron and rear steering. The constructio also including means for impartin movement to levers S1 before doing th same to S2.

No. 1,032,934—to Bennett J. Patrick Brookfield, Mo. Granted July 16, 1912 filed November 16, 1911.

Rotary Valve Construction—A rotary cone valve adaptable for connecting two sets of passageway:

An illustration of the valve referred to in this patent is see in Fig. 5. The construction includes a casing C which has tw sets of ports, P P and Q Q, opening in transverse planes. Th ports of one set are in vertical alignment with those of the othe A rotary closure R capable of connecting co-ordinate parts i mounted in the casing C.

No. 1,032,649—to John G. Bieniek, Chicago, Ill. Granted Jul 16, 1912; filed July 5, 1911.

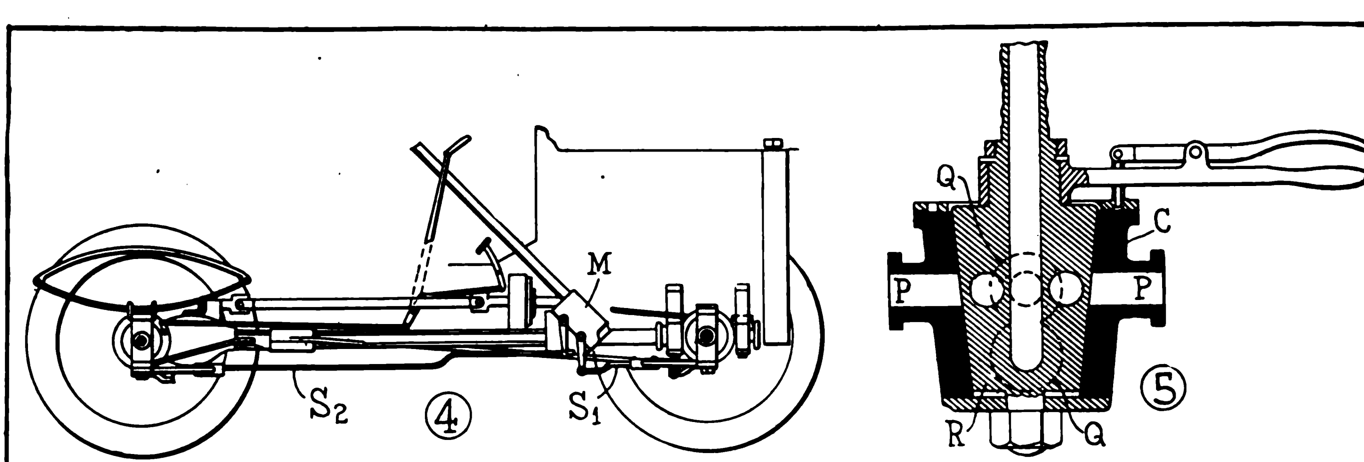

Fig. 4—Patrick automobile controlling mechanism. Fig. 5—Bieniek rotary valve

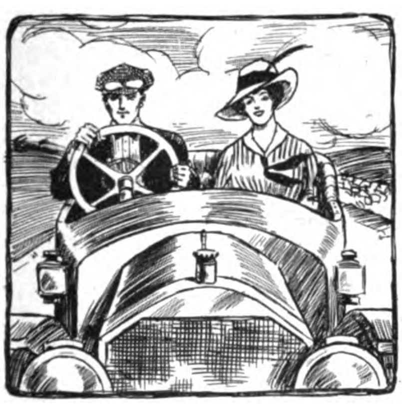
The AUTOMOBILE

Right or Left Control—Which?

Each System Has Its Advocates and Although the Former Has Been Considered Standard Practice for Years, the Latter Has Been Gaining Ground Rapidly—Advantages and Disadvantages of the Systems



Left-side control is making great strides in automobile engineering, having been introduced by a number of prominent designers. Many of the majority admit the utility of the left-side steer and the equally new though practical central arrangement of control levers. The divided opinions of engineering experts are contained in the following article.

PROMINENT among the tendencies in automobile design which have characterized the past 2 years is that of changing the steering wheel from the right side of the car to the left and the gearshift lever and emergency brake lever from the right side to the left or center. Today it is a much-discussed question as to which type of drive and control should be made standard, the number of companies changing from the right-side drive to the left type during the past season making the status of the right-side drive as a standard construction somewhat doubtful.

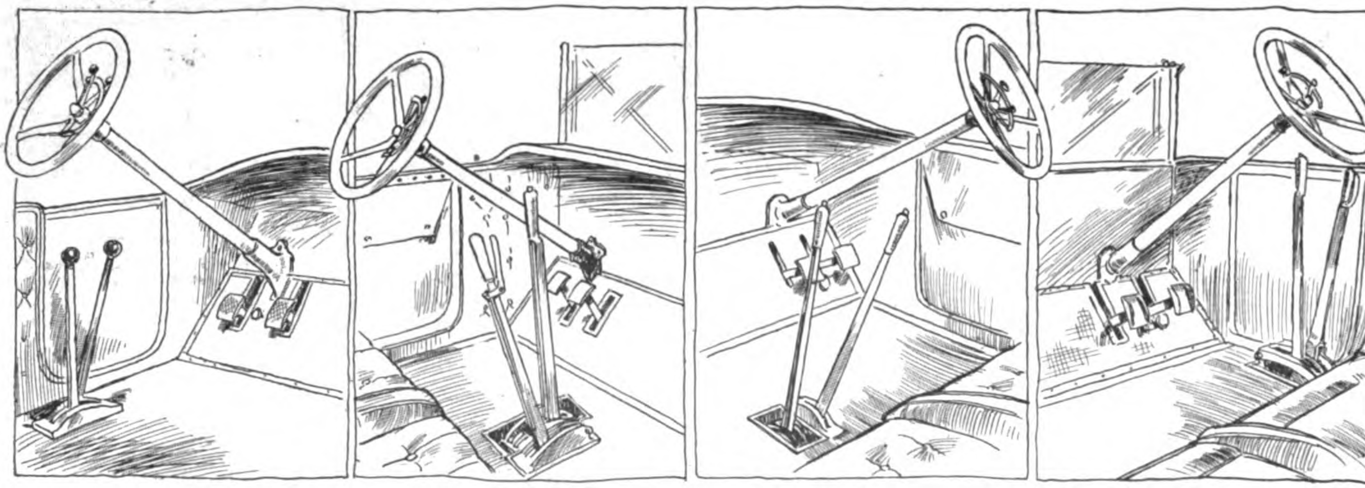
For some time the builders of the small cars have pinned their faith to the left-side drive, some of them placing the levers on the left side and others making the gear control central. The manufacturers of the larger, higher-priced machines have been more conservative, practically all of them adhering to the right-side drive, and most of them keeping the levers on the driver's right, until the announcement of their models for 1913 when it developed that several of them had been converted to the left-side drive with the levers on the left of the driver or located in the center of the floor-boards. The great majority, however, still continue to make the right-side drive their standard construction, although a number have settled the question to their own satisfaction by placing the levers in the center and making the situation of the steering wheel on the right or left optional with the customer.

It seems to be generally admitted that the left-side steer has all the advantage for city driving, while for country driving, the right-side steer is superior. As regards motor trucks, it is almost universally conceded that the left-side drive is better, as the greater part of their work is performed on the city streets.

Most of the right side adherents concede that the left type of drive is preferable for city driving, at least in congested sections where the traffic is fast and dense, but all maintain that this is a minor consideration as the long distances covered are over country roads where the right side drive has all the advantage. The believers in the left-side principle, however, claim superiority for that type not only in city driving, but also under all other conditions.

As to what is to be the standard construction on American-built cars, or whether the location of the steering wheel is to be made optional, time alone can determine, but, from all indications, the placing of the gearshift and emergency brake levers in the center will come to be generally adopted at some time not very far in the future.

Throughout the industry there seems to be a feeling that left-side drive is the coming standard, irrespective of the location of



Showing the four possible combinations of the steering wheel and gearshift and emergency brake levers in the driver's compartment of a modern automobile

the levers. But the general sentiment is that it is not yet time for such a change, that the public does not want it as yet and that the new state of affairs will come about gradually.

There are still a few adherents of the lever form of steering but these are mostly in the electric field, the wheel form of steer being practically the universal preference for gasoline cars.

The controlling features of the modern automobile, consisting of the steering wheel and, generally, a gearshift lever and an emergency brake lever, permit of four possible arrangements. These are: Steering wheel on the left side, with the control levers on the driver's left; steering wheel on the left, with the levers in the center, on the driver's right; wheel on the right, with levers in the center, to the left of the driver; and wheel on the right, with the levers on the right. The last type has the best claim to being the standard at the present time, 103 of the leading cars of the country using that type of drive and lever control as compared with seven makes which have become converts to the system in which both wheel and levers are at the left, seven which retain the right-side steer but combine it with a central lever location, and ten using the left drive.

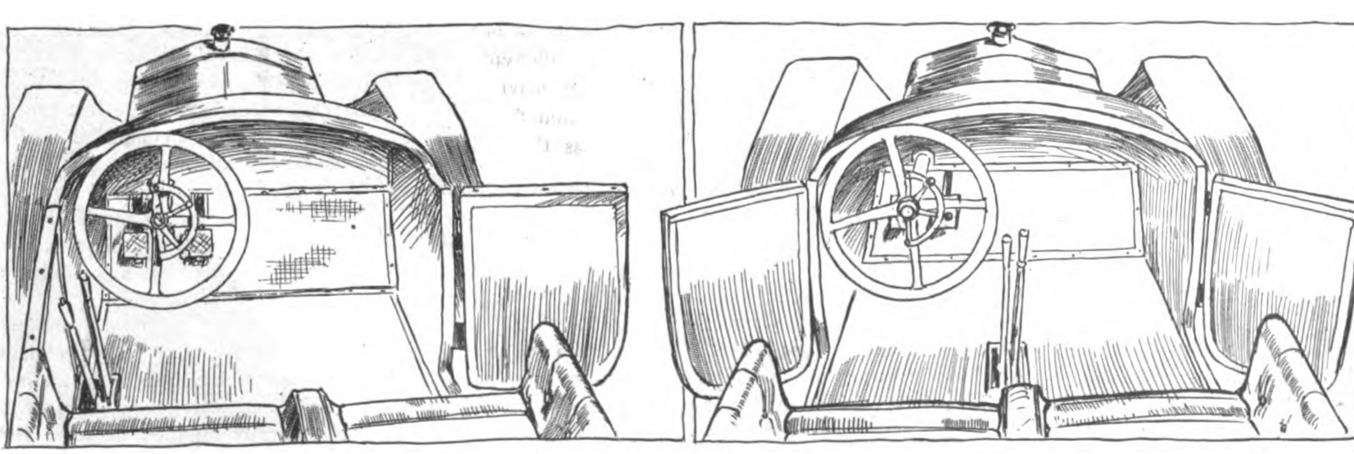
Advantages and Disadvantages

Each of the four possible arrangements has its advantages and disadvantages, as cited by its adherents. This being the case, it would naturally seem that the type to be adopted as standard should be that embodying the most important advantages and the least disadvantages. The main advantages and disadvantages of each type are as follows:

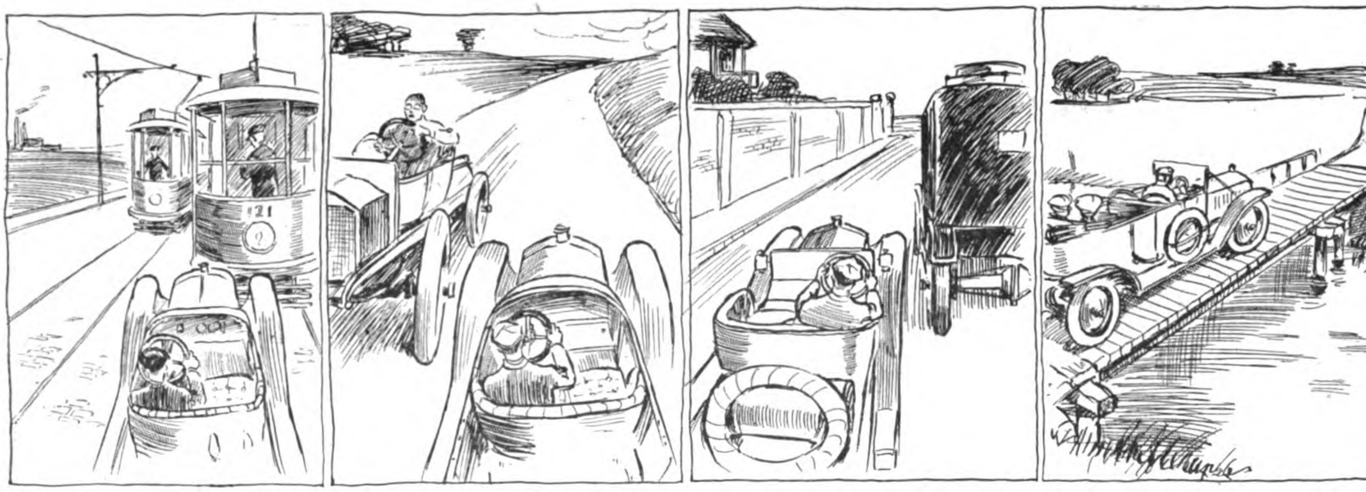
Steering wheel on the left side, with the control levers to the left of the driver:

Advantages: 1. Both front seats are accessible from the curb. 2. The driver can get out of the car quickly and easily to open the door and assist ladies to alight. 3. In passing vehicles going in the same direction, the driver is able to see any obstacle or other vehicle coming in the opposite direction sooner than with the steering wheel on the right side. Also, he can see how much room there is in which to pass a car on a narrow road. Similarly, in passing vehicles coming toward him, that is, in the opposite direction, he is able to see how much clearance there will be between the fenders of the two machines and thus to avert a possible accident. 4. The rules of the road necessitate keeping to the right, and the slant of the crowned roads throw the center of gravity of the car to the right. Putting the driver on the left overcomes this and there is a better weight distribution all around. 5. Driver has better view when turning to the left into a side street. 6. It is easier to signal when he is about to turn to the left. When turning to the right, no signal is necessary as the driver must keep to the right anyway.

Disadvantages: 1. The gear control and emergency brake levers are crowded close to the door and render exit from the left side of the car impossible, or at least difficult. 2. The driver has not a good view of overtaking traffic. 3. The driver has difficulty in estimating the minimum distance which he must keep between the car and a ditch to its right; also, in turning around a curb into a street to the right, he is liable to strike the curb stone of the pavement which is not in his view. 4. The fact that the traffic laws of Great Britain, its colonies and many other foreign countries prohibit driving at the right side of the road, forms the same disadvantage as the reverse law existing in the United States, thereby restraining the export business of



With the wheel and levers on the left, both seats are accessible from the right, but the levers are crowded against the door, while with the wheel on the left, but the levers in the center, there is free access to each seat, but the levers may be disturbed by the passenger



The two pictures on the left illustrate some of the advantages of left-side steer, while the other two indicate some of the good points of the right-side type

companies building left-hand drive cars. 5. The driver has to shift the levers with his left hand. Many, however, contend that this is not a disadvantage, as the left hand is just as efficient as the right for this purpose, it being merely a matter of growing accustomed to the different arrangement.

Steering wheel on the left side with the levers in the center, that is, to the right of the driver:

Advantages: 1. This type has all the advantages of the left-side steer as given above. 2. It has the additional advantage of permitting the use of two front doors, giving free access to each of the front seats from its side of the car. 3. It gets the levers out of too close proximity to the door. 4. By placing the gearshift lever directly over the gearbox, the material otherwise needed to transmit the motion from the quadrant at the side of the car to the box becomes superfluous, resulting in a saving thereof. This economy is paralleled by the saving in energy otherwise evidencing itself as friction or lost motion in the mechanism between gearshift lever and the speed-change set. 5. This system also retains the feature of right-hand shifting of the gears, with whatever advantages are bestowed upon it by custom and the familiarity imparted by years of right-hand shifting.

Disadvantages: 1. All disadvantages attaching to the left steer. 2. Driver must avoid levers in entering or leaving the car at the right side. 3. Passenger in the right front seat may disturb the levers. 4. The use of a single lap-robe in the front seats is rendered impracticable.

Steering wheel on the right, with the control levers in the center, to the driver's left.

Advantages: 1. Overtaking traffic can be observed. 2. In passing a vehicle coming in the opposite direction, the driver can see the edge of the ditch on the right of the road and knows how far he can turn out. 3. In passing a vehicle going in the same direction, he can see how much clearance there is between the fenders and thus is able to avoid accident. 4. In drawing up to a curb, he can see how much clearance there is between the front wheel and the curb. 5. The levers are not crowded against the door. 6. There is free access to each of the front seats from its side allowing the use of two fore-doors.

Disadvantages: All the disadvantages of right-side steer, which comprise: 1. The driver cannot see how much clearance there is between the fenders when passing a car going in the opposite direction. 2. He cannot see as well to make a turn to the left as with the left-side steer. 3. He cannot judge the amount of room between his car and the edge of the ditch, when passing a car going in the same direction, as well as with the left-side steer. 4. The use of a single lap-robe with any amount of comfort in the front seats is made practically impossible. 5. Left-hand gear-shifting. 6. Passenger in the other front seat may disturb the levers.

Steering wheel on the right, with control levers on the right.

For and Against Right Control

Advantages: 1. All the advantages of the right-side steer, as mentioned above. 2. As the present standard, everyone is accustomed to it. 3. Most people are right-handed, and may find it easier to shift the gears with that hand. 4. Clear access from the left side of the car.

Disadvantages: 1. All the disadvantages of the right steer, as already outlined. 2. The gear control and emergency brake

When the wheel is on the right, with the levers in the center, both seats are accessible, but the levers may be disturbed by the passenger, while with the wheel on the right and the levers on the right there is free access from the left, but the levers are crowded against the door

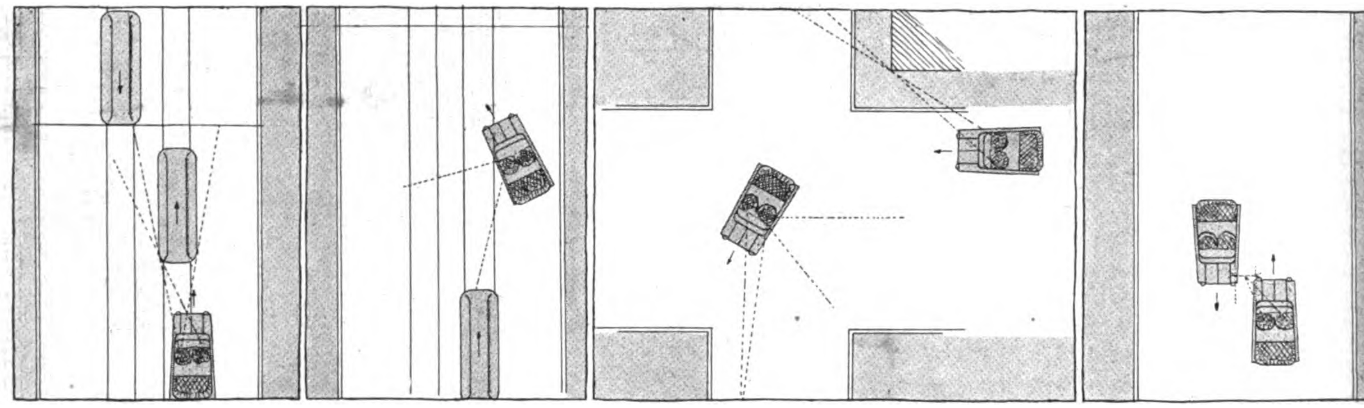


Diagram illustrating the ideas of William G. Wall, of the National Motor Vehicle Company, regarding the advantages of left-side drive

levers are crowded against the door. 3. Position of levers renders entrance and exit at the right side of the car a practical impossibility.

From glancing over the claims of the two systems to superiority, it appears that there is comparatively little advantage to be claimed for one type of steer over the other, as what is an advantage for the one is a disadvantage for the other. However, it seems illogical that we, in this country, should mount our steering wheels on the right when our rules of the road are the opposite of those in force in England, for example, where they consistently mount them on the right.

There is a distinct difference, however, in the question of the proper location of the control levers. The point at which they seem to give an excellent combination is in the center, irrespective of the location of the steering wheel, though placing them on the extreme left has the decided advantage of giving free access to both front seats from the curb.

In order to ascertain what the automobile engineers themselves thought of the question, THE AUTOMOBILE wrote to a number of the leading members of that fraternity, requesting them to give some of their views on the subject. Many highly interesting communications resulted, excerpts from several of which are given in this article.

Herreshoff Favors Left Drive

Many of the engineers stated their preference for the left-side type of steer, without being particular regarding the position of the control levers, although a few specified center levers. A number of them, however, maintained that the right-side steer is the best system, most of them preferring the central location for the levers. A few had no preference, declaring that one is as good as another and that it is all merely a matter of custom. There were some adherents of the left-side lever control and some of the right side. In other words, opinion seemed to be very much divided. Consideration for a similar division of opinion among the automobile-buying public found expression in the views of others who held that the location of the steering wheel should be made optional with the purchaser, while the control levers should be placed in the center.

C. F. Herreshoff, vice-president of the Herreshoff Motor Company, Detroit, Mich., is very emphatic against the right-side steer. After pointing out the advantages and disadvantages of each type, he states:

"I have driven in crowded streets in many of our American cities and I believe that there should be a law to prevent people driving a car with right-side drive, because those who drive cars with that type of drive are endangering the lives of others by getting mixed up in traffic. I have been in a great many tight places because of this and the driver has always stated that he could not see. It is a positive crime to allow big trucks to go along on our highways, and particularly in the cities, where traffic is congested, with the driver on the right side. The driver should always be at the extreme left where he can look over his shoulder to see the approaching traffic.

"We are selling cars all over the world and we cannot sell a left-side drive to foreigners, because the traffic rules are just the opposite to our own. Yet we have copied their right-side drive until our traffic has become of such importance that driving a car of this type is not only dangerous but needless."

Henry Souther, former president of the Society of Automobile Engineers, also speaks in favor of the left-side drive. He says:

"I see no particular objection to the left-side steer nor the left-side control, a few minutes' use making the left hand quite as expert as the right in gear-shifting.

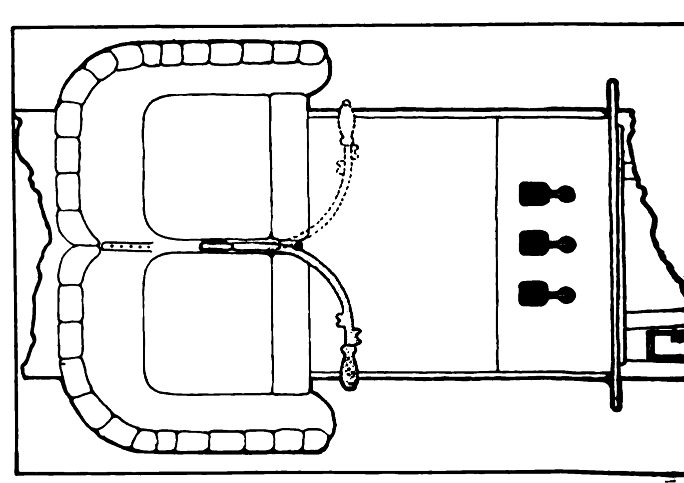
"Our present laws relating to stopping with the right side of the car on the right side of the street makes the left-side steer and, therefore, the right-side exit most desirable. Many times I have been obliged to put the women members of my family out into the slush or mud in the street because the traffic laws would not permit me to place the left side of the car against the curb. This alone is enough reason for the left-side steer."

William G. Wall, of the National Motor Vehicle Company, Indianapolis, Ind., points out the advantages in comfort and safety to be found in the left-side steer, declaring that:

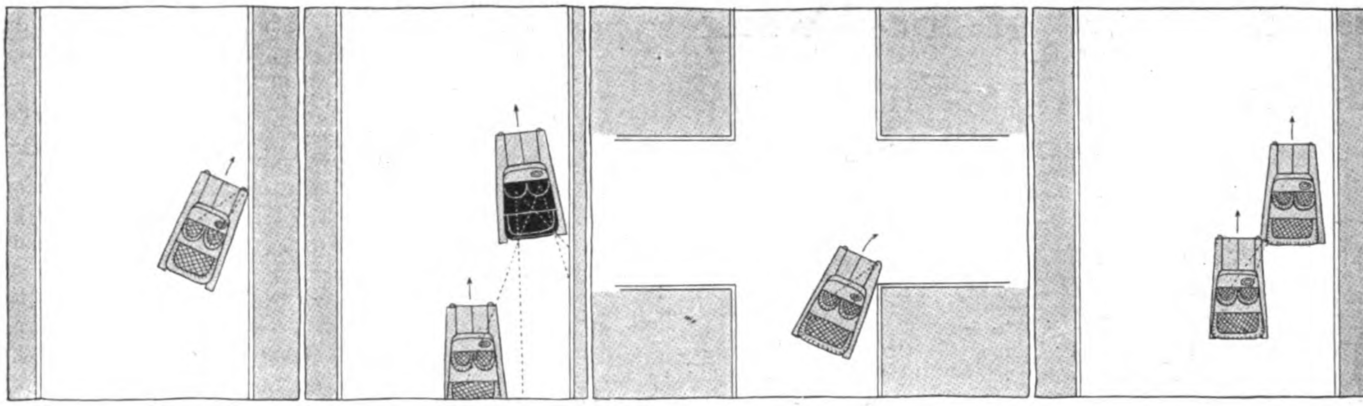
"About the only reason that can be given for retaining right-side drive is the cost to the manufacturers of changing their tools and jigs, which would be necessary in order to change to the left-side steer.

"The diagram (on page 212) shows the advantages of the left-side steer over the right-side type in respect to the view in traffic, in turning and in passing vehicles, especially street cars discharging passengers. The diagrams show the lines of vision from the two front seats and it is obvious which one has the advantage, not only in regard to traffic but also to looking down side streets and past buildings.

"Of course, the left-side lever location can be used with the left steering, as it is to a certain extent. Without question,



Plan view of the Duryea system, showing two positions of lever



Showing some of the points in favor of the right-side type of drive as emphasized by D. Fergusson, of the Pierce-Arrow Company

however, it is so much easier to operate any controlling apparatus with the right hand that it seems as if the center control naturally went with the left-side steer."

Frank Briscoe, vice-president of the United States Motor Company, makes the point that

"One objection to the left-side steer is that it will not do for export trade, as a left-side steer is just as wrong for England and her colonies as the right-side steer is for us, on account of their rules of the road being opposite from those in this country.

"There are some people who still prefer the right-side steer, for what reason I am not aware, and there is a possibility of our having to build cars with an option as to right- or left-side steer, which may produce another nuisance similar to the nuisance of the wide tread for southern trade."

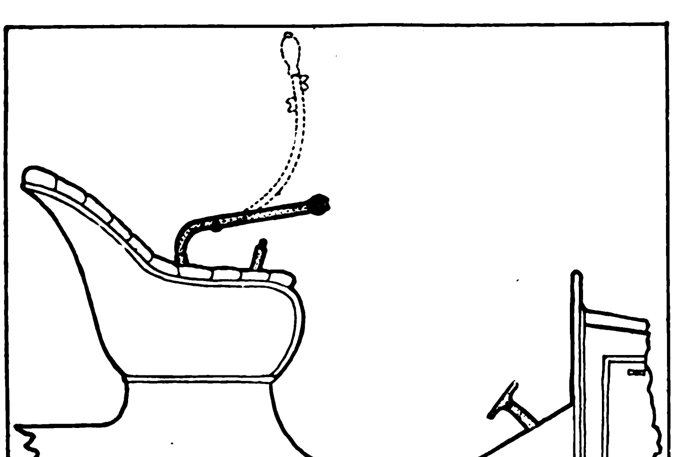
Elwood Haynes, the father of the Haynes car, expresses himself as in favor of the left-side steer without giving any preference as to the location of the levers. Chester S. Ricker, of the Henderson Motor Company, Indianapolis, Ind., H. J. Edwards, of the Edwards Motor Car Company, New York City, and J. F. Firestone, of the Columbus Buggy Company, Columbus, O., prefer the left-side steer in combination with the central position for the levers.

E. P. Batzell, however, stands forth as a defender of the right-side steer, but also prefers the levers in the center.

F. B. Stearns, of the F. B. Stearns Company, Cleveland, O., states:

"Personally, I do not believe there is a sale lost or made due to either right or left-side steer, although the left-side steer apparently has some theoretical advantages. Practically all of the high-grade cars are right-hand today, and all the users of these cars are accustomed to this type of drive."

D. Fergusson, of the Pierce-Arrow Motor Car Company, Buffalo, N. Y., after stating the various advantages of the right-side steer in respect to driving in both city and country, as shown in the diagram on page 213, declares that.



Steering and control arrangement used in the Duryea car

"The fact that right-side steer has become standard practice all over the world indicates that this is the natural position for driving. All horse-drawn vehicles are driven from this side and, as a matter of choice, it is therefore absolutely desirable to adhere to this method unless it can be shown to be wrong.

"The correct position of the change-speed and emergency brake levers is at the right of the driver. These are then out of the way of the adjoining passenger and robes can be used to much greater advantage."

Charles F. Barrett, of the Knox Automobile Company, Springfield, Mass., Harry C. Stutz, of the Ideal Motor Car Company, Indianapolis, Ind., E. E. Sweet, of the Cadillac Motor Car Company, Detroit, Mich., and Leigh B. Lynch, of the Studebaker Corporation, Detroit, Mich., esteem the matter one which should be optional with the purchaser, although all but Mr. Barrett state that they have no preference whatever in the matter.

Right and Left for Duryea

Charles E. Duryea, president of the Duryea Motor Company, Saginaw, Mich., is not troubled by the question of right or left steer on his cars as he has an arrangement designed to give both in combination with the placing of the levers in the center. He says:

"There is a very perceptible movement toward central-lever control with ambidextrous steer. Others who are using the conventional arrangements can better point out their good and bad points than we, who are using a more practical, more simple and, in our humble opinion, far superior device.

"We place the steering post at the center of the seat, both laterally and longitudinally, and permit the steering tiller to project forward and outward in front of the body of the operator. This arrangement gives a long lever and ample power to swing toward the wheels or hold them firmly. The tiller may be thrown up into a nearly vertical position out of the way in mounting or dismounting. It may also be thrown over to the opposite side and manipulated by the occupant of the other front seat."

According to the sentiments expressed by New York City automobile dealers, the left-hand drive is gaining in favor for metropolitan use. Some criticism of the left-drive system is made by a few concerns which sell cars upon which the option of left-hand construction is given and the companies and firms that handle right-drive cars can see little advantage in the opposite construction, but in the majority of cases the opinion is expressed that the left drive has distinct advantages.

Following is a brief outline of the views of a number of typical concerns along Broadway:

Cartercar—right-hand drive. Little inquiry for left drive.

Locomobile—optional. Twelve Berline-body cars equipped with left drive and center control were manufactured in January. One of these cars is still in stock, the sale of it having been canceled because of the left drive. The argument was made by the customer that the chauffeur could not open the

(Continued on page 241.)

Legal News of the Week

Ever-Ready Company Sues the Interstate Electrical Novelty for Infringement of Electric Battery Tester

August 12 Set for Sale of Atlas Plant—Mais Factory to Be Sold the Following Week

THE American Ever-Ready Company has entered suit in the United States District Court against the Interstate Electrical Novelty Company, charging infringement of Fuld's patent on a device for testing electric batteries. The device consists of a pair of holes drilled through the casing of a battery, opposite the battery terminals. They are so arranged that it is possible to test the battery without breaking the seal. The utility of the idea is that where batteries are kept in stock for considerable lengths of time and are subject to deterioration, it has been customary to open the containers to discover whether or not they were in salable condition before a sale. After the seals have been broken, there is no way in which to determine whether the battery has been used. Under the patent, the claim is made that while the battery can not be used without breaking the seals, a thorough test can be made as to its efficiency.

Cannot Sell Cut-Price Spark Plugs

Injunction was granted against the Auto Surplus Stock Syndicate and its president, forbidding them from violating the Mosler license to sell spark plugs. Albert Falck for the Mosler company showed the United States District Court the contention of the complainant that the syndicate was selling the plugs in suit at less than the scheduled price.

Law Violators Blame Manufacturers

BUFFALO, N. Y., July 30—One section of the Callan automobile law states that tail lamps should be installed on automobiles so as to cast their rays for a distance of at least 50 feet behind the machine and also should be placed so that the license number plate on the rear of the automobile can be seen plainly at all times. Buffalo motorists are openly violating this ordinance, explaining in many instances that suitable space for tail lights is not provided by many automobile manufacturers. However devices are on the market which allow placing the lights in the required position and, so Police Chief Regan declares, violators of the tail-light ordinance will be arrested promptly.

Victor Lamp Sues Knickerbocker

Alleging infringement of the Corcoran patent on a screw adjustment used in a certain type of vehicle lamp, the Victor Lamp Company has entered suit against the Knickerbocker Brass Goods Company, of New York, asking an injunction, accounting and damages in the United States District Court. The device is covered by patent number 980,493, issued in January, 1911, and transferred to the Victor company in June, 1912. Louis F. Perl is handling the matter for the complainant.

Atlas Plant to Be Sold August 12

INDIANAPOLIS, IND., July 29—In the superior court today, Judge Weir postponed the sale of the Atlas Engine Works to August 12. This was done with the consent of the receiver at the request of M. L. Thompson, representing a prospective bidder and the Baldwin Locomotive Works, Philadelphia, a heavy creditor.

Mr. Thompson said that the company which contemplates buying the Atlas plant has not yet been organized, but that the men who expect to go into it have ample funds to buy the property at a figure $25,000 higher than that offered by another prospective bidder from Detroit.

Fred C. Gardner, receiver of the Atlas company, has completed an inventory and his appraisement is $1,135,723.77. The inventory and appraisement is made up as follows: Cash on hand, accounts and similar items, $234,905.40; buildings, $518,056.50; grounds, $117,600; machinery, $351,845.13, and sprinkling and water system, $50,000.

The prospective bidder will have to agree to assume a bond issue of $1,050,000, pay another bond issue of $105,000 and pay mercantile accounts and the cost of the receivership proceedings amounting to about $80,000.

Ford Injunction to Be Argued

BUFFALO, N. Y., July 29—In United States district court, Wednesday afternoon, Judge John R. Hazel will hear arguments from officers of the International Automobile League of Buffalo who will try to show cause why the temporary injunction secured against that organization last week by the Ford Motor Car Company of Detroit, Mich., should not be made permanent.

In the bill of complaint filed by the Ford Motor Company officials it is alleged that for the past three years the International Automobile League of Buffalo and its officers have been engaged in various and continued attempts to infringe on patents and to break their contracts with the Ford people. It is alleged that the International Automobile League had advertised to sell Ford machines at less than the fixed price.

Taxicab Company in Difficulties

Petition has been filed by the American Taximeter Company to have the Kayton Taxicab and Garage Company declared bankrupt. The original motion for a receiver was denied, but Williams, Folsom & Strouse, attorneys for the petitioning creditor, announce that it will be renewed. The liabilities of the concern are estimated at $14,000 and the assets are placed nominally at $10,000 by the attorneys for the petitioner.

August 19 Set for Mais Sale

INDIANAPOLIS, IND., July 29—Judge Joseph Collier of the Superior Court has authorized Franklin Vonnegut, receiver for the Mais Motor Truck Company, to offer the concern's plant and property for sale on August 19. It is thought the plant will be bid on by some of the present stockholders and a new company organized to continue the business.

An appraisement of the property is under way and will soon be filed in court. Under the terms of sale, one-third cash must be paid at time of sale, one-third in twelve months and the remainder in eighteen months. Deferred payments are to bear 6 per cent. interest and be secured.

Shiland Leaves Buick for Havers

PORT HURON, MICH, July 29—Harry E. Shiland, formerly general sales manager of the Buick Motor Car Company, and for over twelve years an active factor in the manufacturing and sales of automobiles, has accepted a position as assistant general manager and director of sales of the Havers Motor Car Company, of Port Huron. There are rumors of other important announcements in connection with the Havers company.

A DECREE dissolving the Oliver Motor Car Company, bankrupt, was signed and filed by Judge Mandell on Friday, July 26, in the United States Circuit court. An order directing the sale of machinery has also been issued by the Judge.

General Motors' Thrift

Anticipates Floating Obligations and Will Deposit $1,000,000 on Account of October Bond Payment

Export Trade Figures Do Not Include Cars Taken Abroad by Owners for Pleasure

ANTICIPATING its floating obligations by paying them before the due dates, General Motors has liquidated its seasonable loans and it is announced by the management that $1,000,000 will be deposited with the Central Trust Company within a few days on account of the instalment of 6 per cent. bonds which is due October 1. The balance of the instalment is not due for 60 days.

General Motors floated $15,000,000 of gold notes 2 years ago this coming fall for the purpose of retiring floating obligations of the company and its subsidiaries and to furnish working capital. A part of this issue was so arranged that it had to be paid off in instalments. Last year the instalment was $1,500,000 and a similar amount will be retired this year. Next year, under the agreement, $2,000,000 will fall due and the same amount in 1914. The following year the remainder of the issue, amounting to $8,000,000 may be discharged at the option of the company or may be continued for 20 years. The company has the privilege of calling the bonds at any interest date on payment of 102 1-2 with accrued interest.

The action of the directors in setting aside such a sum as $1,000,000 for bond payment 60 days before it is due attracted much attention in the industry and was taken as a proof that the financial plans of the company have worked out nicely during the past season. The stock responded quickly to the report and advanced sharply to 77 1-2 and 34 respectively for preferred and common.

The fiscal year of the company ended July 31, but the annual report will probably require from 6 weeks to 2 months before ready for publication. It is understood that the company made new high marks all along the line.

Export Figures True Trade Index

WASHINGTON, D. C., July 29—O. P. Austin, chief, bureau of statistics, Department of Commerce and Labor, in commenting on automobile exports to foreign countries said that the figures as compiled are a true index to the business being done by American manufacturers with the people of other countries. Early in the automobile industry, Mr. Austin states, when figures on exports were prepared, they often included those machines sent abroad for pleasure purposes by the owners. In other words, these shipments were not kept separate from those sent purely for commercial purposes.

When it was discovered that such was the case instructions were given not to confuse the two and, as a result, the figures now submitted represent only those machines and parts shipped to be sold abroad, and indicate the increasing demand in other countries for the American-made product.

[Automobile Row was much interested in the report of the Bureau of Commerce and Labor covering the figures of foreign trade during the fiscal year ending June 30. The report showed that the total value of automobile exports including cars, parts and tires was about $28,000,000.

As compared with the showing of 1902, this is an increase of 2,800 per cent. in exports.

Last year the figures of the bureau showed exports of $20,000,000 but the manufacturing companies challenged them sharply and claimed that they should have been advanced at least $5,000,000.

The details of the figures for this year are as follows:

Exports	Value
Automobiles	$21,500,000
Parts	4,000,000
Tires	2,500,000
Total	$28,000,000

The figures show that the automobile industry is not only the most rapidly growing domestic line of manufacture, but also occupies that position in the foreign trade of the United States.

In former years automobiles shipped abroad for use by their American owners were included in the export totals, but for several years past such exportations have been separated from the amount of merchandise of this class that was shipped to foreign countries for sale.]

Michigan Buggy Adding to Plant

KALAMAZOO, MICH., July 29—An extensive addition to the automobile manufacturing department of the Michigan Buggy Company will be erected just north of the present plant. Ground already has been broken and it is expected the new portion of the company's plant will be ready for occupancy by September 15.

The building will be of reinforced concrete, 150 by 50 feet in dimensions and three stories in height. It will be fire-proof and equipped with an automatic sprinkler system. Nearly the entire north side of the building will be of glass. Sales and display rooms will occupy the first floor of the structure, while the second floor will be devoted to storage and the third floor to the painting and upholstering departments.

During the coming year the company expects to turn out 4,000 cars, for which orders already are being booked. This number will be an increase of 100 per cent. over the 1912 output.

Spayde Locates in Kalamazoo

KALAMAZOO, MICH., July 29—The Spayde Manufacturing company of Vicksburg, capitalized at $50,000, will locate in Kalamazoo within the next week. Articles of incorporation have been filed with the secretary of state and the Burtt building at Fulford and Clinton streets has been purchased. The company, which was organized at Vicksburg several years ago, manufactures automobile parts under patents granted to Herbert O. Spayde, the president. It recently outgrew its quarters at Vicksburg and decided to remove to this city. Following are the incorporators: Herbert O. Spayde, Henry E. Spayde, C. L. Major and Oliver Coleman. All reside at Vicksburg, Mich.

$450,000 Studebaker Stock Retired

Goldman, Sachs & Company, financial agents for the Studebaker Corporation, officially confirm the report that the Studebaker concern has ordered the retirement of $450,000 of the preferred issue floated several months ago. The reason for the retirement of the stock is that the company's business has been on such a large scale that there was no necessity of allowing this stock to remain outstanding.

U. S. Tire Co. Moves Offices

The general offices of the United States Tire Company have been moved to the new United States Rubber building, Broadway and 58th street, New York. This structure has recently been completed and will be utilized in future as the home of the United States Rubber Company and its subsidiary companies. The building is twenty stories high. The United States Tire Company will occupy the basement and sub-basement as a stock room; the ground floor for its New York branch and the fifteenth, sixteenth and seventeenth floors as general offices. The company has over 400 employees in its general offices.

Simms Co. Reorganized

C. G. Stoddard, of Edwards Motor Car Company, Assumes Active Management—Anderson Vice-President

Willys-Overland Capital Increase Approved by Ohio Secretary of State

THE reorganization of the Simms Magneto Company, Bloomfield, N. J., which was recently secured by the Asset Realization Company and the active management turned over to C. G. Stoddard of the Edwards Motor Car Company, has been completed. The original capital of the company was $1,000,000, all common stock. The new capital is $750,000, of which $500,000 is preferred stock and $250,000 common stock, all paid up. This new financing program has wiped out all the old debts of the company and provides a working capital of over $300,000, which, taken together with $100,000 worth of stock now on hand, puts the company in excellent shape to pursue its work.

The organization is working slowly at the start, having now over thirty men on the pay roll and adding more each week as the organization proceeds. R. C. Anderson, Racine, Wis., has been made general manager. He was formerly vice-president and general manager of the J. R. Case Company. At present two types of magnetos are being produced, SU4 and SU6, one for four-cylinder cars and the other for six-cylinder machines. The development of the two types of instruments for four and six-cylinder motors will be taken up in the near future. The company will have its complete line ready for the 1914 market. In the new organization C. G. Stoddard is president, A. A. Fisher, secretary and treasurer, and three additional directors are Campbell Carrington, vice-president of the Asset Realization Company; W. M. Kilbourn, vice-president National City Bank, New York, and Frederick Simms, London, England.

The company has secured sole American rights for the SU carbureter, the manufacture of which will be commenced in a few months and a complete line produced for the 1913 trade.

Willys Stock Increase Approved

TOLEDO, O., July 29—The increase in capital stock of the Willys-Overland Company, from $6,000,000 to $15,000,000, forecasted some time ago, was formally approved by the secretary of state at Columbus, Thursday. As a result in the increase in the organization's financial forces, extensive improvements will be made and these are already under way. The addition to the local factory will be made at an expense of several hundred thousand dollars. Incident to the expansion many new models will be placed on the market next year, among them smaller and cheaper cars.

Cordner Leaves American-Marion

E. Q. Cordner, sales manager of the American-Marion Sales Company of New York since that company was organized to handle the American and Marion lines, has resigned to accept the post of manager of agencies for the R. & L. Company, Eastern agents for the Garford line.

New Tire Chain Company Formed

TOLEDO, O., July 29—Toledo has a new industry directly allied with the automobile trade. The Walker Tire Chain Company is the name of the new concern which has a capital stock of $150,000. The company, originally the Walker Chain Mat Company, was organized last June and incorporated June 18. The concern will manufacture a patented anti-skid automobile and truck chain. The officers of the company are: President, H. F. Rohrman; vice-president Hugh Williams; treasurer, Maurice A. Carter; secretary, Charles A. Newman. Among the stockholders are John A. Dix, governor of New York; W. A. Huppuch, chairman of the public service commission of Hudson Falls, N. Y., and J. S. Parker, member of the general assembly of Salem, N. Y. The company was organized without debt and recently received its first order for 1,000 sets of chains. The plant will be temporarily located in the factories building when it is completed. The foundry work will be done at Bridgeport, Conn. and Brooklyn, N. Y., until the company builds its factory here, which it contemplates doing as soon as a suitable site can be secured. The assembly work will be done in Toledo. All of the officers are Toledo men except Vice-president Williams who resides in Granville, O.

Cole Agents Hold Conference

INDIANAPOLIS, MD., July 29—Several agents for the Cole were entertained at the factory of the Cole Motor Car Company in Indianapolis, during the week of July 22. The meeting was the regular quarterly conference of agents with the company. A dinner and conference were held at the Columbia Club at noon on July 25 and on the following day the agents, accompanied by J. J. Cole, president; C. P. Henderson, sales manager and H. C. Bradfield, manager of newspaper advertising, went to Detroit to inspect the Northway and Timken plants.

Market Changes for the Week

Few materials changed their prices during the past week despite the fact that a satisfactory degree of activity prevailed throughout the market. Tin was notable for its rise, the advance aggregating $1.30 per 100 pounds for the week. Steel, copper and lead remained at their old quotations, that of beam and channel steel being nominal during the latter half of the week. All told the tone of the steel market was firm, and whatever tendency of price changes that could be noticed was upward. The further fractional rise in the price of antimony may be ascribed, at least to some extent, to the use of this material in automobile bearings. The long-established price of cyanide of potash fell off slightly.

Up-river Para, which opened at $1.18 a pound, declined during the week in response to a fall of London prices and closed at $1.16. Petroleum, gasoline and lubricants remained at their former prices. The table shows the price fluctuations for the week.

Material	Wed.	Thurs.	Fri.	Sat.	Mon.	Tues.	Week's Change

The agents attending the meeting were William L. Colt and Harry S. Stratton, New York; E. J. and H. J. Habich, Boston; Gordon Cowie, Washington; E. A. Green and E. H. Baker, Buffalo; G. B. Schaefer and Frederick J. Decker, Rochester, N. Y.; C. M. Crim and G. H. Bronner, Utica, N. Y.; Jesse H. Wilbur, Troy, N. Y.; L. A. Perkins, Rutland, Vt.; F. Hagan, San Antonio, Texas and George Paddish, Brazil, South America.

Axle Makers Predict Record Year

FLINT, MICH., July 29—That the season of 1912-13 will be the most prosperous, in an automobile way, ever experienced by the city of Flint, is the prediction of General Manager H. H. Bassett, of the Weston-Mott company.

"Never before at this season of the year have we been so busy," he said. "This is supposed to be the dull season of the year and in previous summers there always have been slack periods. This summer, however, our customers have been pressing us to the limit. We have been busy every minute this year and from now on we will continue to be busier. The coming season will see us working our plant to capacity for the first time since factories 4 and 5 were erected."

In addition to its old business, the Weston-Mott company has secured the business of a large number of manufacturers who previously have had their axles made elsewhere. It has bid successfully for the business of many motor truck companies.

Another new branch is the manufacture of hubs, rims and axles for the makers of electric pleasure cars.

Automobile Securities Quotations

Automobile securities had a quiet week in the market, midsummer dullness being charged with the want of activity in trading. The whole list showed firmness, particularly the issues of the big accessory companies. The new Goodrich stocks moved up a peg on good business reports and the announcement that the initial quarterly dividend of 1 per cent. had been declared on the common. Studebaker preferred yielded a fraction despite the announced retirement of a large block of preferred stock and an optimistic statement as to business conditions by one of the executive officers. General Motors held firm on similar good reports. The affairs of the United States Motor Company are progressing favorably, according to Chairman Strong and the rehabilitation of the company is assuming a closer position.

Jewett Succeeds Lozier

Latter Retires from Presidency of Lozier Motor Company—New York Man for Vice-President

Company Will Soon Put on Market a Smaller Six at a Lower Price

DETROIT, MICH., July 30—Complete reorganization of the Lozier Motor Company was effected Monday at a meeting here of the board of directors. H. A. Lozier has resigned the presidency of the company and is succeeded by H. M. Jewett, president of the Paige-Detroit Motor Car Company. R. D. Fosdick, formerly commissioner of accounts of New York City, has been made vice-president and treasurer, while E. P. Earle and H. A. Kahler, prominent in New York's financial circles, have been added to the directors.

Coincident with the executive changes comes the announcement that the company will be in a position to make deliveries on a smaller six-cylinder car of lower price than the present 50 horsepower machine, which heretofore was the only model manufactured. This addition to the line will necessitate expansion of the plant, arrangements for which have already been made. The manufacture of the present Lozier model will be contained.

No change will be made in the policy of the company, and while Mr. Lozier has retired from the presidency he will not sever his connections with the company but will continue to take an active interest in its affairs. The remainder of the organization will remain intact. Mr. Jewett also retains the presidency of the Paige-Detroit concern. The addition of Messrs. Kahler and Earle gives the company strong backing in the East.

Wyeth Car Makes Initial Bow

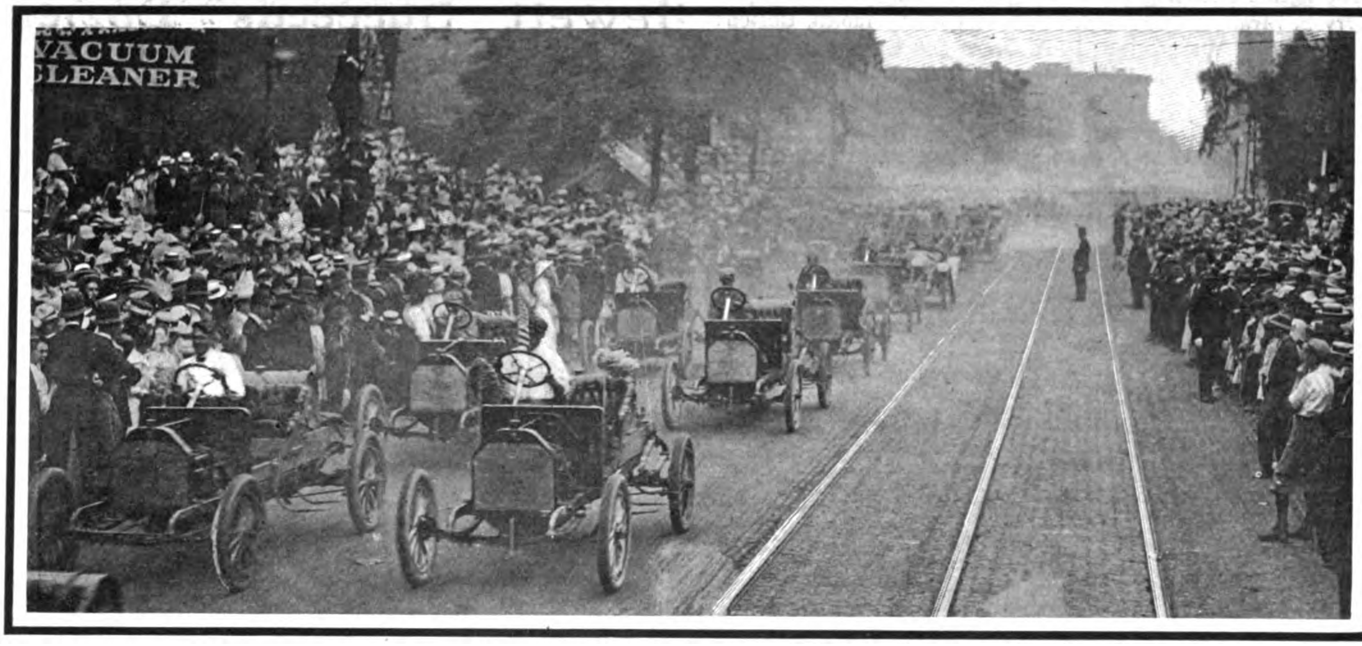
BOSTON, MASS., July 29—The Wyeth is the latest addition to the motor industry and it has been put on exhibition at Boston. It is made in Waltham, Mass., and comprises a runabout, also a delivery wagon. The runabout sells for $450, the open delivery wagon $500 and the closed delivery vehicle $550. The motor is a single cylinder 4 1-4 x 6 in., S.A.E. rating 7.2 horsepower, developing 13 horsepower on a brake test at 1200 revolutions. The ignition is two sets of batteries, Bemus timer, high grade coil. The lubrication is splash and pressure feed system, sight regulation on the dash. The oil tank is under the hood. The motor is water cooled with thermo syphon system. The transmission is planetary, two speeds forward and reverse, running in oil and double cased. The wheelbase is 90 inches.

Some of the features original with the car and for which the makers have patents comprise the body suspension, the body being hung between side members, hinged at front end and independently supported on full-elliptic springs at rear; also the straight line drive without universal joints; and a muffler guaranteed silent and free from back pressure. The car weighs 1,000 pounds.

G. & A. Increases Capitalization

Increasing its capitalization from $25,000 to $100,000, revising its official roster and preparing to enter its new factory at Long Island City, the G. and A. Carburetor Company is about ready to cut a bigger figure in the accessory industry of the automobile business. The increase in capital has just been announced, although it was effective July 1. C. Stanley Mitchell has been elected vice-president of the corporation.

Several mechanical innovations and a new type of auxiliary carbureter are under consideration by the company.



Some of the E-M-F test cars which participated in the Cadillaqua pageant in Detroit

Cadillaqua Fête a Success

Automobile Industry of Detroit Plays a Big Part in the Week's Festivities—Monster Parade

Commercial Vehicles Featured in the the Industrial Pageant—Antiques and Modern Racing Cars in Line

DETROIT, MICH., July 27—Detroit, the first city of the land so far as automobiles are concerned, saw the final feature of its great birthday week yesterday. The success of Cadillaqua, as it was called on the suggestion of W. E. Blaine, who received from the Cadillaqua association a Flanders 20 touring car as reward for his originality, was due in no little measure to the part played by the automobile and the giant motor car industries of the city.

The parade, which was perhaps the largest gathering of automobiles yet seen by any people of any time, required an hour and 45 minutes to pass the reviewing stand on Woodward avenue. The giant column was three abreast in many places and was more than 2 miles in length. The total distance paraded was 5 miles, the start being made at the corner of Grand Boulevard and Woodward avenue. The column wended its way down the latter thoroughfare until Jefferson avenue was reached, where it turned east and continued to East Boulevard, and there disbanded. Throughout the entire 5-mile course, the streets were deep lined with a record-breaking throng of people.

There were many beautifully and gaily decorated automobiles in the long column, but no one contingent was so consistently attractive as that of the suffragettes, the half dozen cars which made up their part of the procession being a profusion of yellow, intermingled with the blue and gold Cadillaqua colors. There was a countless array of "Votes for Women" banners displayed. To further show their independent spirit, several of the ladies of this section of the affair piloted their own cars.

In point of number of cars entered, the Studebaker Corporation, maker of E-M-F's and Flanders 20's, easily surpassed all others, although the Cadillac, Hudson, Overland, Krit, Jackson, Detroiter, Paige, Warren, Abbott, R-C-H and Hupmobile entries were not far behind. The novel feature of the E-M-F gathering was the test cars which were in line, about thirty being seen. Following these were a number of both E-M-F's and Flanders. The Detroiter contingent led the procession.

The Wolverine Automobile Club was the promoter and director of the automobile parade and it offered prizes to the persons or concerns having the best decorated cars. The first prize was given to an electric which was most beautifully decorated in white, paper flowers completely covering its sides. A giant butterfly was fastened to its front and appeared to be pulling the machine under the direction of a huge doll fastened above the seat and in whose hands two long white ribbons were fixed as reins. The two ladies who rode in the car were also dressed in white to further set off the pleasing effect of the whole.

A unique feature was the appearance of several Packard and Cadillac veterans in the line. The oldest Packard, which dates back to 1899, preceded the youngest Packard, which had been turned out of the factory but a few minutes before the start of the parade. Cadillac veterans of all ages were seen, the oldest model coming first and being followed in succession by later types until at the last the 1912 product appeared. The oldest Grinnell electric was also in line. Lozier paraded its Vanderbilt Cup winning car of last year.

Factories Represented in Pageant

The industrial pageant which took place on Wednesday evening also had a large representation among Detroit automobile factories. The Packard concern entered a pure-white and gold-trimmed float, which was among the prize winners of this event. It consisted of a phaeton model finished all in white and upholstered in white velvet in which were seated several persons also in white.

A costly float was entered by the Chalmers company, which was composed of one of the concern's latest models mounted on top of a platform, the sides of which represented the huge factory in papier-mâché. Many lights iluminated the windows of the miniature plant.

The Flanders electric and the United States Tire floats were also very attractive and represented a large amount of work. The latter carried a great map of the United States. The Studebaker float was made doubly attractive by its setting, it being partly concealed by a bank of clouds, and surrounded by a number of young women. The Cadillac float was of spotless white. A Cadillac car was placed on a raised platform and was drawn by four white horses. The Warren-Detroit float showed a number of workmen in the act of assembling a chassis.

Knight Motor in Europe

L. B. Kilbourne, Partner of Sleeve-Valve Inventor, Reports Rapid Growth of Their Business Abroad

Why Sigma-Knight Did Not Start in Grand Prix—Hard Luck Prevented Targa Florio Win

CHICAGO, July 27—L. B. Kilbourne, partner of Charles Y. Knight, inventor of the sleeve-valve motor, is back in Chicago after a visit in Europe, some of which time was given up to attendance at the trial of the suit of the English Argyll company, a decision in which is expected shortly.

"Our business in Europe is growing in leaps and bounds," says Mr. Kilbourne. "The Daimler company, which made 2,600 Knight-engined cars for 1912, has made its plans for 3,000 for 1913. In addition it is selling many engines to others in that country. The Sidderley-Deasey already has used 450, fitting to both fours and sixes, while a considerable engine business is done by Daimler in Germany, France and America. The Daimlers are making more six-cylinder cars than fours. In Belgium the Minerva people are erecting new factories and planning to increase their output from 1,200 to 2,000. Panhard of France has added a Knight six and also is making a small four, making three models of Knights in all, while the Mercedes company in Germany has brought out two new Knight models to go with the one it originally had. One of these is 4 3-4 by 5.

"The Sigma-Knight builders in Switzerland are at the present time reorganizing their company with the idea of broadening out. They started out with only the Switzerland rights and found they were handicapped by being so limited. They saw the opportunity to get the Italian rights and they have taken an option on this privilege, which will be taken up when the company is reorganized. One of those interested in the Switzerland company is young Levassor of France. The Sigma-Knight is made in two models, one 18 horsepower and the other 25 1-2 and the car is a success.

"It was because of this reorganization that the Sigma did not start in the French grand prix. It is not generally known, though, that it did run in the Targa Florio in Sicily. An agent bought the car himself and entered it and it was only because of hard luck that he did not win. He writes that at the end of 200 miles he was 35 minutes ahead, when he lost his gasoline tank. He had to make a new tank and wait 2 hours for more gasoline, yet he finished tenth."

A cablegram received on Wednesday from London by Mr. Kilbourne conveys the information that the suit against the Argyll company has been decided adversely to the Knight interests, but that an appeal has been taken, with strong hopes of ultimately winning. The decision was based upon the legality of the amendment made in 1908 to the first claim of Knight in 1905. The English judge hearing the case refused to read the claim as amended on the ground that the scope of the patent was widened thereby, which is denied by the Knight interests. It is stated that former practice always considered an amendment through the comptroller as final. The judge held that the Knight patent is not invalidated, but holds that it covers only the reciprocating motion. Leave was given to amend the error in the specification.

Motor Fire Apparatus on Show

On Wednesday, October 2, there will open in Madison Square Garden, New York City, to continue till Saturday evening, October 12, an exposition of modern apparatus for the prevention and extinguishment of fires. The exhibition is to be held in conjunction with an international conference of fire-department officials representing many of the larger cities of the world.

Many manufacturers of motor fire apparatus will be represented in the exhibition, which will include fireproof building construction, fire alarm systems, automatic sprinklers, fire escapes, and, in fact, every conceivable device and manufacture in the fields of fire prevention and extinguishment. Daily conferences will be held, where architects, builders, engineers, insurance men, and fire-department officials from all over the world will read and discuss papers on pertinent subjects.

Mayors of many of the principal cities of the United States have appointed their fire chiefs or commissioners as delegates to the conference and exposition.

Hospitals Rushed To the Injured

Surgeon's Car with X-Ray Plant Proposed for French Army and as Adjunct to City Hospitals

Also to Furnish Large Quantities of Sterilized Drinking Water for Troops in Camp

WHILE the automobile military ambulances which are intended for taking the wounded from the firing line to the rear for surgical aid and thence to the field hospitals are the subject of constant efforts for improvement, little has so far been done for giving those who have been so severely injured that they cannot be transported all the way to the field hospitals the benefit of an immediate and thoroughly aseptic operation, which is frequently absolutely necessary for their eventual recovery, especially if their injuries affect the bowels. In this respect the Boulant Surgeon's car which is being proposed as a regular equipment for the French army represents an important advancement in the humanitarian efforts for assuaging the horrors of grim war, and its value as an adjunct to emergency hospitals in large cities and industrial centers is also being considered.

According to the established routine in the medical field service, the wounded are first bandaged or tourniquetted where they lie in the field by the medical staff of the regiment, and are then carried on a stretcher to the first aid stations, which are barely beyond the danger zone. Here they receive further treatment and to each of them there is pinned a ticket of diagnosis, white if he cannot be moved to one of the field hospitals and red if he can. The Surgeon's Car is intended to get as close to these first aid stations as possible, to take care of the men with white tickets, but in most cases the service of the regimental ambulances will be required for covering the greater or lesser distance to a suitable place where such a car can be stationed in peace. A framework accommodating from three to eight stretchers has been devised by means of which automobiles of all descriptions may be transformed into ambulance wagons, and the motor trucks and delivery wagons which are subsidized by the French government are especially adaptable for this purpose. The ambulance shown in one of the accompanying illustrations is a transformed taxicab, however. While these ambulances are fairly well equipped to give medical service, experience has shown that their facilities cannot be relied upon where strictly aseptic operations are indispensable. And the field hospitals have no independent means of transportation.

Here is where the Surgeon's Car comes in. It is built on a truck chassis and is of the size of a large Paris omnibus. The body is divided into three parts. The wounded are entered at the rear in a vestibule compartment containing everything necessary to prepare for an operation; a tank with 200 liters of filtered water, a wash basin, drawers for clean blouses, aprons and other linen for the operator and other drawers for soiled articles. When the car has arrived at its halting place the tents which are folded up on its sides while it is in transit are raised, as shown in one of the illustrations, to afford shelter for the injured before and after the operation.

Two swinging doors lead from the vestibule compartment to the operating room which is in the middle of the vehicle and measures 3.20 meters in length with a width of 2.20 meters. It is lighted by skylights and electric lamps. The walls are of veneered and lacquered wood without joints and all the corners are rounded. The floor is a closely jointed mosaic of porphyry or similar stone which does not absorb moisture. Shelf-closets with glass doors contain a number of metallic boxes each holding all the tools required for one kind of operation; one for laparotomy (abdominal incisions), one for trephining, one for amputations, etc. When needed these boxes with all they contain are sterilized by heating in an autoclave, and this may be done while the car is moving. The special tools are actuated electrically by flexible cable. The operating table consists of a foldable metal framework adjustable to all necessary positions of the patient and a sectional top which is made of wood so that the X-rays may pierce it from below. A slide forming part of the frame permits a jointed support for a Roentgen apparatus to be adjusted in any desired position.

Hot and Cold Water Plentiful

All instruments serving for X-ray examinations, including diffusion plate, dynamo, induction coil, bulbs and the fluorescent plate with black cowl for examining by daylight, are grouped in a glass cabinet in the operating room. By means of two wires which hang from the ceiling and may be connected with the poles of the induction coil at any moment a considerable volume of ozone can be produced to sterilize the air in the compartment. A wash basin which is reserved for the operator is piped to receive either water which has been sterilized by the ultra-violet rays or hot or cold water from the autoclave. In a corner of the room the electric motor is placed which actuates the saws and cutting instruments and this can be switched to work a pump that draws the water for the needs of the vehicle. A long flexible hose connects the pump with stream, pond or well even at some distance, and the pumped water passes through a filter into a sterilizing apparatus operating with ultra-violet

French Club Will Run 1913 Grand Prix

Contest Will Be on a Fuel Consumption Basis and Will Be Decided in a Single Day

Course Must Not Be More Than 120 Miles From Paris, and Will Be Shorter Than This Year's

PARIS, July 16—Satisfied with the result of the Grand Prix run at Dieppe, the Automobile Club of France has already decided to hold another big race next year. As in the case of the 1907 Grand Prix at Dieppe, it will be run under a fuel consumption basis, the allowance being 20 liters per 100 kilometers, being at the rate of 14.1 miles to the gallon. A minimum weight of 1,763 pounds is imposed and a maximum of 2,204 pounds with tanks empty and no spares on board. The distance of the race will be about 560 miles to be covered in one day. There will be no limit to the number of cars that may be entered by any one firm, while the fee for each will be $800. If a minimum of 40 cars is not received by November 1 the race will not be held. With a view to making the race more spectacular than usual, the racing board has decided to run on a course of 28 to 38 miles round, compared with a course of practically 48 miles at Dieppe. Offers of a racing circuit have been asked for, it being stipulated that the center of the course must not be more than 120 miles from Paris.

The decision to limit the size of motors by restricting the fuel supply meets with a certain amount of criticism in technical quarters. The main advantage is that it will cause very close attention to be paid to carbureters and fuel economy and with the ever-increasing cost of gasoline this is a valuable feature. Against this must be set the additional complication in the holding of the race and the element of chance which is admitted by reason of a slight miscalculation in the gasoline consumption of the motors. The experience of 1907 was conclusive on these two points. Measuring the gasoline of a uniform specific gravity to all the racing cars was a delicate operation, and in the race itself it was found that there were cars with a consumption rate rather too high, and others with a consumption rate rather too low. The French, indeed, are convinced that they lost this race to Italy by a fluke in the weather conditions for which their best cars were not prepared. In all probability the cars taking part in the 1913 French Grand Prix will be only slightly inferior in cylinder area to the Peugeot which won this year. They will, however, be smaller than the racers of 1907, for on that occasion the fuel allowance was 30 liters of gasoline per 100 kilometers.

Careful Drivers Have Preference

Truck drivers should realize the great waste of money which they cause their employers by their reckless indifference to the laws of good and careful driving. They will find that their tire troubles decrease in a remarkable degree as soon as they begin to take pride in being considered careful, reliable drivers rather than would-be speed-kings at 17 miles an hour. Too many of them base their feeling of pride on their dexterity in operation of the machine, forgetting that their value to their employers lies, not in their ability to start the truck on high gear without quite tearing out the transmission, but in their applying themselves to their work with the idea of getting the best possible results in the least time and at the least expense, with some consideration for the more or less delicate and costly piece of mechanism placed in their charge. Too many drivers suffer under the delusion that, because a truck is built for rough service, it is capable of enduring all sorts of negligence and abuse, whereas it requires practically the same care as a pleasure car.

It is the careful truck driver who is getting the best position these days, because the truck owners have awakened to the fact that it is the driver, more often than the truck or the tires, who makes the use of a commercial vehicle expensive to maintain. Those that have retained their first drivers have generally done so because they found that they were reliable and efficient as regards driving, and, by no means to be forgotten, that they knew something about the science of loading, just how much weight to put on each wheel to get the best results with the least wear and tear on the tires, or evidenced some intelligence in this respect.

rays. The capacity of this installation reaches 600 liters of water per hour, so that a vehicle of this kind can supply a considerable quantity of water for neighboring troops, when this is desirable—this water being drinkable no matter how polluted its source.

A doorway leads from the operating room to the front compartment. Here the autoclave is located which is heated by alcohol to 130 degrees C. and also a water tank which can be heated if necessary with an alcohol burner. In the same compartment there is found the main dynamo which is driven from the 40-horsepower vehicle motor and supplies current for the electric motor and an auxiliary storage battery. A special small dynamo takes care of the lighting circuit. The driver's seat is entirely separated from the interior of the vehicle as in the case of an ordinary omnibus.—From *Omnia*, July 6.

General Construction Features of German Gasoline Motor Fire Engines with Centrifugal Ejector Pumps—Eventual Development of the Combustion Motor for Automobiles Presaged in the Activities of the World's Navies

GERMAN Fire Engines—Among the fire engines operating solely with gasoline motor power the type built by the Adler automobile works is notable, partly because it has seen much active service in the city of Frankfurt-am-Main and partly because its construction differs at important points from the other pure gasoline-motor engines. In all of these it is kept strictly in view by the manufacturers that a chassis closely resembling the chassis for an ordinary motor truck is one of the first requirements, if it shall be possible to furnish these modern fire engines at such low prices as will make them generally acceptable to small municipalities, without the patronage of which no economical mass production could be contemplated. To reconcile with this consideration perfect suitability for the fire-fighting service has constituted a problem leading to somewhat different solutions. In the N. A. G. and the Daimler-Marienfelde gasoline motor fire engines, which were partially described in THE AUTOMOBILE of July 11 and 25, the pump, which is a positive rotary-piston pump of special construction, is located and operated at the extreme rear of the vehicle. In the Adler engine, on the other hand, the pump used is a high-pressure centrifugal pump and the hose connections are made at the side of the vehicle—either side—at a point in line with the driver's seat. From front to rear the main parts follow in this order: Motor and clutch, then the pump through which passes the transmission shaft, then the change-gear and the cardan shaft to the rear axle. And the transmission shaft can be clutched either to the change-gear or to the pump, the pump shaft being hollow and surrounding the transmission shaft and the special clutch connecting the motor shaft either with the transmission shaft or with the pump shaft. Special gearing for driving the pump is thus avoided. The rear axle in the Adler engine is developed in the latest type, though not in the engine illustrated herewith, on the principle of parallel axles of which one supports the load and the jolts and the other transmits the driving effort to a spurwheel reduction gear on each of the rear wheels. The motor is governed down to a maximum of 900 revolutions per minute for traveling purposes but can be operated at 1,600 revolutions when driving the pump, and in that case a portion of the water flowing through the pump may be bypassed through a special tank where it comes in contact with the cooling-water pipes from the motor, thereafter returning to the pump system.

WHY CENTRIFUGAL PUMPS ARE USED

The advantages of the centrifugal pump, as compared with the reciprocating piston pumps used with steam fire engines, lie partly in their simplicity, their low cost of production and in the fact that they function best at high speed and may be connected with a gasoline motor shaft without the use of cumbersome reduction gearing. They are also much less subject to wear—as from the effect of sand in the water supply—as the rotating vanes do not rub against the walls of the casing, and they greatly reduce the wear of hose, as the uniform pressure at which they may be operated obviates the to-and-fro motion of the hose on the ground which always accompanies the use of the reciprocating piston pumps of steam fire engines. The great danger to the firemen on ladders which arises when the hose in their hands suddenly stretches itself out rigidly because some of the outlets for water have been stopped and the pressure thereby has been suddenly increased, is also avoided with the centrifugal pump which under all circumstances produces a pressure determined by its construction, its size, its speed and the pressure previously existing in the water supply, but can neither burst the hose by accumulated pressure nor stop the motor by abnormal resistance to its work. If the water outlets are all stopped the centrifugal pump continues to operate and, according to the data presented in the German trials, consumes under these conditions about 45 per cent. of the power required for the maximum throw of water. The same data indicate that a throw of 50 meters high and 75 meters distance is attained and that the evacuation pump admits of drawing water to the pump from a depth of up to 9 meters where no hydrant pressure is available.

THE COMPOUNDING OF PUMP PRESSURE

The centrifugal pump used is a multiple pump, see Fig. 3: a number of centrifugating disks are mounted contiguously upon the pump shaft, the water from the supply pipe arrives at the central admission port of the first disk, is thrown out against the wall of the enveloping casing and forward against a baffle disk with an increase in its pressure of say 3 atmospheres. With this increase it enters the central port of the next disk and is again thrown out with a new increase of pressure also amounting to 3 atmospheres. The third disk similarly raises the total pressure, so that, if only three disks are used, the total working pressure at the nozzle amounts to the initial hydrant pressure plus 9 atmospheres minus the friction loss in the mechanism and the hose. To obtain the best results there must of course be certain suitable relations between the speed and power of the motor, the volume capacity of the pump and the number and sizes of the hoses and their nozzles, and in these respects the system offers a large field for technical development. In the Adler fire engine pump made at the Sulzer-Ludwigshafen works, 5 centrifugating disks are arranged in parallel, as referred to, in one housing. A manometer on the pump outlet indicates the pressure at disposal.

The objection to the exclusive use of a centrifugal pump lies in its inability to draw water from a lower level when it is first brought to the fire until a continuous column of water has been established between the pump and the water supply, either by exhausting the air in the suction hose or by carrying a small water supply on the engine by means of which the continuous connection can be effected. It seems that the Adler engines for use in Frankfurt-am-Main can depend on hydrant pressure for this purpose anywhere within its sphere of action, as no special means for starting the pump are mentioned. In other similar constructions, however, either a tank holding 300 to 500 liters is carried and provisions are made for connecting this supply with the centrifugal pump and at the same time with the local water supply without interrupting the pump's work, or the centrifugal pump is supplemented by a positive air-evacuation pump. The Mannesmann-Mulag company at Aachen uses the tank system in the engine of its manufacture; the Sulzer concern makes a pump with an auxiliary evacuation pump as well as the type used by the Adler company, and the Ehrhardt & Sehmer company of Saarbrücken is mentioned as the producer of a centrifugal pump built in one with a positive rotary-gear evacuation pump in such manner that the latter can be thrown into or out of action by a spurwheel change-gear. The two pumps, the centrifugal water pump and the air pump, can thus be operated concurrently, which is of special advantage in cases where the water contains many air bubbles, as under these circumstances the water column in the suction hose is liable to be broken. The same firm has developed a six-way valve or faucet, with the effects of each position of the cock plainly indicated in words inscribed on the adjacent machine parts, by the use of which the correct handling of the engine by the crew has been much simplified.

With reference to the use of centrifugal pumps in the future it was stated by Fire Commissioner Schänker of Frankfurt at a public discussion of the merits of the various pump systems, that recent trials had led to a new construction which makes it possible to start pumps of this type working from a low-level water supply without first filling the suction hose or using an evacuation pump and also without carrying a tank with an initial water supply.—From *Der Motorwagen*, June 10.

Motor Warships Now Afloat—That the automobile motor is a type of combustion motor in which a great sacrifice of economy has been made to the need for small size and small weight is demonstrated by nothing else so plainly as by the enormous development which has taken place in the past few years in combustion motors of great power operating with cheap heavy oil as fuel—or with tar oil, vegetable or animal oil or almost any other liquid or liquifiable hydrocarbon—and using much less of these substances per horsepower-hour than the automobile motor uses of gasoline. With the price of gasoline steadily rising and no certainty that the supply will be sufficient ten years hence for the number of automobile and kindred motors which, according to the present rate of increase, will then be in operation, all developments of combustion motors which promise relief from the fuel problem step into the sphere of direct economical interest for users and makers of automobiles, and hereto comes the practical evidence which such developments afford of the perfectibility of the combustion motor in the matter of design. It had scarcely been foreseen, for example, that it would be possible to operate heavy oil motors on the two-cycle principle, and reversible at that, with practically the same reliability and fuel economy as had been demonstrated in favor of the four-cycle and irreversible type. Yet no sooner had the time come when the impending expiration of the first Diesel patents opened the domain of experiment and manufacture to the industrial world at large, before these discoveries were made which at once placed the combustion motor in the front rank as a power producer for ships of all sizes and reduced it to a question of time only when it would take the place of steam also for such stationary purposes as the driving of the rollers in steel mills, where reversibility is an important

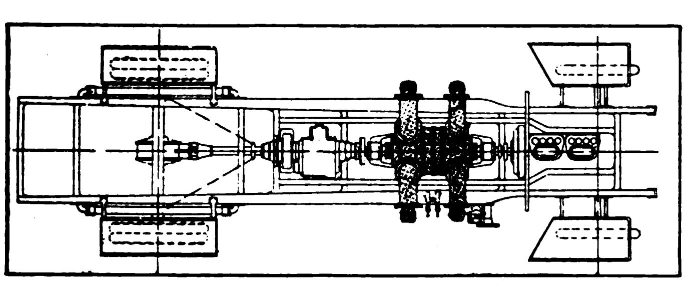

Fig. 1—Plan view of Adler fire engine chassis

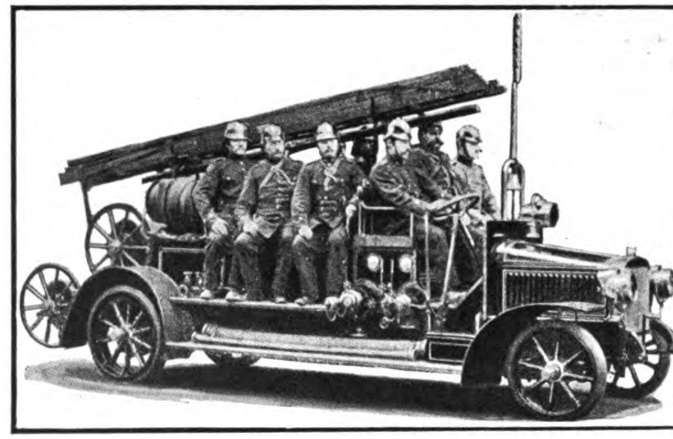

Fig. 2—Gasoline motor fire engine on a run

factor heretofore regarded as one of the indispensable advantages of the steam engine. In comparison, it was a small matter that it was also found practicable to use the combustion motor in its horizontal type as well as in its vertical type for ships, yet this fact, too, contributes to convincing the automobile maker that the type of motor to which he has pinned his faith is perfectible in unexpected directions and that things of direct interest to him are likely to come up in those branches of combustion motor manufacture with which at present he has little to do. The one feature in the heavy oil motor upon which more than upon any other, its success and adaptability seem to depend is the use of nothing but pure air for the piston to act upon during the compression stroke, as herein lies the avoidance of premature ignition and the availability of any liquid fuel which contains the required number of heat units. To the introduction of this feature in automobile motors, but without the great weight of motor parts and the use of auxiliary devices for fuel injection which the automatic ignition system of the heavy oil motors at present render necessary, the automobile industry is looking forward as the nearest possibility in sight and in this respect a close watch upon the efforts which are now put forth all over the industrial world for lightening the heavy oil motor may be said to be on the order of the day, with a better chance perhaps for direct benefits than may be derived from observing the labors of aeroplane motor builders, whose designs tend toward the turbine with sacrifice of fuel and economy considerations.

WHAT THE NAVY DEPARTMENTS ARE DOING

Just how far the practical development of large two-cycle combustion motors has already advanced is best shown by the data at hand with regard to their adoption in the navies of different nations, where progressiveness and technical insight are probably combined in as full measure as anywhere. Some information on this subject has been compiled by Ernest Trebesius, engineer, for *Der Praktische Maschinen-Konstrukteur*.

Several years ago the Russian government made the beginning by equipping the two gunboats *Kars* and *Adagan*, which are both of 630 tons displacement and 61 meters long by 9 meters broad, with 1,000-horsepower oil motors. The speed obtained was 14 knots, and as both boats were in the Black Sea service, where the supply of raw oil from the many wells in the adjacent country offered no difficulties, the conditions were economically as favorable as possible. [Dr. Diesel on his recent visit to America reported a number of other and later installations of oil motors in Russian warships.—Ed.] Italy started with motors of relatively small size installed in small torpedo boats and, encouraged by the results, is now placing Fiat heavy oil motors of 12,000 to 14,000 horsepower in a 650-ton torpedo-boat destroyer, which probably has been launched by this time, and for which a speed of 30 knots has been guaranteed. Twenty small Italian torpedo boats of 120 tons are at the same time being equipped with oil motors of 3,000 horsepower each, which will give a speed of 27 to 29 knots. The absence of smoke and smokestacks which betray the steam-powered warship at a considerable distance has been one of the first considerations favoring the adoption of the oil motor for torpedo boats and destroyers.

The French navy is experimenting with a 1,200-horsepower oil motor operated with tar oil—so that the fuel may be one under national control—and contemplates now to take the next step by placing a motor plant developing 30,000 horsepower from three oil motor units of 10,000 horsepower each in a man-of-war of the super-dreadnought type. So far as England is concerned, where naval development is kept well under cover, it is yet known that at one navy yard forty oil motors of about 500 horsepower each and arranged in groups of ten await installation in an old cruiser for trial purposes, it being apparently the intention to have each group drive one of four propeller shafts and to have in all 20,000 horsepower available in the boat.

Austria has built at the Danubius wharves at Fiume a 950-ton convoy for submarine boats with 2,000-horsepower oil motors giving a speed of 15 knots. The Turks had ordered several oil motor boats for coast defense in England, but when they were to have been delivered some of them fell into the hands of the Italians and the rest returned to England. Holland is placing 1,500-horsepower oil motors in three gunboats of 530-tons displacement.

In the commercial marine the most decisive step is to the credit of the East-Asiatic Trading Company of Denmark, which has already placed three oil motor ships of 7,000 tons each in active commission in the goods-carrying trade with Siam and China, and has five more similar ships under construction at English and Danish wharves. The three boats now running are the *Selandia*, the *Fionia* and the *Jutlandia* (Latin adaptations from the names of certain portions of Denmark), which are equipped with two groups of 1,200-horsepower oil motors each. For their very long trips to India they carry only 900 tons of oil, while with steam power they would have to carry 5,000 tons of coal. A very considerable gain in pay-tonnage is, of course, the result.

According to Lloyds Register twelve oil motor boats ranging from 4,500 to 8,000 tons and intended for trade purposes are at present on the keel at English and Scotch shipyards.—From *Der Praktische Maschinen-Konstrukteur*, July 4.

Properties of Nickelplating—Exhaustive experiments at Dresden have confirmed the best practice in the nickelplating trade. Iron in the anodes or the electrolyte is precipitated with the nickel, making it brittle and scaly. The current therefore gradually cleans such a bath of the harmful admixture. Salts of magnesium in the bath make the nickel coating smooth and silvery in color. High acidity makes a hard and brilliant but not a uniform, flexible or adherent coating. The addition of ammonium salts improves the uniformity while maintaining the brilliancy, but causes a powdery bloom if a strong current is used. A flexible and adherent coating is more readily obtained from a sulfate than from a chloride of nickel. An addition of sodium salt further improves a sulfate bath. The experiments go into all details.—From *Metall-Technik*, July 6.

Harking Back a Decade

What the Motoring Publications of 10 Years Ago Had to Say on Live Matters of the Day

Cars So Scarce That Premiums Are Offered for Second-Hand Machines in Good Condition

FROM *The Automobile and Motor Review,* August 2, 1902: The winning of the Gordon Bennett cup by England has placed a new face on the question of road racing and opens up a long vista of promising possibilities, both of international sport and material benefit to the motor car industry. We believe that an immediate announcement of the Gordon Bennett cup race over English roads next summer, if such were possible, would be hailed with delight by American, English and French builders alike, as well as individual motorists of the three nations.—*Editorial.*

The question of automobile insurance against fire is again being agitated. A new policy, originating in Connecticut, has been framed to meet modern conditions of automobile use. The policy covers automobiles while within buildings, on board railroad cars or ships. The rate is 3 per cent. The old form of policy under which the insurance on the building itself was voided by the entrance of the automobile, was 2 1-2 per cent.

Banker Brothers in Pittsburgh, one of the half-dozen big firms of dealers in that city, reports selling thirty-five Peerless cars, twenty-three Pierce automobiles and almost 100 smaller machines so far this season.

Premiums Offered for Used Cars

Stories of premiums for second-hand cars are common. G. W. Hayden, of Chicago, tells the latest. He was offered $2,500 for his Winton, which had been driven 2,000 miles. The car cost him $2,000 and he took the $500 profit.

A suggestion is being considered in legislative circles to pass a law requiring owners of automobiles to register them, pay a license fee and exhibit a number plate to identify the car. While the motorists have entered a protest against such a law, it is thought the chances of enactment are good.

A gasoline shortage has made itself felt in Eastern Connecticut. Not a gallon of 74 test fuel is available at New London. In other places where there is still a small supply the price has bulged up from 10 cents to 30 cents a gallon.

Ernest Cuenod, vice-president of the Swiss Automobile Club, has filed a belated protest against awarding the middle-weight gasoline car prize to Percy Owen as a result of the outcome of the speed trials on Staten Island in May. Cuenod claims that his understanding of the rules was that the prize should go to the driver who made the best time in the first heat and that the subsequent heats were to be mere exhibitions. He beat Owen in the first heat, but in the second Owen's time was over 5 seconds faster than that of his rival in the first heat.

L. A. Weston & Company announce a new artillery wheel to interchange with the wire wheels now being produced by that company.

The Oldsmobile Company, of Cleveland, continues to place cars at the rate of one a day. The company is several weeks behind in its deliveries.

The assets of the Milwaukee Automobile Company which were appraised at $8,700 have been sold to Herman Falk, one of the stockholders in the defunct corporation for $925.

Steam tonneaus designed by W. M. Gage, of Saratoga, N. Y., are to be manufactured in that city. Mr. Gage states that the location of the boiler under the hood renders the occupants of the car safer than they would be otherwise.

Tire Repairs on the Road

Improper Inflation the Cause of Much Tire Trouble—Proper Methods of Inserting Inner Tubes

Pressure Will Sometimes Decrease in New Tires Owing to Expansion of Latter

IN these days of the perfected automobile, 90 per cent. of the annoying delays on the road are due to tire troubles. No car is immune from them. The expensive, high-powered and elaborate machine is just as liable to be seen drawn up at the side of the road undergoing tire change or repair as is the low-priced, diminutive runabout.

This condition of affairs, although lamentable, must obtain until such time as a satisfactory substitute is found for the present pneumatic which is well nigh as perfect as the tire maker can make it. No one will deny that the present automobile tire is more or less of a nuisance, but as yet no one has come forward with something equally as good and as practical to take its place. And until that time, we should make the best possible use of what we have with us.

The tire is subject to a number of maladies which are not so much characteristic faults as they are those of the careless driver. The automobilist who drives with utter disregard for his tires, and only remembers that they are part of the car's equipment when puncture or blow-out occurs, is the first to denounce pneumatic equipment in general and the make he is using in particular. And so it goes. Many tire troubles which are really due to negligence or carelessness on the part of the automobilist are unjustly charged to faulty materials and workmanship.

Reputably made automobile tires of today are good for at least 6,000 miles if ordinary care is taken to get the most out of them. Cases are on record where they have run from 8,000 to 17,000 miles in ordinary service, however. These are not exceptional mileages by any means, one manufacturer citing an instance where a tire gave 40,000 miles of service. This latter figure must be considered exceptional, however. On the other hand, many automobilists do not get over 3,000 to 4,000 miles out of the best tire made, if there is any such doubtful distinction between the well-known makes. Such low figures can only be the result of careless driving.

Uniform Tire Inflation Requisite

Improper inflation is responsible for more tire trouble than anything else. Many automobilists do not realize this. They fill their tires perhaps to the proper pressure and pay no more attention to them until they are quite noticeably deflated, when they are again treated to a supply of air. Such a procedure means that the tires are running under-inflated half of the time, because even when there is no noticeable leak, there are a number of ways in which the air pressure may be reduced. It is, therefore, a bad policy to simply inflate the tires and then forget all about them until they are quite apparently below pressure. Test this pressure from time to time to make sure that there has been no reduction. For this purpose an accurate pressure register is almost indispensable.

Most automobilists do not realize that the valve is quite apt to leak slightly unless it seats with extreme accuracy. If there is any dirt on the seat it is doubtful if the rubber washer can hold tightly enough to resist the air pressure. If this washer is worn or out of shape, then there will most surely be a slight escape of air, while, if the threads of the valve stem have been damaged, there is further possibility of loss of pressure.

New tires usually expand slightly after being in use for some time, so that their pressure will decrease somewhat, even if there is no leakage from any source whatever. This is a fact which the average driver does not know, but one which the Michelin company asserts is quite common. It is also commonly accepted that the outside temperature has a great deal to do with the pressure in the tire, and that when driving over hot pavements and country roads, the heat expands the contained air dangerously. This consideration often prompts the would-be careful driver to let some of the air out of his tires when driving under such conditions. As a matter of fact, the increase in the air pressure due to this slight expansion is so small as to be almost inappreciable on the tire gauge. Such a small increase may be disregarded, while the detrimental effect of running with the tires under-inflated is much more to be guarded against. It is far better to leave the pressure as it was.

Over-inflation is not to be recommended either, for, aside from the fact that resiliency and flexibility are sacrificed by inflating above prescribed pressures, the fabric and the rubber are strained and stretched harmfully. Pneumatic tires are intended to partially absorb road jars and rough spots, but when abnormally inflated they become but little superior to solids in this respect. In short, their purpose is defeated. Further, highly inflated tires, through the extra vibration to which they subject the entire mechanism of engine and chassis, tend to increase the car's rate of depreciation to a marked degree.

Inserting Inner Tubes in Shoes

In the fitting of inner tubes in the shoes or envelopes, a number of things must be remembered, for on this operation largely depends the possibility of blow-outs. Cracks, creases, pinched places, wrinkles, bunches, twists—all are enemies of the tube and must be rigidly guarded against. The driver may reason that, since he is in a great hurry, he cannot afford to spend much time in getting the tire together. Painstaking fitting of the tube may take longer at the start, but it will save time and trouble in the long run.

Before attempting to fit the tube within the envelope, the air should be completely removed from the former. First remove the valve cap, then the entire valve and spring. Start at the point of the tube opposite to the valve-stem and roll up the tube toward the stem, forcing the air from the farthest part of the tube toward the opening. After the tube has been rolled up tightly and all the air expelled, replace the valve parts so that no more air can enter.

Having made sure that there is no dirt or other foreign matter on the inner surface of the envelope and that it is free from cuts, the next thing to do is to sprinkle powdered talc or soapstone around this inner surface. This should be done carefully, just enough being used to make a smooth backing for the tube. Too much powder is apt to form into hard lumps which chafe the tube in time in just the same way as dirt or pebbles would. On long runs the slight rubbing of the tube and envelope surfaces on one another heats them somewhat, and the right amount of this powdered material acts as a lubricant to reduce this frictional heat.

Having carefully prepared the envelope, take hold of one side of it firmly about a foot from the hole for the valve-stem, pulling it open so that the tube may be inserted well into it with the other hand. Place the stem in position first, then proceed to insert the tube in sections of about a foot at a time, being careful not to twist or stretch it. When the last section is to be inserted, if the tube has been properly handled, there should be no apparent extra length. Now partially inflate the tube just enough to remove all the wrinkles. Then run the hand around inside the envelope between it and the shoe to smooth out any slight bunches and to equalize the tension all around. If all wrinkles, bunches and the like have been completely removed, the shoe is ready to be placed upon the rim, but not before. It is a mistake to place an envelope in position when creases or wrinkles are still to be seen, for when the normal pressure is added they will simply deepen and eventually crack. A blow-out will be the ultimate result.

Making Limousine Bodies Water-Tight

How to Provide Against Leakage of Rain Around Bottoms of Frameless Glass Windows and Doors

How the Work Is Done Is Shown in a Series of Detail Side and Sectional Drawings

Fig. 1—Section of limousine door

FRAMELESS glass for windows on closed bodies has become so generally used, that progressive bodybuilders have already set about trying out different methods to overcome the one objectionable feature that this style of window has, *i.e.*, the entrance of water around the bottom of the glass when it rains. The amount of rain that sifts in at the bottom of the glass is not so much as would be supposed, and where the body is of all-metal construction and proper provision has been made to take care of the leakage, it is not really a serious matter.

Fig. 1 is a section cut lengthwise through the door of a limousine and illustrates the difficulty mentioned. It will be noticed that the glass is longer than the opening in the door and that the bottom of the glass is below the top of the bar, on which ordinarily the glass frame is made to rest for the purpose of forming a watershed. In this illustration, the glass is always supported by the lift strap and the rain leaks in at the opening indicated by the arrow; the majority of bodies in which the frameless glass is used are constructed in this manner.

Fig. 2 is a section of the side elevation of a limousine body, showing the door and part of the rear side window. This is the first of the illustrations showing a different method of assembling the frameless glass in the body to overcome the difficulty shown in Fig. 1. This illustration, Fig 2, and the succeeding one, which is a section through line W-X, and marked Fig. 3, shows the side and end views of the glass in the raised position, and the metal channel hooks that support the glass and make a water-tight connection between the glass and the door bar are indicated by the letter A on Fig. 2 and A2 on Fig. 3.

Fig. 4 is an enlarged illustration of the preceding one, Fig. 3, and the channel book A2 is more clearly shown. The glass rests in this channel without any fastening other than the pressure of the channel members against the glass, and there is also a thin rubber channel between the glass and this outer metal channel.

Some Details of Construction

Fig. 5 is the channel in which the glass slides up and down. Near the top of this figure a piece is broken out and a cross section is shown to illustrate the end view. This channel can be either of wood or metal; in this case wood is used, and Fig. 8 is a duplicate illustration made larger and dimensioned. The wood channel is entirely covered with broadcloth, which is cemented to the channel, the edges meeting at the back.

Fig. 9, which is directly above, is a cross-section through line U-V, Fig. 4, and shows the assembled glass and channel in the pillar. It will be noted that the groove in the pillar is wider than the channel, and looking at Figs. 3, 4 and 6 the reason for this is shown. In Fig. 4 the glass is supported by the hook A2 engaging over the iron fence of the door bar. This is accomplished by forcing the glass outward and bending the channel, the spring B assisting to hold it in position. When the glass is to be lowered, as shown on Fig. 6, it is raised by the lift strap till the hook is clear of the iron fence, when the channel will assume a straight position and the glass can be lowered.

Fig. 7 shows the pillar without the channel in position, and R is the groove to receive same. When assembling this channel in the pillar, it is only fastened by one wood screw at the top; the groove R is smaller at the bottom to prevent the channel from rattling, but it does not prevent it working to assume the position required on Fig. 4.

In the case of the door, the glass is put into the groove through the opening at the top, whereas the other glasses must be put in from the inside, and as the channel must be put in place at the same time as the glass, it can readily be seen that a channel the full length of the pillar run cannot be assembled in place after the job has been trimmed; therefore these side channels cannot be much longer than the glass. Below this, to the bottom, the runway is formed by a groove in the pillar, this groove being lined with cloth the same as the channel. The channel is fastened at the top with a screw in the same manner as that of the door, the lower end having a spur on the back side that engages in a plate let into the pillar groove. The channel oscillates to perform the same function as illustrated in Figs. 4 and 6, and the spur working in an elongated slot in the plate controls the movement.

The method above described is a practical working plan and is in actual use; it is not expensive to put in and it insures the car owner against any possible damage that may be done by water leaking into the body through the bottoms of the windows.

THE consumption of cooling water is about the same for most of the small alcohol and benzine motors in the German market—namely, about a quart per horsepower hour. This consumption is about the same whether cooling is effected by evaporation or by water circulation, the former being the more simple.

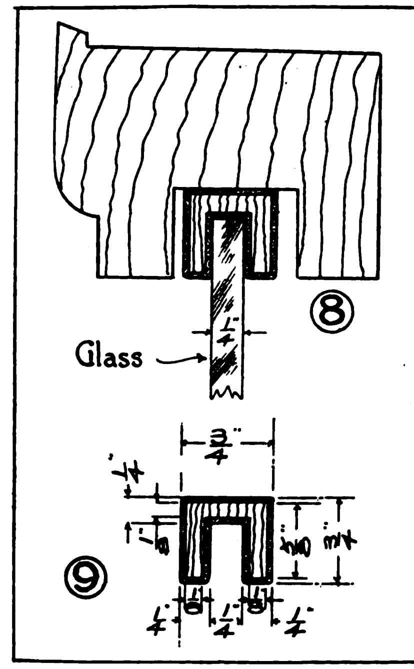
Mechanical Details of Grand Prix Winner

Arrangement of Valves Is One of the Distinctive Features of Motor-Intake and Exhaust Valve Camshaft

Used Shaft Drive, Although Previous Peugeot Racing Models Were Equipped with Chain Drive

PARIS, July 21—There are numerous distinctive features on the Peugeot car with which Boillot won the French Grand Prix. The racers were built to the design of M. Vaselot, chief engineer of the Peugeot company, and are lightweight machines with a very efficient motor. The four cylinders are a block casting of 100 to 200 millimeters bore and stroke, compared with 155 millimeters bore for the racing Fiats. The entire power plant—motor, clutch and gearbox—is carried on a single-piece channel section subframe having the form of an elongated U, the two extremities being carried on a cross member and the front end being attached at a single point to a very stout cross frame member beneath the radiator. This gives a three-point suspension. The lower portion of the crank chamber is bolted to the subframe along its entire length, and the upper portion bolted on this. The lower portion of the crankcase is deeply ribbed to assist in cooling the oil, and the forward portion forms a deep, almost circular oil well, also with radiating fins.

The most distinctive feature of the motor is the valve arrangement. There are sixteen valves inclined in the head at 45 degrees, thus giving a hemispherical form of combustion chamber. The same position is used on the Fiats, but the distinctiveness of the Peugeots lies in the use of two camshafts, one for the intake valves and the other for the exhausts. At the motor front is a vertical shaft, driven from the crankshaft by means of bevels. The two camshafts extend fore and aft, immediately above the line of valves, and each is contained within an aluminum housing, also carrying the tappets and return springs for the tappets. The camshaft housings are mounted some distance above the top of the cylinders, there being a gap between the tops of the cylinders and the bottom of the housing of between 3 and 4 inches, a series of stout steel bolts projecting from the cylinders serving to carry the housings. Obviously this arrangement has the advantage of removing the valve-operating mechanism entirely from the heat of the motor. At the forward end, and practically on a level with the top of the cylinders, is the timing gear housing, this housing receiving the vertical shaft and the forward ends of the camshafts. By the use of two camshafts the heads of the cylinders are left free for the spark-plugs, these being but one per cylinder. A cross-shaft drives magneto and water pump.



Figs. 8 and 9—Enlargement of Fig. 5, showing dimensions of slide channel and glass

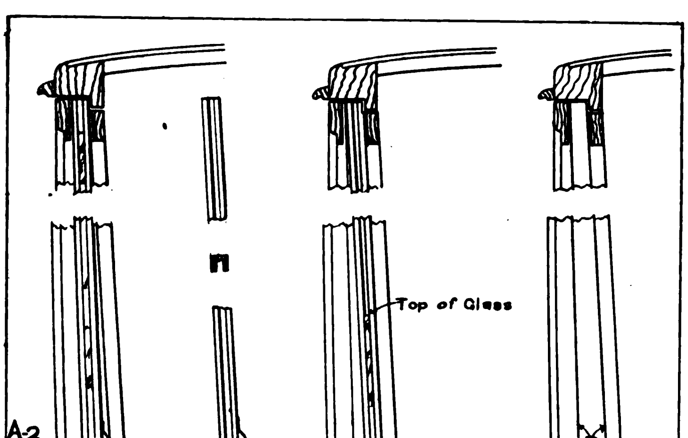


Fig. 4—Showing channel hook that supports glass. Fig. 5—Section of slide channel. Fig. 6—Illustrating operation of lowering glass. Fig. 7—Pillar without channel in position

The lower end of the downward extension of the vertical shaft drives the oil pump contained within the circular front portion of the base. The maximum oil pressure is 16 kilos to the square centimeter, compared with only 4 or 5 kilos on the most advanced types of touring or racing cars from other factories. In view of the high pressure special means had to be taken to prevent leakage. All the oilways are steel tubes welded in position. The oil is carried at this high pressure to the five plain bearings of the crankshaft, through the hollow crankshaft to the connecting-rod ends, and up the tubular connecting-rods to the wristpins. The camshafts being entirely independent oil is pumped by hand to the rear end of each shaft, an overflow being provided at the center of each housing to give a return to the base of the crankcase. A small pump on one of the camshafts keeps up pressure on the gasoline tank.

Abandoned Chain for Shaft Drive

Although Peugeot has always favored chain drive for racing cars, these models were built with a final drive by shaft and bevel gearing. With a correct distribution of the weight they held to the road perfectly, showing their superiority over the chain-driven Fiats at speeds of more than 10 miles an hour. The clutch is of the multiple-disk type running in oil. The gearbox provides four speeds with direct drive on fourth and the final drive is by propeller shaft to floating type of rear axle. The cars are not equipped with either distance or torsion rods, all the drive being taken through the broad semi-elliptic springs.

To eliminate, as far as possible, violent bouncing of the car at high speeds, very stout, broad leather bands form a bracelet around the rear axle and one of the rear frame members. No attempt is made on these cars to reduce head resistance by the use of stream-line bodies.

Defining Bore and Stroke; Best Valve Dimensions for Touring Car; Repair on Badly Worn Stearns Axle; Mysterious Blow-Outs; Criticises Test on Motor; Trouble Shifting Gears; Livery Maintenance Cost

Wants Several Terms Defined

EDITOR THE AUTOMOBILE:—1. What is the real meaning of bore and stroke, and why is the stroke longer than the bore?

2. What is the essential value in a four-speed car, and what advantage is claimed by the makers over the three?

3. Why do some cars have direct drive on third and some on fourth, and which uses the most gasoline?

4. What are semi-floating and floating axles?

Shreveport, La. X. Y. Z.

—(1) By bore is meant the diameter of the motor cylinder. Stroke refers to the diameter of the circle through which the crank swings. In order to expand the gas as much as possible the stroke is most often larger than the bore.

(2) You are referred to the July 18 issue of THE AUTOMOBILE on page 130 for a full discussion of this matter.

(3) The majority of cars in America having a four-speed gearbox have the direct drive on fourth, fully 75 per cent. having this arrangement. The advantages of this arrangement and the reasons are also discussed in the article referred to under question 2.

(4) In both the floating and semi-floating rear axles the weight of the car is all carried on the housing of the rear axle. In the floating type the axle can be withdrawn by simply removing the hub cap, while in the semi-floating axle the end is connected rigidly to the wheel.

Touring Car Valve Dimensions

Editor THE AUTOMOBILES—Will you kindly give me the best dimensions for overall diameter of valves with conical seats and lift of same for touring car of following specifications? Four-cylinder, L-head, block motor, 4 1-2-inch bore by 5 1-2-inch stroke. Direct drive ratio 3 to 1. Car weight complete, unloaded, 2,700 pounds. Also for same car equipped with four-cylinder, L-head, block motor with 4 1-2-inch stroke.

C. WILLIAMS.

Philadelphia.

—The valves for both motors should each have a diameter of 2 5-8 inches and a lift of 5-16 inches.

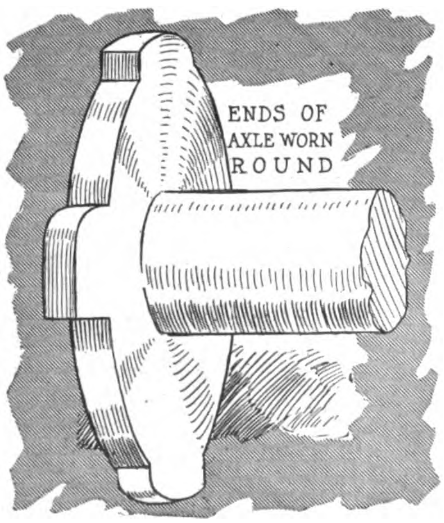

Fig. 1—Showing wear on axle end

Neat Repair on a Rear Axle

Editor THE AUTOMOBILE:—The following is a repair which I think would interest many of your readers as it is rather novel.

The driving axles on a Stearns 30-60 had been worn round at the wheel end, as shown in Fig. 1, and naturally occasioned a great amount of trouble. As I have a well-fitted shop, being equipped with good tools and a small lathe, I determined to make the repair myself. The first step was to saw off the rounded edge, as shown in Fig. 2. The sawing was continued to some depth, the object being to slot the metal, in order to take a small key of the shape shown in the same illustration. The edges of the slot were trued up with a fine file as the key is to fit very tightly into the slot. The keys should be a driving fit and can then be tapped in lightly with a hammer, as shown in Figs. 3 and 4. After they are driven in place, as indicated in the various illustrations showing the work on this job, it would be practical to drive the car and it would be reasonably safe. To hold the keys in place against side slip they are tapped out to take a machine screw, as in Fig. 5. After this is screwed in far enough to hold the key against slip it is sawed off flush with the surface of the key and filed smooth. This repair will wear indefinitely and will take up all the lost motion which would be

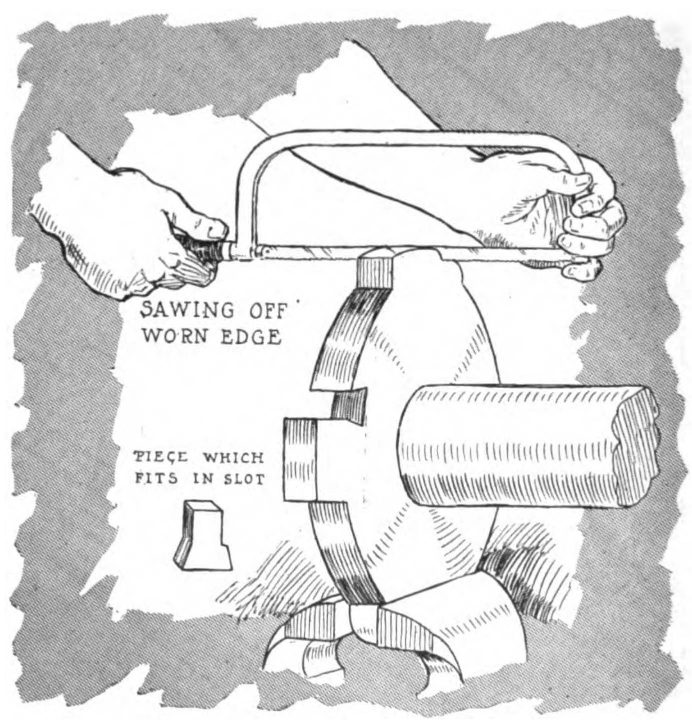

Fig. 2—First operation in making repair on Stearns axle and key-piece

found should the axle be left as it was in the first place. The most important thing to remember in connection with the work is that extreme accuracy must be used in the fitting or the repair will not last.

New York City. CHAUFFEUR.

Has Blow-Outs Frequently

Editor THE AUTOMOBILE:—In your issue of July 11, Mr. Sauermilch tells of his troubles with tubes often blowing out without cause and I wish to say that I have had the same trouble, but my casings are the straight-side style instead of the clincher. They also have a canvas flap covering the tube next to the rim which I think caused the trouble by getting a fold in it, no matter how careful I was in putting in the tube. As Mr. Sauermilch says, it nearly always happens while the car is standing idle, but I have had it happen two or three times on the road. I put in a new tube, thinking maybe it was the tube's fault, but it blew out before being run 25 miles and this time on the road. I then bought a new casing of a different

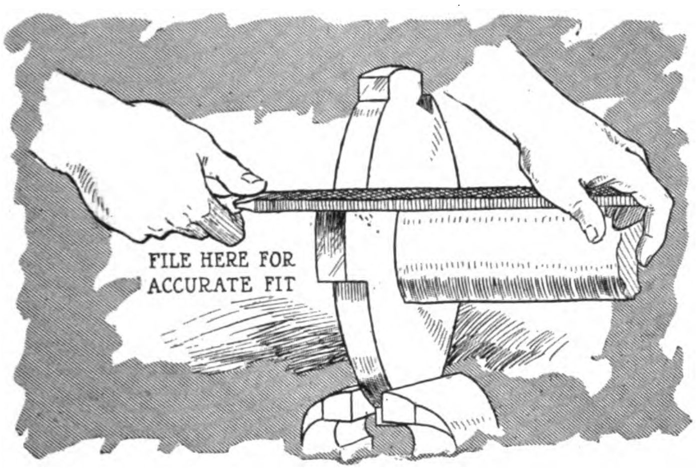

Fig. 3—Filing the groove in order to secure most accurate fit

make, straight-side also and without the canvas flap, and put it on the same wheel and had no more trouble from that wheel, but still have another one that gives trouble. Do you think it would do to take out the canvas? I have been afraid to do this as the beads on the casing are different than the new one. I have also thought of putting in a reliner, but don't know if it would help any. The trouble began after the car had run about 1,000 miles and the tires were new.

Orchard, Iowa. W. R. WORSELDINE.

—It should do no harm to take out the canvas flap, but it is doubtful if it is that which is giving the trouble, although it is a possibility. A reliner would harly prevent the trouble either, as it would make it even harder to get the tube properly into the casing. It is impossible to state the cause of these blow-outs without seeing the tire, but with a proper fit of the inner tube and proper pressure on the tire, these things should not occur. Perhaps the experiences of other motorists along similar lines could help you. THE AUTOMOBILE will gladly publish any suggestions regarding this case.

Disagrees with Test Results

Editor THE AUTOMOBILE:—Referring to the test made in the laboratory of the Automobile Club of America by H. Chase, on a 48-horsepower automobile engine, permit me to say:

Since the fan and the radiator designed for the engine are indespensable thereto, both should have been included in the test. The former takes power. How much? Its speed is correct only within very narrow limits. What are those limits? Instead of using an ideal cooling system, Mr. Chase should use a blower, imitating the wind met on the road, as the great variety of conditions there ought to be duplicated as far as pos-

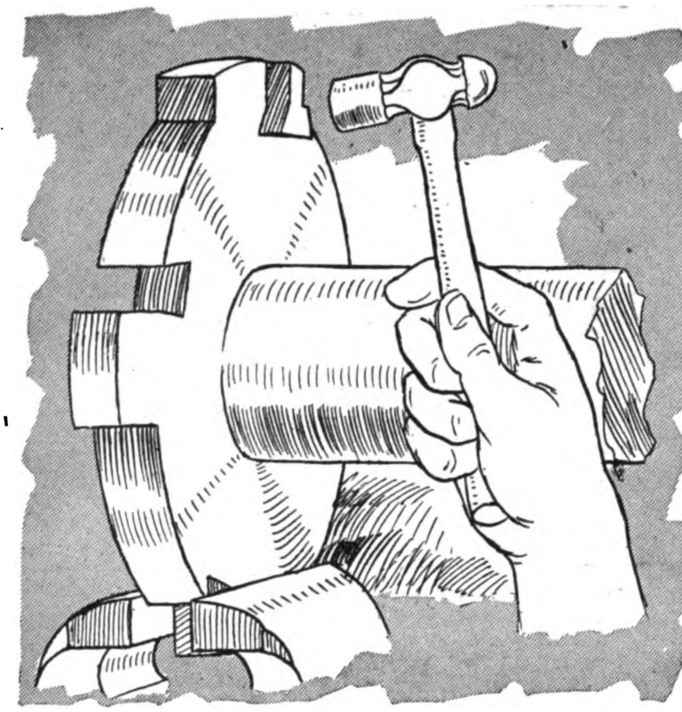

Fig. 4—Tap the piece carefully into place in slot until flush

sible. When Mr. Chase says that the engine, when driven by a motor (not under its own power), pumped less water than it did before, and when he then places the causes as probable I wish that he had gone a little further and ascertained just what the cause was. Since I believe, judging from my own investigations, that there are causes not yet discussed which are in part responsible for the noted difference, I suggest the following test: While the motor is firing regularly, stop the pump and note what syphon action takes place. Next, place the radiator in such a position that, theoretically, the syphon action ougt to be interrupted. Then place it so that it will be actually stopped. Unless I am wrong there will be a difference in theory and practice which must have causes other than those known.

I would like to see the indicator cards taken at the exhaust, since I am convinced that we have much to learn in that direction. Among other things it will be noticed that the exhaust gases do not leave the cylinder in a stream during the time the exhaust valve is open. When Mr. Chase says that he has found oxygen in his test tubes while examining the exhaust, I be-

Fig. 5—Final step in repair

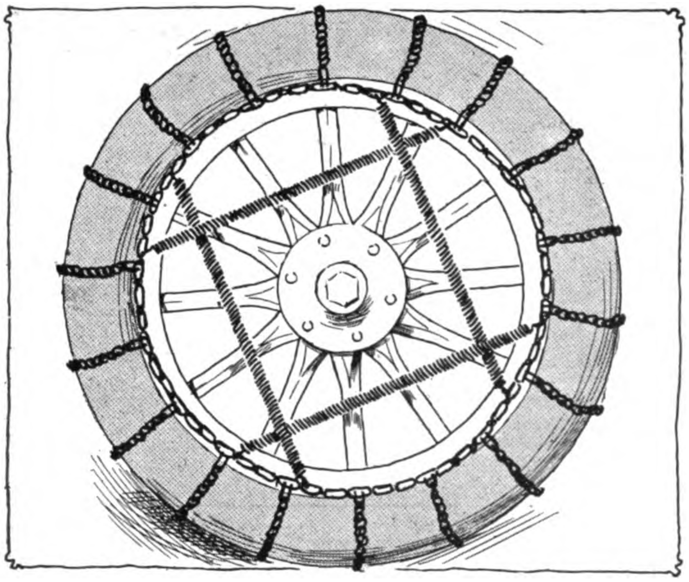

Fig. 6—Device used by reader to take up slack in non-skid chain and to prevent noise

lieve that he will not be able to duplicate for the following reasons:

I once attempted to preheat the manifold of an engine by tapping a 1-8-inch copper tube of a total length of about 2 feet onto the exhaust close to the exhaust port, and winding it in a coil around the intake pipe, with this result: only cold air and water would pass through. For Mr. Chase to point his test pipe in a direction to meet the outgoing gases was to take a step to no purpose. A jet action cannot be obtained on the exhaust side of an engine. At least, my attempts in that direction were failures. The Hornsby-Akroid people in England also failed in that, although an experimental engine was an apparent success. If Mr. Chase will increase the diameter of his tapoff considerably and take it for granted that gases leaving exhaust port expand in all directions at once, he will find no more oxygen. When the volumetric efficiency of a motor is mentioned I am interested in the temperature of the air after leaving the gasoline nozzle, at the valves, within the cylinder at the beginning and at the completion of suction stroke. Although a given volumetric efficiency may be recorded, the horsepower delivered will alter with the temperature of the air. Does the manifold, when forming a part of the engine casting, tend to unduly increase the temperature of the air and thereby the oxygen present? If so, would it be advisable to put a jacket on the manifold to keep the heat away from it? To what an extent do the hot cylinder walls repel the air by expanding it? I believe that all these questions need to be answered.

The definition of volumetric efficiency by Mr. Chase I do not think a happy one. One might think, in reading it, that it was possible that the incoming fluid might differ from the outgoing. The following definition I believe to be better: The volumetric efficiency of an engine is the difference between the actual inhaling per stroke per piston and its displacement.

In connection herewith I would like to see a comparison with an engine fully scavenging its cylinder, the Atkinson, for example, and a conventional engine. I believe that the increase in volumetric efficiency in the former is less than 5 per cent., and in thermal efficiency the increase is less than 2 per cent. Would Mr. Chase make a comparison?

If I were to sell a horse to a farmer, assuring him that it was suitable for plowing and then, although it did plow, it soon gave out, had I then sold the man what he wanted?

To put it in the shape of questions: How is an engine limited? Why is it limited? What limits it? Why, for example, is an automobile engine not suitable for a boat? To say that a boat is always going uphill is no answer, although I made it, not having a better reply. Why will an engine not deliver the same horsepower continually, say for a month? What prevents? We are displacing the horse, asserting that the motor does not tire, but this does not seem to be so. Why?

New York City. P. G. Tismer.

Two Useful Illustrated Tips

Editor The Automobile:—An ordinary claw hammer is a useful tool for opening hooks as shown in Fig. 7 or for removing broken cross-chains from tire chains. It is sometimes difficult to pry them open with a screwdriver.

Four springs for screen doors may be hooked across the tire chains, as shown in Fig. 6 and will take up the slack, thus diminishing the liability of the chains striking the mudguards.

Allegheny, Pa. Murray Fahnestock.

Cost of Livery Maintaining

Editor The Automobile:—Please give me the following information with the Case 40 as an example:

In using this car for livery service about what should the charge per mile be to cover all expenses and maintain the car up to the time when it would be so worn out that it would not pay to add more repairs on it to keep it in running condition? Above all this expense, how much would have to be added per mile cost so at the time the car was of no more use I would have enough money to purchase another car of the same cost as the original?

About how many miles should a car of this size and type run before it is worn out? Please give me this information itemized, *i. e.,* how much cost for gasoline, tire, lubricating oil and grease, insurance, maintenance for repairs, depreciation and driver. Car to be run over country roads.

Rupert, Idaho. F. A. Nelson.

—All these figures cannot be accurately determined by estimate. Some of them should be taken from an observation of the car itself working under the same circumstances as those you mention. This includes the cost of gasoline, oil, tires, etc. An estimate based on observing other cars would be as follows:

Gasoline, 2 cents per mile.

Oil and grease, 1-5 cents per mile.

Tires, 4 cents per mile.

Insurance, 1 cent per mile.

Maintenance would vary greatly; allow 2 cents per mile, which should include annual overhauling.

Driver, 10 cents per mile.

Depreciation sufficient to pay for new car after 150,000 miles, an arbitrary figure, 1 1-3 cents per mile.

Total: 20.5 cents per mile, without profit.

This is based on running the car about 10,000 miles per year, during which time the expenses would total up $2,050. If you charge 40 cents a mile the profits on one car should be $1,950 per year, provided that the car was only run 10,000 miles in the year. By keeping the car busier than this, the expense relative to the mileage would be reduced and the profits correspondingly increased.

Careful driving over rough roads will be a necessity to reach the figures given above.

Has Trouble in Shifting Gear

Editor The Automobile:—1. I have much trouble in sliding my gears into mesh and, after I get them in, I have just as much trouble in getting them out. Gears are of the sliding type with three speeds forward and one reverse.

2. After running on third speed a little while, the engine slows down and sometimes stops altogether. My machine is a four-cylinder, 40-horsepower Wood.

3. How far should I advance my spark and throttle levers while traveling on level road?

Plainfield, N. J. Reader.

—(1) The trouble is that you do not declutch far enough. This might be caused by the fact that you simply do not press far enough on the pedal or it might be that the pedal cannot go farther forward owing to faulty clutch adjustment or, as sometimes happens, the floorboards might not be slotted deep enough to allow the pedal to go down as far as it ought. The trouble is no doubt due to the continued engagement of the clutch to some extent while you are trying to shift gears.

(2) This looks like a matter of faulty fuel feed, but there is insufficient data in your question to answer fully. Weak batteries might cause the trouble if you do not use a magneto.

(3) After you have the motor started, turn the throttle lever on the steering wheel back as far as it will go and control the speed with your foot. The spark should always be advanced as far as possible without allowing a knock to develop in the motor.

How to Avoid Carbon Trouble

Editor THE AUTOMOBILE:—In removing carbon from the cylinders with kerosene, as suggested in THE AUTOMOBILE, how long should the kerosene be left in the cylinders before starting the motor?

Greenwich, Conn. CARBON.

—Leave the kerosene in the cylinder at least overnight and be sure to put it in while the motor is hot as the object is to dissolve the carbon with the vapor of the kerosene which will not be formed if the kerosene is placed in the motor after it has become cold. A tablespoonful put in each cylinder just after the car has stopped running every time you return home will keep your cylinders free of carbon. When starting the motor again open one pet-cock at a time for a few seconds to aid in blowing out any accumulated matter.

Tight Tappets Consume Power

Editor THE AUTOMOBILES—Will you kindly advise me as to the best adjustment of the valve tappets on my 1912 Cadillac? I have the tappets adjusted so that the motor runs very quietly. I have them tightly adjusted, thus eliminating any noise that would occur with loose tappets. Kindly advise me if this adjustment would cause a loss of power or heat the motor in any way. I wish to say that the motor does not skip at all with tappets drawn up snugly.

Lynn, Mass. SUBSCRIBER.

—The valve tappets must have clearance when the motor is cool or else you will lose power. When the motor becomes warm the valve stems expand and hold the valves from their seats. The proper clearance between the bottom of the valve stem and the top of the push rod when the motor is cold should be such that a visiting card can be slipped between them and just fit. Even when warm there will be a very slight margin of clearance. In this case, however, this should be no more than the thickness of an ordinary sheet of paper.

Another View of Starter Problem

Editor THE AUTOMOBILE:—The vigor in which the Editor of THE AUTOMOBILE expressed his thoughts on the starter problem, page 146, July 18, is worthy of a better cause. Engineering problems are not solved in a day or a year. They are like other problems, the pressure to shape comes from many sources. The engineer would change his engine to match the newcomer (the starter), but the prudence of the manager forbids. Salesmen hand in contradictory reports, one territory complaining that several sales are lost because the starter was not electric, another territory calling for a priming device. But lay the considerations aside for the moment. Forces at work today differ but little from those of yesteryear. When the first railroad coaches were built, the stage-coach was placed on rails. Who pretends that the automobile of but a few years ago was not what it was called, a horseless carriage, just as silly-looking a thing as the before-mentioned stage-coach of former days. How about the present-day delivery wagon? Just the horse left off. And the trucks? Human progress is not unlike the upbuilding of a coral reef, going on all the while, with many builders at work. This is hardly perceptible to the editors.

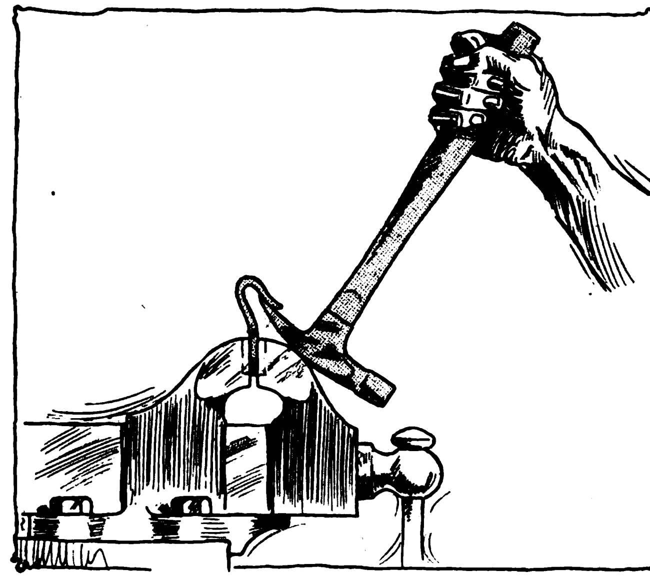

Fig. 7—Method which is more satisfactory than screw driver for opening hook

The trifling betterment of one design will help another to a new conclusion. Gradually, in a few years, unsightly will will become a matter of course—and the mighty editor will direct his attentions towards other matters.

New York City. B. BRITT.

Derivation of S. A. E. Formula

Editor THE AUTOMOBILE:—I would very much like to be enlightened on the S. A. E. formula for horsepower.

As I understand it, it has been based on observations made at a lineal piston speed of 1,000 feet per minute. This brings in the consideration of stroke and, by using this factor, the formula may be used nicely to compare the probable power of various cylinder dimensions. However, I have not been able to find an explanation of its origin. I would like to know the steps in its derivation.

Decatur, Ill. F. M. VAN DEVENTER.

—THE AUTOMOBILE has previously published the derivation of this formula, but since it is a matter of common interest, as many states use the formula as a basis of the calculation of horsepower in deciding the license fee, it will bear repetition.

The indicated horsepower of a four-cycle single-cylinder motor is equal to the mean effective pressure P times the area of the piston A, in square inches, times 1-4 the piston speed S in feet per minute and the result is divided by 33,000. The factor 1-4 holds good for the four-cycle motor since the power is only exerted on every fourth stroke or once for every two revolutions. This is expressed in equation form thus: $\text{I.H.P.} = \frac{P \times A \times S}{4 \times 33{,}000}$. Multiplying this by the number of cylinders N of the motor and further taking into consideration E, the mechanical efficiency of the motor, the formula for B.H.P. becomes: $\text{B.H.P.} = \frac{P \times A \times S \times N \times E}{33{,}000 \times 4}$ The A. L. A. M. assumed that the motor will deliver its rated horsepower at a piston speed of 1,000 feet per minute and that the mean effective pressure in the cylinder of the automobile motor will be 90 pounds to the square inch. It also assumed that the mechanical efficiency of the motor will be somewhere in the neighborhood of 75 per cent. and will average that figure. Substituting these values in the formula for brake horsepower and also substituting for A its equivalent $.7854\,D^2$, the equation reads: $\text{B.H.P.} = \frac{90 \times .7854 D^2 \times 1{,}000 \times N \times .75}{33{,}000 \times 4}$. Performing the indicated operations, the formula is simplified to its final form $\text{B.H.P.} = \frac{D^2 N}{2.489}$, or, in round numbers, the denominator may be called 2.5.

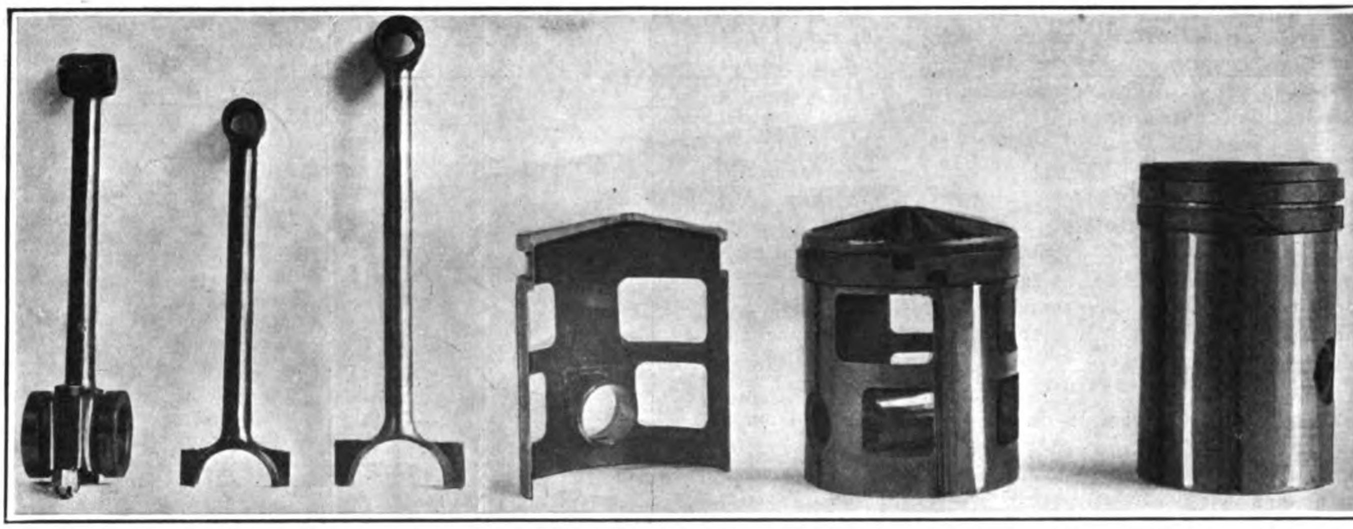

Fig. 1—Standard connecting-rods on Sizaire-Naudin   Standard steel BND racing pistons in Sizaire-Naudin

High Efficiency in New French Motors

Koecklin Motor Employs Combination Sleeve and Piston—Sizaire-Naudin and Alcyon Other Examples

THE two-cycle motor is receiving more attention in France today than it has for several years; in fact, it is being seriously considered in many circles. The two-cycle motor that is in the public eye today is very different from that exploited in America several years ago in that simplicity is not the only keynote. Rather, efficiency is placed in the foreground and simplicity is used only as it aids in efficiency. One of the latest French products is the Koecklin, a design of Alfred G. Koecklin and a type which has been well tried out, a motor of this design having competed in the recent Grand Prix race. Figs. 3 and 4 give the general scheme of this motor, which, is a combination two-cycle, sliding-sleeve design, but which differs from all previous motors of this style in that the sliding sleeve E1, Fig. 4, is an integral portion of the piston P. The sleeve has two sets of ports which extend practically throughout its circumference. The upper E serves to release the exhaust through the opposite passages E1, and the lower ports I admit the intake gases. The piston is a differential type, the small-diametered upper portion constituting the working piston and the large diameter lower part serving as a pump to suck the mixture into the annular space A on the downstroke, and deliver by means of the rotary distributor, or valve D, through ports I in the combustion chamber.

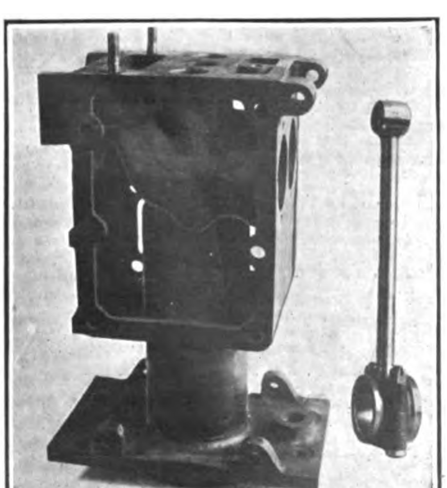

Fig. 2—Steel cylinder casting and connecting-rod of Sizaire-Naudin racer

The inventor claims by this design to have obtained an efficiency heretofore unknown with two-cycle motors, and in one size, namely 3.3-inch bore and 5.9-inch stroke, the motor developed 110-horsepower in its official tests. The four cylinders constitute a block casting of simple design. At the front end are two magnetos driven off a cross-shaft, and on the rear end of the crankshaft is a pinion driving the distributer valve through a silent chain. Thus the only meshing pinions on the motor are those driving the magneto. The crankshaft is carried on six S. K. F. ball bearings, there being a bearing between adjacent cylinders, one at fore end of shaft and two at fly-wheel end.

The motor is lubricated under pressure to all parts, the crankshaft being bored for the delivery of oil to the connecting-rod ends and the flow being directed through a tube on the connecting-rod to the wristpin.

In this motor, the crankcase compression generally utilized in two-cycle designs is not required, owing to the lower piston forming a pump which literally forces the fresh gases into the base of the cylinder and these in turn literally force the exhaust gases out of the upper portion of the cylinder.

Novel Sleeve on Koecklin Motor

The main feature of the Koecklin motor is the combination of a sleeve with the piston. The piston P has a tubular extension P I and on this sleeve or tube are two series of ports for the passage of respectively the fresh and the spent gases. Unlike that now familiar type of motor, the Knight, the fresh gases are not admitted through openings on one side of the sleeve and the exhaust gases expelled through openings on the opposite side. All the openings I on the lower plane serve for the intake, and all those E on the upper plane for the exhaust. Obviously, therefore, intake and exhaust take place all round the cylinder, and a complete view of the motor would show intake and exhaust pipes on both sides. Fig. 3 shows the piston at the end of its down stroke, and, as will be observed, the upper series of openings E on the sleeve coincide with the exhaust ports, and the lower series of openings I with the intake ports. The fresh gases rushing in at the base of the cylinder drive out the exhaust gases through the ports in the head, without any dead gases remaining, and with a practically complete filling of the cylinder. Fig. 3 shows the cylinder at the commencement of the firing stroke. It will be noticed that a rotary distributer D is carried between the carbureter and the reserve chamber of compressed fresh gas. This distributer gives admission from the carbureter to the lower diameter A of the cylinder, allowing the gas to be aspired, and on closing communication with the carbureter causes the gas aspired and compressed in the lower end of No. 1 cylinder to be admitted to No. 2 cylinder. This chamber is common to two cylinders, and, being heated by the water in circulation around the cylinders, there is no possibility of the condensation of gasoline on its walls.

The sleeve combined with the piston is in direct contact with waterjacketed walls throughout its entire length. This can be best observed in the drawings of the 3-liter motor built for competition in the French Grand Prix. The spark-plug 2 is set in a deep well, being placed in the centre of the head of the cylinder with water space all around, so that, while the piston has a water-jacket around it, only the sleeve is in contact with water-cooled surfaces on both sides. Two compression rings R are fitted just below the head of the piston, two R I at the base of the sleeve just above the intake ports, and three R2 at the base of the detachable head.

Other 3-Liter Motors of High Efficiency

The Sizaire-Naudin and Alcyon are two other examples of high-efficiency 3-liter motors in which some interesting details of construction are worked out. The Sizaire has cylinders of 3.07-inch bore and 6.1-inch stroke cast separately. Fig. 5 shows one of these cylinder castings. When the four castings bolt together they form a continuous waterjacket, the bolts passing from end to end, holding them together. These motors have run up to 101 horsepower at 2,000 revolutions on the bench, which is a piston speed of over 3,000 feet per minute. The normal running speed is 2,600 revolutions per minute when 80 horsepower is generated. The pistons are steel types, Fig. 6, comparatively short with one very broad rim at the top and the majority of the piston wall cut away with large rectangular perforations. In contrast with these special racing pistons is shown the standard Sizaire piston at the right in Fig. 6, which is much longer and uses two compression rings. Fig. 7 shows the standard connecting-rods used in the Sizaire cars at the left and the special rods for racing purposes at the right.

The valves, which have a diameter of 55 millimeters for a cylinder bore of only 78 millimeters are mounted horizontally near the end, there being two exhausts side by side on one side of the motor and two intakes on the opposite side. There are, however, only four cams on each camshaft, and, consequently, four push rods on each side. Each rocker, however, has two arms, one for each of the pair of valves. On the exhaust side, the valve springs are external and the exhaust gases are expelled vertically. Each valve is mounted in a cage, and, while the intakes are the same in design and size as the exhausts, their springs are contained within the intake manifold. To dismount an intake, four nuts have to be taken off and the complete valve with its cage can be withdrawn.

Two Models, 44-50 and 34-40, Latter of Which Has Been Re-Designed, and Is a Duplicate of Larger Model

THE Abbott-Detroit announcement for 1913 conveys the information that two models will be on the market for the coming season. These are to be known as models 44-50 and 34-40, the figures representing the horsepower ranges on block tests. For this year, the company made two models which were designated as 30 and 44, the latter being nearly the same mechanically as the larger 1913 model, but the smaller being very different from the new 34-40. In fact, the two models for the coming year are mechanical duplicates, the 34-40 being smaller in its various dimensions and having less power, but at the same time presenting the same appearance and mechanical design throughout. In order to bring about this similarity of the two, the small car had to be entirely re-designed, and is so different from the 30 of 1912 that it is considered a new car entirely, and its predecessor is looked upon as extinct. The unit power plant idea is carried out in both motors, flywheels, clutches and transmission gears being housed in cases which are made a part of the engines by being bolted to the rear of the crankcases.

Thus, both machines now use the same type of rear axle, both have Continental engines and their general chassis arrangements are alike.

Aside from the bringing of the two models to the same design characteristics, the most notable changes in the line are the adoption of an electric self-starting system, and the underslinging of the springs, front and rear, on both models. The latter feature has been incorporated to lower the center of gravity and leave the road clearance unaltered at 10 3-4 inches.

Description of Electric Starter

The electric starter is of Abbott design and consists of a motor mounted in a cylindrical case at the left forward side of the engine. This electric motor is independent of the lighting generator and the magneto, is driven by a storage battery and when in the operation of starting, is connected with the crankshaft through a train of gears. By making the starting motor a separate and distinct unit, the company believes that it has obviated all possibility of interference with the ignition and lighting systems through the failure of any one unit to perform its functions. The gear train between motor and crankshaft runs in a bath of oil. The crankshaft gear is mounted on an overrunning clutch which allows the gear to idle when not required for starting. Electrical connection between the electric motor and storage battery is made direct through the spark lever which makes the connection when the lever is retarded to a certain point. The spark lever automatically returns to its proper running position when released after the engine is started. At no time can the starter be operated unless the spark is fully retarded, which, under all ordinary conditions, would make it impossible to get a back-fire. In case of an unusual condition there is a protecting device located in the over-running clutch which will take a back fire caused by any trouble such as improper magneto setting or premature combustion due to carbon or other agencies, and will prevent such back-fire from damaging the starter or its parts. To start the motor, then, it is only necessary to bring the spark lever to its extreme retard position and to release the lever after the engine is running.

The 44-50 engine has cylinders cast in pairs, while the 34-40 is a monoblock-cast type. Cylinders are of the L-head design, their dimensions being:

Model	Bore, Inches	Stroke, Inches	A. L. A. M. Ratio	Horsepower	Piston Displ., Cu. In.
44-50	4½	5½	1.22	32 4	340.7
34-40	4⅛	5¼	1.27	27.2	280.6

Valves Are All On One Side

Inlet and exhaust valves are on the left; they have nickel-steel heads and machined steel stems. The two parts are electrically welded together and exhaust and inlet valves are interchangeable. The ends of all stems are hardened to protect them against excessive wear, and they are fitted with oil tempered springs. All valves, springs and stems are completely inclosed, there being two cover plates on each motor. Crankshafts and camshafts are carbon steel, heat-treated drop-forgings with a tensile strength of 90,000 pounds per square inch. The engines on both models are fitted with three crankshaft plain bearings of the following sizes:

Model	Crankshaft Diameter	Crankshaft Bearing Lengths
44-50	1⅞ inches	3, 3 11/16 and 4½ inches
34-40	1¾ inches	2¾, 3 and 4¼ inches

Bearings are all of Hoyt's nickel bronze. Flanges F, Fig. 4. are provided to take any end thrust which may be imparted from the clutch or from any outside mechanism.

The camshafts have integral cams. The steel is of the low-carbon analysis. The shafts revolve on Hoyt's bearings of nickel bronze, lubricated by oil which collects in pockets cast in the crankcases. Removal of the gearcase cover allows the easy withdrawal of the camshaft. The camshaft bearing sizes for both motors are 2 1-4 by 2 1-2 inches, 2 1-4 by 2 1-4 inches and 2 1-4 by 1 1-4 inches for the front, center and rear, respectively. Push rods, which are of the mushroom type, of crucible steel, bear directly on the cams.

Pistons are of the same grade of reverberatory air-furnace iron as that used in the cylinders, each being fitted with four diagonally split rings of the eccentric type, having a width of 1-4 inch. Five oil grooves are turned on the outsides to aid in the distribution of the splashed oil to all parts of the piston bearing surface. Pistons have a length of 5 1-2 inches in the 44-50 motor and 5 inches in the 34-40. Wristpins are of seamless steel tubing, pinched into the small ends of the connecting-rods, making them solid with the rods, the bearings being in the piston bosses. By this arrangement, the bearings are made longer, the total length of wristpin bearing in each piston being 2 7-8 inches, and the diameter being 1 1-4 inches for the large type and 1 inch for the small model.

Connecting-rods have a length of 11 inches in the 44-50 motor and 10 1-2 inches in the 34-40. Their lower bearings are 1 7-8 by 3 inches and 1 3-4 by 2 1-2 inches, for the two sizes of motors. These connecting-rods are of the universally used, tapering I-beam construction, made of 0.12 to 0.15 per cent. carbon steel, drop-forged and heat treated. Connecting-rod caps are held in place by nickel-steel bolts, four being used for each rod end. They are locked in place, connecting-rod bearings being adjusted by means of sheet steel shims of varying thickness.

The flywheel is fastened in the usual way to the crankshaft by means of a flange and six large bolts. The diameter is 17 1-2

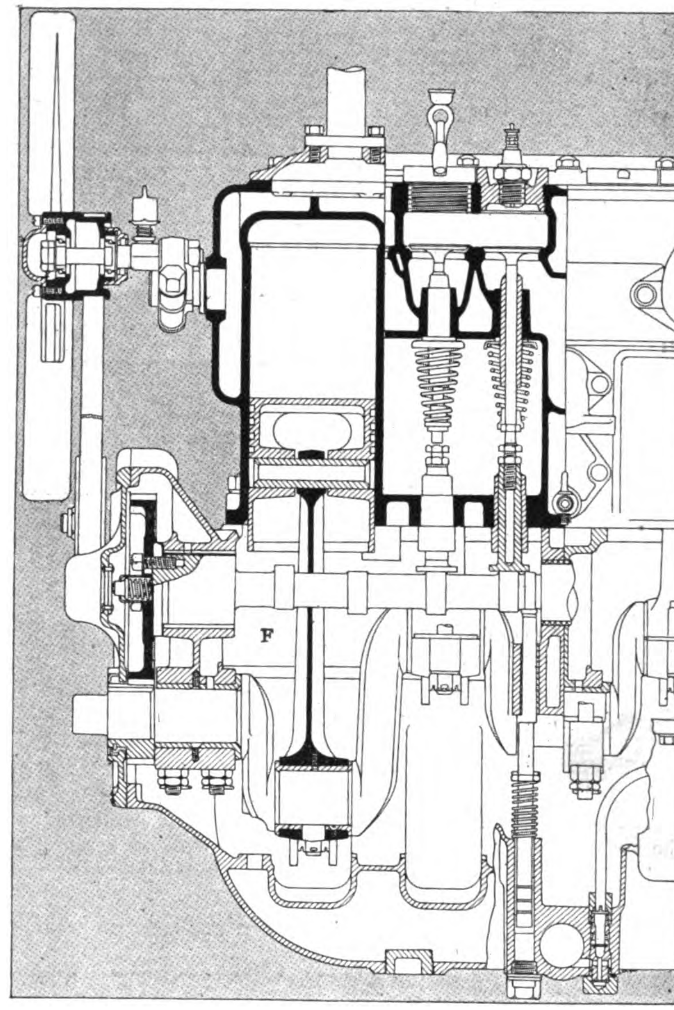

Fig. 4—Sectional view through cylinder of the Abbott motor

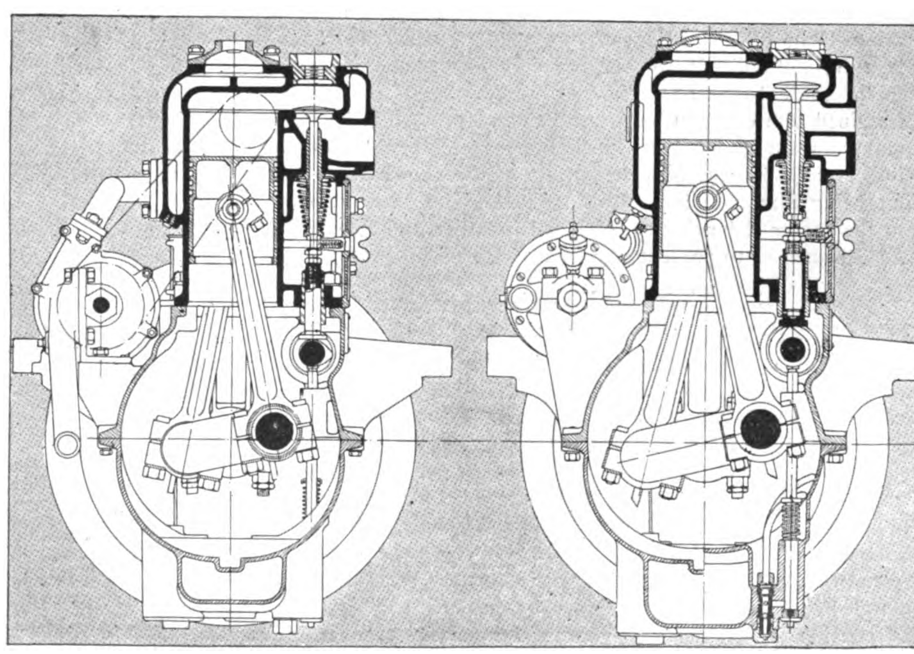

Fig. 5—Transverse section through Abbott 34-40, left, and 44-50, right

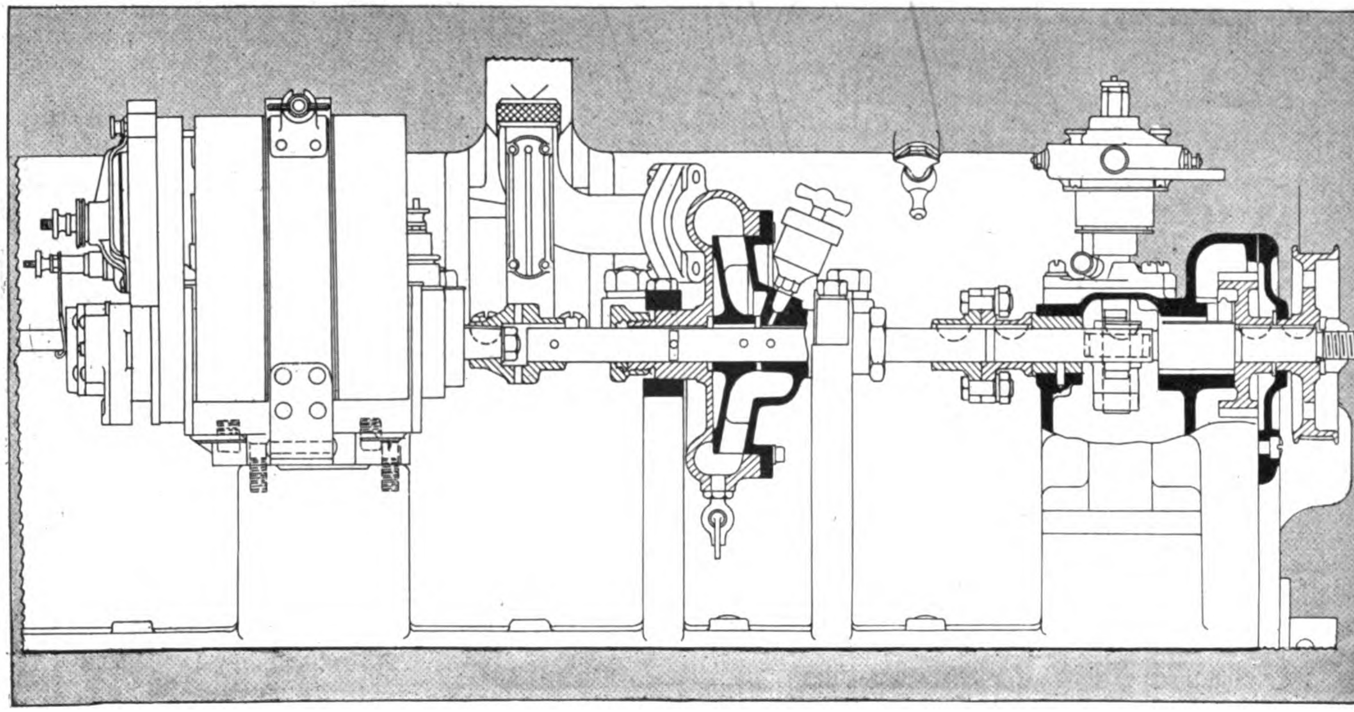

Fig. 6—Magneto and motor pump shaft are mounted on the right side of the motor

inches and the face width 5 inches for either type of engine.

All timing gears are helically cut on automatic hobbing machines, which process of manufacture tends to uniformity of teeth and to noiselessness. The gearset is housed in a case at the front of the motor, and consists of three steel gears and one cast-iron gear, the connecting-rod gear, idler gear and pump gear being of steel and the camshaft gear of cast iron.

Crankcases are made of an aluminum-nickel alloy and they are of the two-piece construction, all bearings being carried in the upper halves. The lower portions contain the oil reservoirs, and are made easily removable for accessibility of bearings, connecting-rod ends and crankshafts. The four supporting arms are integral with the upper half of the crankcase, two located in front and two in the rear.

Lubrication is by the constant-level splash system, with oil circulated by a double plunger pump, cam-operated from the camshaft. This pump forces one stream of oil over the timing gears in front and a second stream over the rear crankshaft bearing. The other bearings of the engine receive their oil by splash from the dipping of the connecting-rod ends into the oil troughs, there being an individual trough the oil in which is maintained at a constant level at all times, for each rod end. Oil from the troughs and that which flows from the bearings and cylinders finds its way into the bottom of the crankcase, whence, after being filtered it is again circulated. The lubricant is put into the motor through the combined breather and filler, which is so designed as to prevent any leak of the oil.

Three Units in Electric Apparatus

Water circulation is assured through the use of a gear-driven centrifugal pump mounted on the pump-and-magneto shaft between the magneto and the lighting generator. The pump and its paddles are bronze castings. The fan is a one-piece, pressed-steel construction, 18 and 16 inches in diameter for the 44-50 and the 34-40, respectively. The single wide water outlet manifold connection is at the top of the monobloc motor, while the larger engine is provided with two outlet connections, one for each pair of cylinders.

As already mentioned, the electrical apparatus consists of three separate units, one to perform each of the functions of lighting and starting the engine and igniting the cylinder charges. The last is accomplished through the use of a Splitdorf dual magneto, while an Auto-Liter generator, which is driven by silent chain from the pump shaft, furnishes the current for lighting all lamps. The starter-motor is independent of the other two pieces of electrical apparatus, and is mounted on the opposite side of the power plant, Fig. 3.

Mayer carbureters are used, the sizes being 1 1-4 inches and 1 1-2 inches on the two models. Carbureter adjuster and priming device are placed on the dash within easy reach of the driver. Gravity gasoline feed is from a 11.6-gallon tank on the 34-40 and 16.7 gallons on the 44-50. The 44-50 roadster carries 30.1 gallons with a reserve of 3 gallons and the 34-40 roadster 34 gallons, with a reserve of 2.1. Gasoline tanks are fitted with self-measuring gauges.

The clutch has fourteen disks, alternate sets being faced with Raybestos. The disks run dry. The gearset furnishes three forward speeds, the gearshift lever being mounted at the right, and the shift accomplished through the use of an H-gate. The gears are of chrome-nickel steel, and the shafts and broaches are of 3 1-2 per cent. nickel steel throughout. Gear shafts are mounted on Timken bearings.

The propeller shaft uses two Spicer universal joints and a

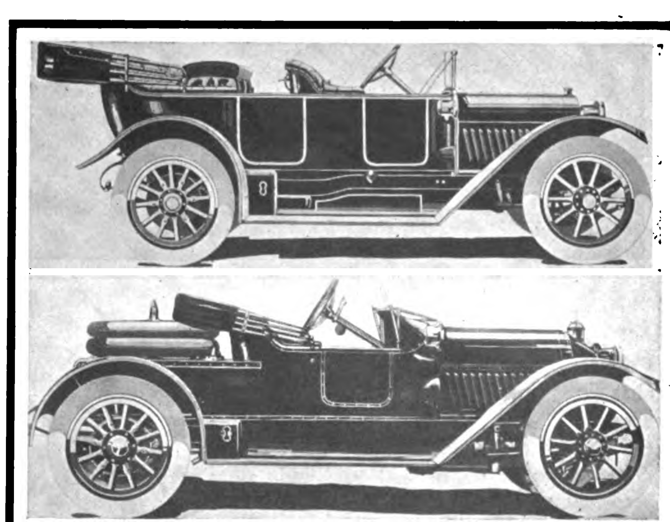

Fig. 7—Abbott-Detroit 44-50 seven-passenger touring car
Fig. 8—The 1913 Abbott 44-50 battleship roadster type

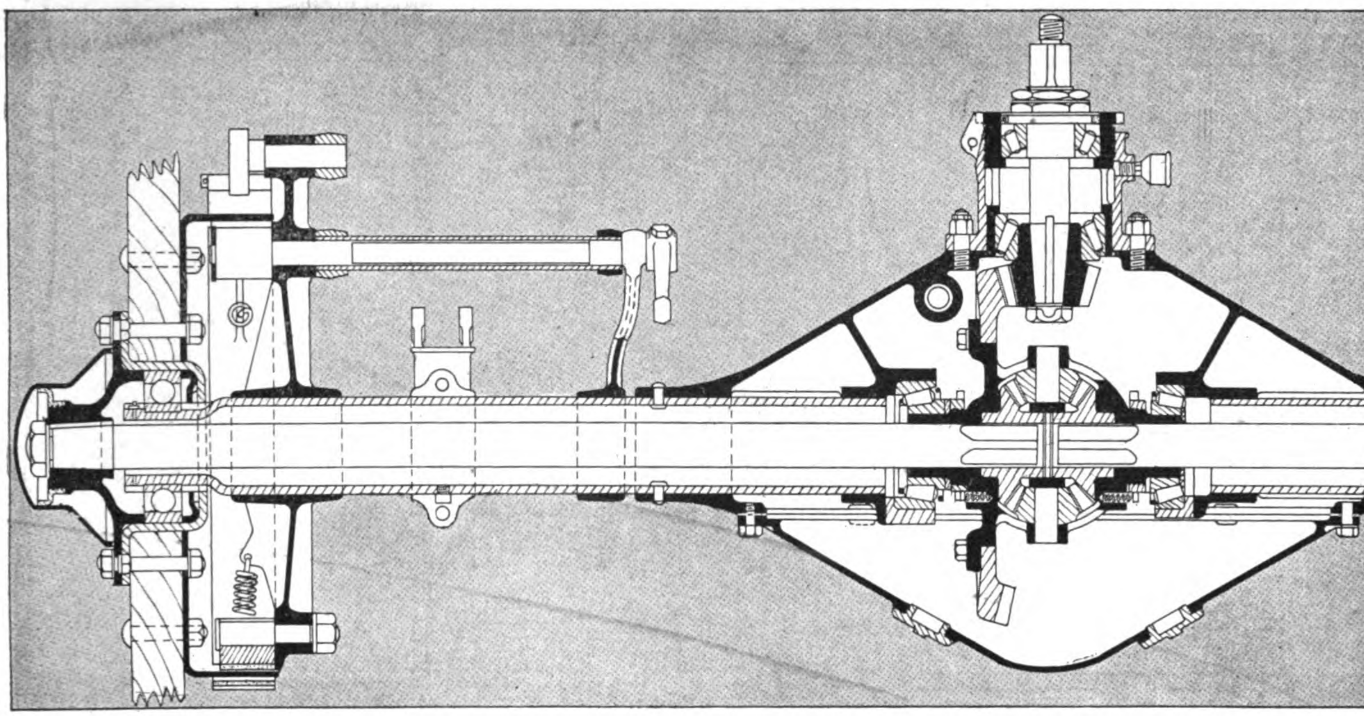

Fig. 9—View of rear axle on Abbott 1913 cars, showing differential brakes and wheel bearings

tubular, two-piece torque arm extends from the center cross-member to the differential housing. The side radius rods connect from a position half-way between gearbox and differential to the rear axle housing.

The rear axle is of the floating type and made amply strong. Shafts and gears are nickel steel and the radial and thrust loads of the rear wheels are carried on Shafer annular ball bearings. The pinion shaft, as well as the differential casing, is provided with Timken bearings. The differential housing has no flanges or webs, being considered amply strong without this feature. The differential is of the bevel type with nickel-steel gears. An assembled view of the rear axle used, as well as of the differential gears and pinion, is shown in Fig. 9. The front axle is of the conventional one-piece I-beam construction, the wheel spindles carrying Timken bearings. Steering knuckles are made of the same material as the axle, which is bowed in the center with a drop of 4 inches.

Brakes are 16 inches in diameter for 44-50 and 14 inches for the 34-40. They are internal expanding and external contracting lined with a friction-proof material. Drums are pressed steel and bolt directly to the rear spokes. An equalizing arrangement is placed in all brake connections. All working parts and bearing surfaces are provided with grease-cups.

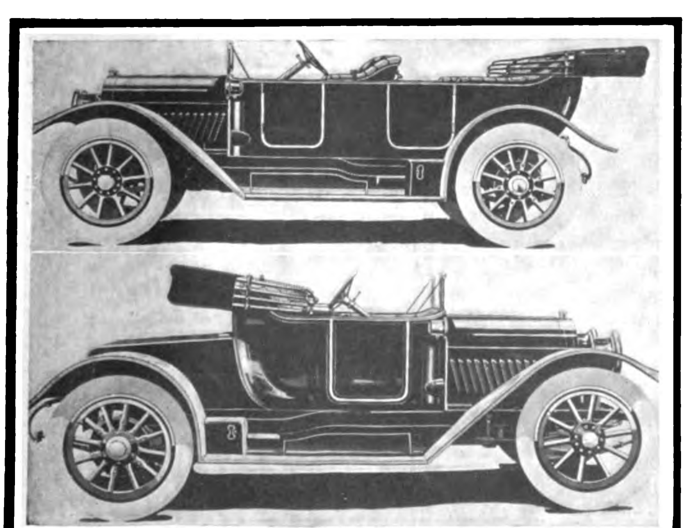

Fig. 10—34-40 Abbott-Detroit touring car
Fig. 11—34-40 three-passenger roadster type

The frames of the two models are practically of the same construction, there being a drop just to the rear of the gearset and a kick-up in front of the rear axle. The side-members are of channel section 4 inches in width with a depth of 1 1-2 to 3 1-4 inches.

Springs Identical on Both Models

Springs are practically the same on both models and are underslung. The rear ones are three-quarter elliptic, 48 inches long and 2 inches wide on all models. Front springs on the 44-50 are semi-elliptic, have a length of 38 inches and the same width as the rear springs. The front springs on the smaller car, while they are of the same width are 1 inch shorter. All spring bolts are provided with integral grease-cups.

Spokes of the wheels undergo a special oil treatment which is claimed to preclude any possibility of looseness and any decay due to water and weather. Wheel and spoke dimensions are as follows:

Model	Wheel Diameter	Spoke Diameter	Number of Spokes Rear	Front
34-40	34	1¼	12	10
44-50	36	1¼	12	10

Six most attractive body designs are offered. Limousines, seven-passenger touring cars, demi-tonneau models and a fore-door battleship type roadster may be had on the 44-50 chassis, while a five-passenger touring car and a three-passenger fore-door roadster are mounted on the smaller model. The price on the latter two is fixed at $1,700, while the cost of the other models ranges from $1,975 to $3,050. The Abbott-Detroit limousines are made in Berline and cab-side styles. The bodies are of metal and the rear compartments are finished in whip-cord and broadcloth. Fittings are all blackened nickel and the dashes are faced with leather. Some lights are also fitted. The touring cars have been altered somewhat and their lines have been made more rangy and sweeping. Ventilators have been placed in the sides of the hoods, while full equipment, such as robe-rails, foot-rails and the like are furnished. The roadsters are of two types, these being the 34-40 and the battleship model, which has a V-shaped radiator. This was brought out in January last and has been very successful. The body construction of the car is of sheet steel with rows of rivets showing.

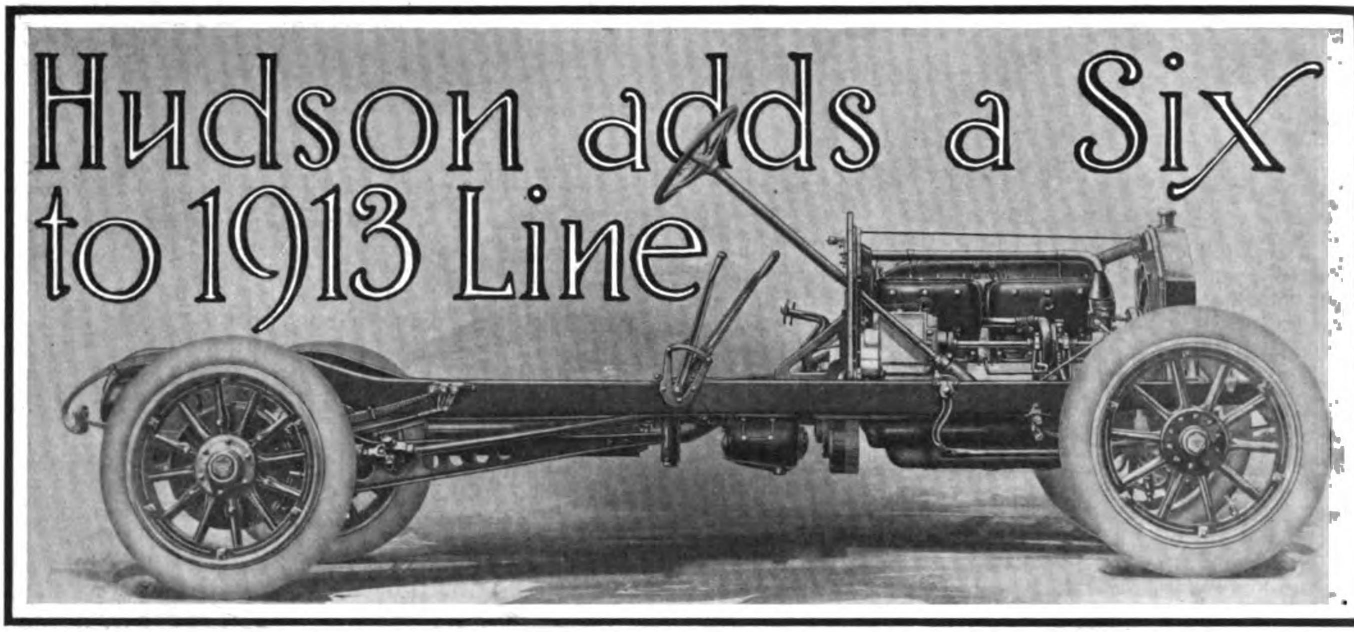

Fig. 1—Side view of the Hudson 1913 six-cylinder chassis

The New Car Will Be Known as Model 54, and in Many Respects Resembles the Four-cylinder Type

THE Hudson Motor Car Company has entered the six-cylinder field, this fact being conveyed in their announcement of an entirely new model, called the Hudson 54. It is in all respects a larger edition of the Model 37, announcement of which was made in the issue of July 11.

The motor is of Continental make; its general characteristics are comparable with those of the motor used on the 37. The powerplant is of the unit type, the gearset being bolted directly to the upper half of the crankcase. Cylinders are cast in blocks of three and the bore is 4 1-8 inches; stroke 5 1-4, cylinder dimensions being the same as those of the four-cylinder model. These figures give a stroke-bore ratio of 1.27. The horsepower rating, according to S. A. E. formula, is 40.8, but dynamometer tests show 54 horsepower at a speed of 1,500 revolutions per minute. The cylinders are of the L-head type, all valves being located on the left side, Fig. 2. These are interchangeable and have a diameter of 2 inches and a clear opening of 1 3-4 inches. Valve stems and springs are inclosed in dust-proof casings which augment the motor silence and protect the valve mechanisms against dirt and grease. There is a removable plate A, Fig. 2, over these valves for each block of three cylinders. The pistons are of gray iron and are made extra long so as to distribute the side thrust and to reduce the wear as far as possible on both the pistons and cylinder walls. The wristpins are pressed into the piston bosses and are held in place by studs of nickel steel which are prevented from working loose by cotter pins.

Details of Shafts and Bearings

The connecting-rods are of conventional I-beam sectional type; drop-forged and heat treated. Connecting-rod ends are fitted with specially designed caps, each secured by four nickel-steel bolts and castellated nuts. In case of wear, thin shims are placed between caps and connecting-rod bearings. The crankshaft has three bearings and it is of very substantial construction, well balanced. Its bearings are of bronze, lined with nickel babbitt. The camshaft is also of special steel, hardened and ground, and the cams are made integral with it. To avoid deflection in lifting the valves, the camshaft bearings, which are three in number, are made extra large. These are also of nickel babbitt. The tappets, which bear on the cams, are of the mushroom type and are in contact with the cams at all times. The dimensions of the various bearings are given below:

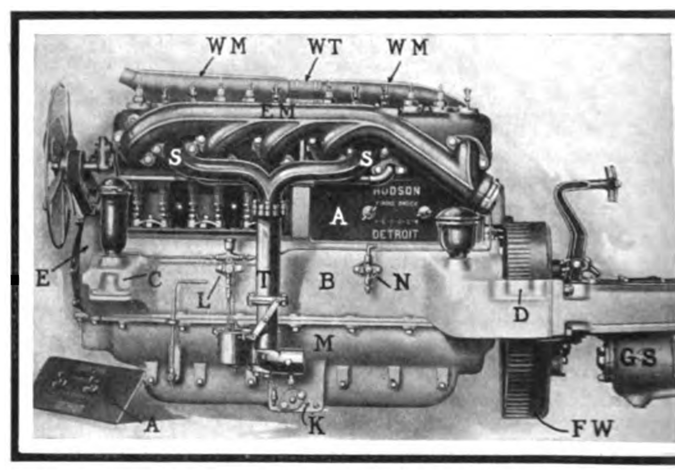

Fig. 2—Left side of six-cylinder Hudson motor

	Front Bearing	Center Bearing	Rear Bearing
Crankshaft	2 x 2 9/16 in.	2 x 3 in.	2¼ x 2 15/16
Camshaft	2¼ x 2⅛	2¼ x 1⅛	1⅞ x 1¼

The connecting rod bearings are 2 x 2⅝ inches and the wristpin bearings 1 1/16 x 1⅞ inches.

Cooling and Lubricating Features

As in the usual construction, the crankshaft bearings are bolted to the upper half of the crankcase B, Fig. 2, which is of an aluminum alloy and made very rigid. At its front end, the upper half of the crankcase has two integral arms C one at either side which fasten the motor to the frame, while the two rear hangers D are made a part of the arms which pass around the flywheel and to which the gear-box arms are bolted. The timing gears are in the usual position at the front of the motor and they are housed E against oil leakage. The gears are of the helically-cut variety and they run in oil, which adds to their silence and increases their efficiency. The water pump F, Fig. 3, of the centrifugal type, is mounted somewhat forward and is the same type as that used on the four-cylinder Hudson motor. It is mounted between two bearing hangers H which are integral with the upper half of the crankcase. Aside from carrying the water pump, these hangers serve to stiffen the pump and magneto shaft, J. By this mounting the glands can be packed or the pump removed without interfering with the other members of the power plant.

As will be seen from Fig. 2, the water outlet manifold connections are extremely large and of unique construction, extending over the entire top of each block of three cylinders, and the two being connected by rubber tubing WT. The exhaust manifold EM has six connections with the motor, four of which are uniform, while the last two come from the manifold in a peculiar way, due to the downward slope of the manifold. This downward slope is necessary in order that the manifold will pass under the floor boards.

Like the four-cylinder motor this new Hudson Six is lubricated by a constant-level splash system with a reservoir in a sump K beneath the crankcase. This lubrication system, which is of the conventional type, makes use of a pressure-distributing, plunger pump, L, cam operated from the camshaft. The oil overflows from the individual oil troughs, one being provided for each connecting rod, and into the oil sump, K, at the bottom of the crankcase. Here it is filtered and then pumped up by the plunger pump, distributed to both front and rear bearings and then returned to the troughs.

Gasoline Tank on Rear of Frame

As on the four-cylinder car, the Zenith carbureter, M, is used. The fuel is fed to it by pressure from an air-pump, N, cam-operated. In order to aid in starting the motor in cold weather, there is an adjustment on the dash for shutting off part of the air entering the carbureter. The gasoline tank, T, Fig. 4, is placed in the rear of the frame, an innovation on the Hudson cars this year. This tank is hung on two strong leather-lined brackets, D, and has a capacity of 22 gallons. The air pump maintains a pressure of 2 pounds per square inch on the fuel contained in the tank and an air gauge on the dash indicates this pressure within the tank. The piping from the tank passes forward along the left frame member to the carbureter. There are two intake manifold connections, S, Fig. 2, with the cylinders, one for each block of three, a straight tube T passing vertically from the carbureter to the manifold flange. This vertical tube is water jacketed.

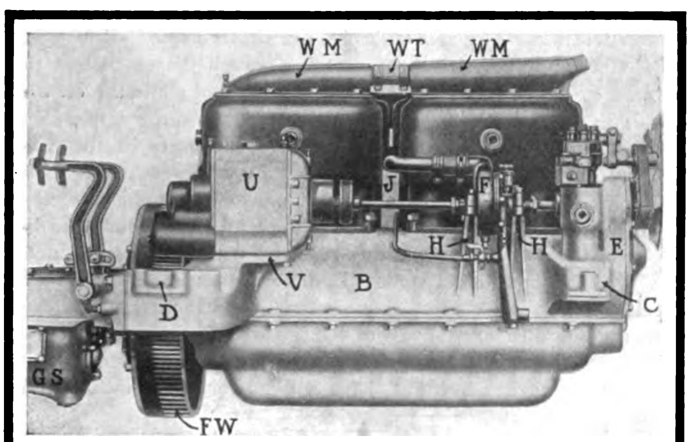

Fig. 3—Right side of six-cylinder Hudson motor

Electric Starter and Lighter

The Delco ignition, starting and lighting system is used on the Hudson six-cylinder motor, as well as on the four. The motor-generator is seen at U, Fig. 3, and is placed on the right side back of the water pump and next to the dash. A special bracket, V, has been cast on the upper half of the crankcase to hold this electrical unit. The system furnishes a dual ignition with magneto type of spark for ordinary running and storage battery current for emergency use. A kick switch on the dash controls the system. The firing order is 1, 5, 3, 6, 2, 4. The motor-generator, U, when used as a motor, draws current from the storage battery, which has a capacity of 80 ampere-hours. In starting the engine, pushing the starter button on the dash, in connection with throwing in the starter gears by pushing forward on the clutch pedal, completes the necessary operations. The pushing of this dash button sends current from the battery to the motor, and the gears being in mesh, the motor turns over the crankshaft until sufficient charge is drawn into the cylinders to cause the engine to operate on its own power. The periphery of the flywheel, FW, Fig. 3, has a number of teeth cut in it, as shown, with which the teeth of the starter gear mesh when the starting apparatus is brought into service. This use of the flywheel face is a part of the Delco arrangement and has been since its inception. When the starter button is released, the motor-generator becomes a generator and supplies current to the storage battery, which, when its capacity is reached, floats on the line and is ready to supply current either for lighting or for driving the electrical unit as a motor. All the lamps can be lighted directly from the generator or from the storage battery. A small lamp on the dash makes it possible to read the gauges at night. This dash lamp is in the same circuit with the tail lamp and should the latter go out for any reason, except the burning out of its filament, this fact will be indicated by the dash lamp being dark also. All the lights are electric, both side and head lights as well as the rear lamp, and the current for their operation is supplied by the generator which operates as such whenever the motor is running, and except when it is being used as a motor for starting.

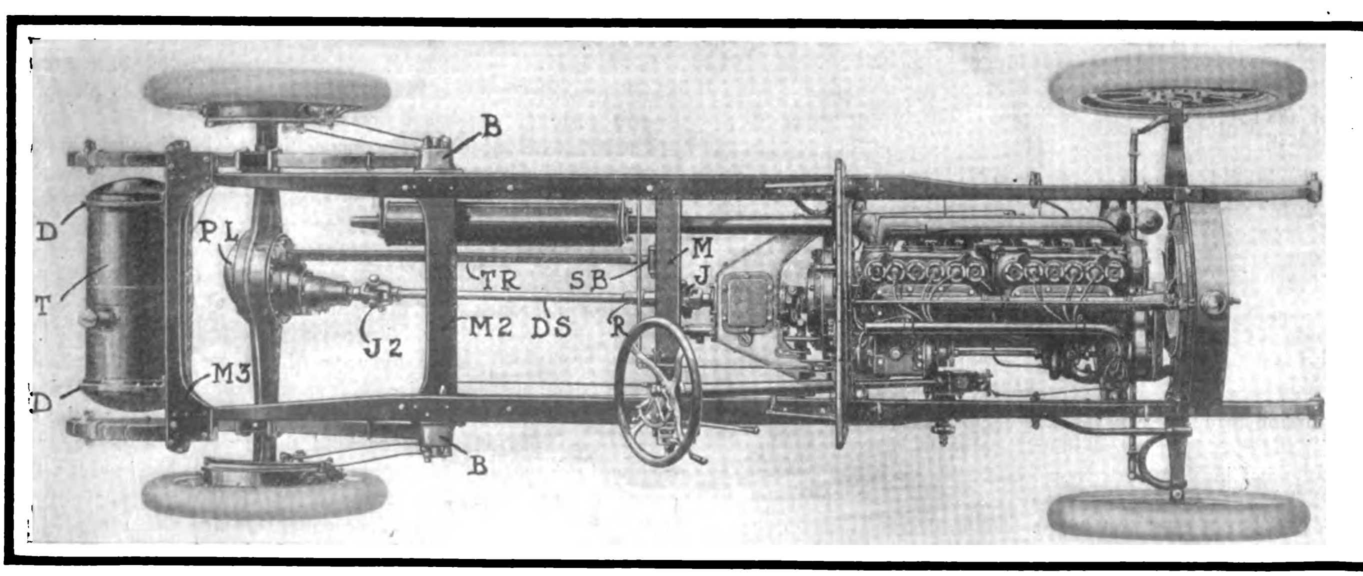

Fig. 4—Plan view of Hudson Six chassis, showing location of torsion rod to relieve strains on transmission shaft

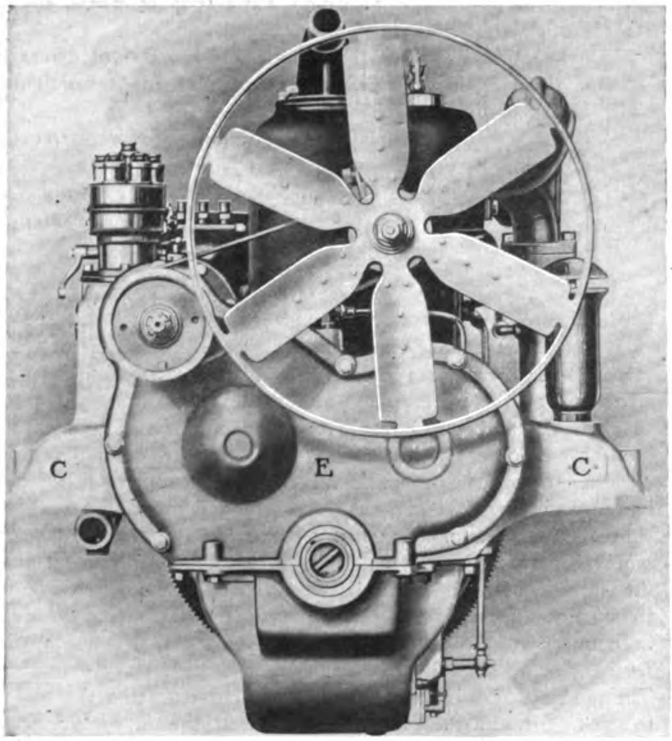

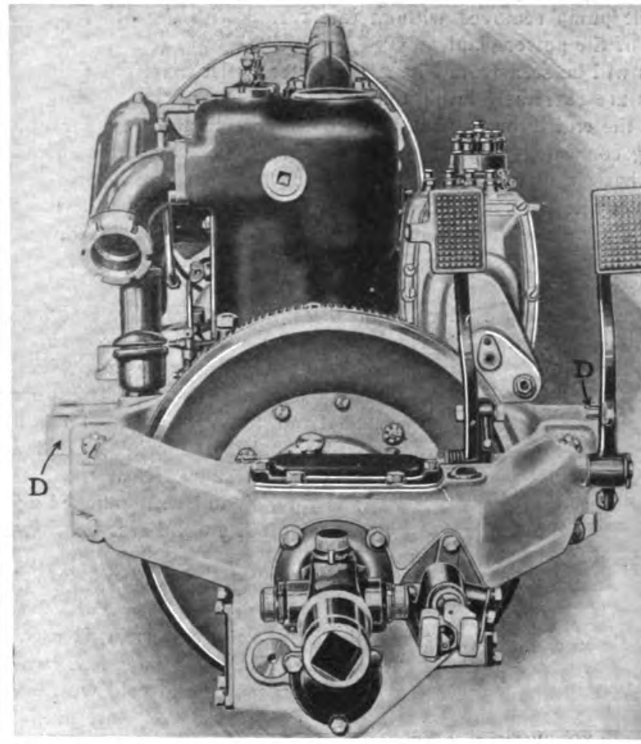

Figs. 5 and 6—Front and rear views of the motor of the Hudson Six, showing supports of motor

The clutch is of the multiple disk type, having 15 plates, 11 inches in diameter. The driven disks, of which there are 8, have cork inserts. The entire clutch runs in oil and is contained in an oil-tight case which is a part of the flywheel. The clutch spring is located in a hole bored in the end of the crankshaft and the pressure is transferred to the clutch drum through a ball thrust bearing. In order to facilitate the separation of the steel disks when the clutch is released, small springs are placed between these disks. A plugged hole in the clutch casing is provided for use in cleaning the clutch parts and for lubricating them.

The gearset, GS, Fig. 2, which is bolted to the rear of the motor in a V-shaped frame, as seen clearly in the top and bottom views of the chassis, is of the three-speed, selective type, direct drive on third. Gears have a wide face and are made of special hardened steel. Large roller bearings, mounted in malleable iron cages, are used throughout the gearset. The gearbox is made oil tight to prevent the leakage of the lubricant in which the gears run.

The drive shaft DS, Fig. 4, is provided with two universal joints, J1 and J2, similarly placed to those on the four-cylinder model. One universal, J, is just back of the gear-box and another, J2, at the rear axle housing. The drive shaft is of nickel steel and heat treated. The front end of the shaft is squared and slides in the front or transmission universal joint, to allow for any differences of relative position of rear axle, due to unevenness of road surface.

Rear Axle Same as on Four

This sliding square, R, has a width of 1 3-8 inches and a length of 5 1-2 inches and is smooth finished, hardened and polished. A torsion rod, TR, runs parallel to the propeller shaft from the center cross member of the frame M, to the rear axle. This torsion arm TR relieves strain from the end of the transmission shaft and universal joint. Its front end is held by the cross member in a double spring buffer, SB.

The rear axle is of the same type as that used on model 37, and is of pressed steel and floating. The driving gears and differential are mounted as one unit, which is bolted to the axle and removable without taking the whole axle down, due to the floating construction. The rear axle driving shafts are of oil-treated nickel-steel and they drive the wheels through flanges bolted to the wheels. The driving pinion is of nickel steel while the crown gear is of specially hardened machine steel. A large removable plate PL in the rear admits of access to the parts of the differential. The rear wheels are carried on roller bearings, two for each. All wheels are of artillery type, spokes having a diameter of 1 3-4 inches, 10 spokes being used in the front wheels and 12 in the rear. The wheels are fitted with 36 by 4 1-2-inch tires with demountable rims. Both brakes are on the rear wheels the service brakes being external contracting while the emergency brakes expand from the inside. The brake drums, which are of one-piece, pressed-steel construction, and which fasten to the spokes by bolts, have a diameter of 16 inches and a width of 2 inches.

Axle and Frame Construction Details

The front axle is of one-piece drop-forged, I-beam type, and at its smallest point is 2 5-8 inches high by 1 5-8 inches in width. It has the conventional bowed center. The wheel spindles are of special steel and carry large roller bearings on which the wheels are mounted. Each spindle has two phosphor bronze bushings which are pressed into place.

The frame is of channel construction. The channels have a depth of 4 1-2 inches and a width of 3 1-4 inches, the metal being 5-32 inch in thickness. The side members are narrowed in front to allow for a small turning radius and a raise of 4 1-2 inches is made at the rear, permitting of the lowering of the center of gravity as much as possible, and at the same time giving ample clearance over the rear axle. The cross members M, M2, M3, Fig. 4, which are also of pressed-steel channel, are very substantial; M is just at the rear of the gear-box, the second, M2, half-way between this and the rear of the frame, and the third, M3, to which the gasoline tank, T1, is fastened, at the extreme rear. Its extension to hold the upper ends of the rear springs is shown in Fig. 4. The cross member M2 is given this position to aid in the supporting of the front spring shackles B1 of the rear springs. The brake equalizers are also mounted on this cross member M2 and the rear brakerods pass from it to the brakes, as shown, Fig. 4. Rear springs have a 3-4 elliptic construction and their leaves are very thin and wide, and are made of oil-treated steel. They are tongued and grooved to prevent side motion, this also being further guarded against by the use of leaf retainers. All spring eyes are provided with phosphor-bronze bushings to prevent squeaking and wear. The spring shackles are drop-forged, while the suspension bolts are of steel, hardened and ground, and provided with grease cups. The spring sizes are as follows:

	Length	Width
Front springs	37 inches	2 inches
Rear springs	50 inches	2 inches

The wheelbase is 120 inches and the tread 60 inches.

Bodies which are provided on the new six are of sheet-steel of most distinctive design and may be had in either five-passenger touring car, five-passenger torpedo, two-passenger roadster, seven-passenger touring car, limousine or coupé types. The regular equipment consists of speedometer, dashboard gasoline gauge, demountable rims, windshield, mohair top with envelope and side curtains, and the usual complement of tools. This is in addition to the electric system already mentioned.

The body design is of exceedingly rangy appearance, the cowl being deep and having a low slope. Upholstery is 12 inches in depth of hand buffed leather, and the dash is also covered with leather, a feature which several of the makers have incorporated in their newest body designs. The doors have been made specially wide to permit of easy access to all seats, and door handles are within. The new six, in fact, comes up to the Hudson standard of mechanical and body construction in every way.

Right or Left Control—Which?

(*Continued from page* 213)

door of the car from the left side for the passengers. In the selling season the branch disposed of 300 little-sixes with right drive.

Franklin—right-hand drive. The only advantage of the left-drive, according to the head of the Franklin agency, lies in the fact that it is safer to make a turn to the left between cross streets. Considerable talk has been made on the subject of taxicabs but the local agency is firmly in favor of the existing type of drive.

Winton—right drive. C. M. Brown, sales manager, says that there is less talk of left drive than there was last year. He cites the strain upon the driver's nerves in meeting another vehicle at speed in a narrow road; the danger of scraping the curb with the right front wheel and the unnaturalness of the position of the driver at the left as among the disadvantages.

R. C. H.—left drive. The advantages of the left drive in heavy traffic and elsewhere are too apparent to need detailed defense. Where there are traffic rules, the idea of forcing the passenger in a two-seated roadster to dismount in the street and walk around the car is all that is needed in the way of an argument. Such practice is positively dangerous at worst and uncomfortable at best.

Knox—optional. While the branch sold more right drives this season, the left drive is growing in popular favor, particularly with closed bodies.

Metallurgique—right drive. Little inquiry for left-drive cars.

Pope—right drive on pleasure cars and left on trucks. Inquiry for left-driven cars is appreciable but not pressing. The left position in the commercial wagons has proved a safeguard and a convenience in traffic.

National— left drive. W. C. Poertner states that the change from right to left drive in this line makes for comfort, ease and safety for driver and passengers. Only a few prospective customers have balked at the left drive and after a trial, practically all of these have been pleased with the change. Mr. Poertner is enthusiastic and predicts a sweep for the idea. His company also handles the Herreshoff line with left drive.

Many Inquiries for Left Drive

Peerless—Left drive on town cars. The use of the left drive has been welcomed by the customers of the Peerless company and the New York branch is enthusiastic for the innovation. The safety and convenience of the left drive for town cars in New York is the keynote of the position taken. Speaking about the inability of the driver to open the door of the car for passengers without alighting, the Peerless company says that the chauffeurs of its patrons should not open the door as that function is within the province of the footman who sits in the right seat or the doorman of the establishment which is being visited.

Lozier—the left drive. Delighted with the change. Wonder why it was not made before.

Packard—right drive. There is an increasing inquiry for left drive, particularly with reference to the town car. With the advanced type of self-starter and taking the tires from the running-board and placing them at the rear, the left drive idea is growing rapidly for automobiles to be used in town and suburban service.

Ford—left drive. The attitude of the factory in retaining the left drive and announcing a vastly increased production for 1913 is favorably reflected in the New York branch.

Abbott-Detroit—right drive. Not an inquiry for left driven cars except for coupé types has been noted for 3 months and not a prospect has been turned away this year because the company handled no left drive cars.

Chalmers—right drive. Only an occasional inquiry for left drives.

Moon—left drive to be announced. The right drive is popular with those who have had experience with it and the same may be said for the left drive. The left drive is convenient in traffic, particularly with the roadster type. With closed bodies the advantages are numerous. The 1913 cars will be constructed so as to give right drive if the customers wish it.

New Herreshoff six-cylinder, 36-horsepower touring car, with straight-line body design

Herreshoff Smallest Six

1913 Model, Just Announced, Will Sell for $1700—Left Drive and Center Control Features

A BABY six-cylinder touring car is soon to be put on the market by the Herreshoff Motor Company. This machine, which will be the smallest six yet manufactured in this country, will be made to sell for $1,700. The principal mechanical features of the car are its unit power plant, left-hand drive and center control, four-speed transmission, platform springs and three-point suspension.

The six-cylinder motor is rated at 36 horsepower, the bore being 3 3-8 inches, while it has a long stroke of 4 1-2 inches, giving a stroke-bore ratio of 1.33. The cylinders are cast in one block, and the design of motor and powerplant is such that its removal may be effected as a unit which includes clutch pedals, gear levers and brake controls.

The motor is of the T-head type, the exhaust valves being on the right and the intakes on the left. These valves are interchangeable, are mechanically operated from the camshafts and their stems and springs are completely inclosed by two removable cover plates. The valves have a diameter of 1 3-8 inches and a lift of 5-16 inch. Camshafts are 7-8 inch in diameter at the bearings, which are three in number. Their sizes follow:

Front camshaft bearing..............	⅞ inches by 3 inches
Center camshaft bearing............	⅞ inches by 2¼ inches
Rear camshaft bearing..............	⅞ inches by 2 inches

The cams are integral with the camshafts, which are cut from solid bars of high carbon steel.

The crankshaft is of ample proportions, it being a perfectly-balanced, one-piece forging and mounted on three bearings, the sizes of which are given below:

Front crankshaft bearing........	1½ inches by 2½ inches
Center crankshaft bearing.......	2 3/16 inches by 3 inches
Rear crankshaft bearing.........	1½ inches by 3½ inches

The wristpin, or upper connecting rod bearings have dimensions of 3-4 inches by 1 5-8 inches, while at their lower or crankshaft ends these rods have bearings measuring 1 11-16 inches by 2 1-8 inches. With all these bearing dimensions, the first figure applies to the diameter while the second gives the length. Throughout the motor, Herreshoff white metal bearings are used.

Pistons are of special iron and they have a length of 3 1-4 inches, this dimension being but 1-8 inch shorter than the diameter. The pistons are fitted with three diagonally-cut expansion rings of the eccentric type.

Cooling is accomplished by the thermo-syphon system, no water pump being used. The inlet and outlet water manifolds are of large proportions, there being but one connection to the cylinder casting for each, which arrangement is usually found with the conventional monoblock-cast type of engine. The cooling is aided through the use of a large fan, placed in the customary position back of the radiator. The water jacket space communicates around the entire six cylinders, due to the block casting. The jacket space has a width of 5-8 inch, while the jacket wall is 3-16 inch in thickness. The cylinder walls have a thickness 1-32 inch greater, or 7-32 inch.

Timing gears are placed at the front end of the motor and are inclosed in the usual way, the aluminum housing being proof against oil leakage. These gears are of the spur variety and have a width of 3-4 inch.

Crankcase a Herreshoff Idea

The crankcase is a one-piece construction of aluminum, the design of which involves a Herreshoff patent. The case extends back so as to take in the clutch, gear set and flywheel, thus carrying out the unit idea. The total length of the power plant from the front of the motor back to the end of the gear box is 68 inches, a surprisingly low figure considering that the motor is a six-cylinder one.

Splash lubrication is employed, there being an individual oil trough provided for each connecting rod. The lubricant from these crank pits overflows into an oil reservoir in the bottom of the crankcase, from which point it is drawn by mechanically operated plunger pump to the sight feed on the dash and thence forced forward to the timing gear case, serving the function of lubricating the timing gears as well as the motor bearings. From the gear case, the oil runs down again to the six connecting-rod wells.

A Stromberg carbureter is used with the new six, it being of the single jet type, fed by gravity. This carbureter has an auxiliary air valve fitted with two adjustments. There is also a shut-off valve in the primary air tube, which is closed for starting the motor, thus allowing richer mixtures to pass to the engine for the first few strokes.

Ignition is to be accomplished on the new baby six either through the use of the Delco ignition system or Bosch high-tension magneto. One set of spark plugs is used.

The clutch, which is located in the flywheel and completely housed, consists of 30 steel plates running in oil. Four strong springs hold the plates in engagement. The gear set is of the four-speed type with reverse. Gear changes are selective, and direct drive is on the third speed. The gears are of nickel steel. Gear shifting is accomplished through the use of a center lever, which is operated by the right hand, the drive being on the left side.

From the gearset the power is transmitted to the rear axle through straight-line shaft construction, this being possible due to the three-point suspension feature. The propeller shaft has a diameter of 1 1-8 inches. The rear axle is of the semi-floating type, of usual design. The rear axle shafts which connect with the rear wheels are 1 1-4 inches in diameter. All driving shafts are of chrome-nickel steel. Nothing differing from conventional construction is to be found in the differential parts, they conforming with standard practice. The gear ratio from engine to wheels is 4 to 1 on direct drive.

Frame Thoroughly Reinforced

The three-point suspension principle is also carried out in the body hanging, the front springs being semi-elliptic and the full platform arrangement being used in the rear. The spring sizes are as follows:

Front	1¾ inches width;	34 inches length
Rear	2 inches width;	42 inches length

With this platform method of rear suspension, there is a single fastening to the rear of the body at the center of the back. This fastening bolts to the rear cross spring, which is shackled at its ends to the half-elliptics on the sides. Thus, with one rear support and one at either side in front, the three-point body suspension is carried out.

The frame is of pressed steel, hot rolled, and is of channel section. It passes in a straight line back until the rear axle is reached, where it has a kick-up to clear the latter. The frame is reinforced by four cross members, two of which are forward to carry the power plant, one a little over half way back to which the brake equalizers are fastened, and the fourth at the extreme rear.

Both front and rear wheels carry 34 by 4 inch tires, mounted on quick-detachable, demountable rims, one extra rim being furnished. Brake drums measure 14 inches in diameter by 2 inches in width, and they are bolted to the rear wheel spokes by six bolts each. The service brakes are internal expanding, and the emergency brakes are outside, contracting on the drums and operated by the conventional lever.

The steering gear, is of the worm-and-sector type. The thrusts are mounted on ball bearings and are adjustable. To prevent the front wheels from striking the fore and aft steering connections, stops are provided. The steering wheel has a diameter of 18 inches, the throttle and spark levers being located on top.

The body, a good idea of which is furnished by the accompanying illustration, is of the five-passenger type, and made of sheet steel. It is well upholstered and roomy, making for the comfort of the passengers. The door hinges and fastenings are concealed. The wheelbase of 124 inches has been utilized most advantageously, plenty of leg room being afforded in both seats. The most striking feature of the body design is its long lines and graceful contour. The front mud guards are detachable, the inner shields of these as well as those of the rear guards extending to the frame of the chassis.

Transcontinental Alco Still Going

LARAMIE, WYO., July 29—Heavy rains that washed away bridges and turned the trail ahead into a sea of impassable mud, were encountered by the transcontinental Alco truck crew during the past 2 days.

Now that the roads are comparatively dry the truck was able to start this morning along the road to Medicine Bow. In 30 days of running time it has passed through eleven states and has rolled up a mileage of 2,550 miles since the start from the factory of Charles W. Young & Company, its owners, of Philadelphia. As an example of the difficulties which the truck has met with, the following is a statement from E. L. Ferguson, captain of the crew.

Calendar of Coming Events

What the Months Ahead Have in Store for the Automobilist—Shows, Conventions, Race Meets, Etc.

Shows, Conventions, Etc.

Aug. 5-7..........San Francisco, Cal., Pacific Highway Convention.

Sept. 17-20........Denver, Col., Convention International Association of Fire Engineers.

Sept. 23-Oct. 3....New York City, Rubber Show, Grand Central Palace.

Dec. 7-22..........Paris, France, Paris Automobile Show, Grand Palais.

Jan. 4-11..........Cleveland, O., Annual Automobile Show.

Jan. 11-25, 1913...New York City, Thirteenth Annual Show, Madison Square Garden and Grand Central Palace, Automobile Board of Trade.

Jan. 20-25.........Philadelphia, Pa., Annual Automobile Show.

Jan. 27-Feb. 1.....Detroit, Mich., Annual Automobile Show.

Feb. 1-8...........Chicago, Ill., Annual Automobile Show.

Feb. 10-15.........Minneapolis, Minn., Annual Automobile Show.

Feb. 17-22.........Kansas City, Kan., Annual Automobile Show.

Feb. 24-March 1...St. Louis, Mo., Annual Automobile Show.

March 3-8.........Pittsburgh, Pa., Annual Automobile Show.

March 8-15........Boston, Mass., Annual Automobile Show.

March 17-22.......Buffalo, N. Y., Annual Automobile Show.

March 19-23.......Boston, Mass., Annual Truck Show.

March 24-29.......Indianapolis, Ind., Annual Automobile Show.

Race Meets, Runs, Hill Climbs, Etc.

Aug. 8..........Minneapolis, Minn., Annual Tour Minnesota State Automobile Association to Winnipeg.

Aug. 8-9..........Chicago, Ill., Banta Trophy Match, Chicago Motor Club.

Aug. 8-10.........Galveston, Tex., Beach Meet.

Aug. 10.......... Whittier, Cal., Hill Climb.

Aug. 30-31........Elgin, Ill., Road Races, Chicago Automobile Club and Elgin Automobile Road Racing Association.

Sept. 1-2..........St. Louis, Mo., Track Races, Universal Exposition Company.

Sept. 2.......... Indianapolis, Ind., Speedway Meet.

Sept. 2.......... Winnipeg, Man., Track Meet.

Sept. 3-6........ Chicago, Ill., Commercial Vehicle Reliability Run, Chicago Motor Club.

Sept. 17..........Milwaukee, Wis., Grand Prize Race.

Sept. 20..........Milwaukee, Wis., Wisconsin Challenge and Pabst Trophy Races.

Sept. 21..........Milwaukee, Wis., Vanderbilt Cup Race.

Sept. ....Washington, D. C., Reliability Run, Automobile Club of Washington.

Oct. 7-11..........Chicago, Ill., Reliability Run, Chicago Motor Club.

Oct. 12............Salem, N. H., Track Meet, Rockingham Park.

Nov. 6............Shreveport, La., Track Meet, Shreveport Automobile Club.

Foreign.

Sept. 26-Oct. 6....Bourges, France, Agricultural Motor Car Exposition.

Nov. 8-16.........London, England, Olympia Automobile Show.

Jan. 11-22.........Brussels, Belgium, Annual Belgian Automobile Show, Centenary Palace.

"The transcontinental Alco climbed 5,140 feet in a distance of 50 miles; then descended 1,800 feet to the plains. Here it was caught in the throes of a torrential rainstorm. The cloudburst turned the trail that was being followed into a sea of mud.

"Ahead of us were 70 miles of roads, transformed into veritable rivers. We were fortunate enough to cross one bridge between Fort Collins and this city before it was destroyed by the great cloudburst."

Trails of deep ruts and high contours are in store for the truck for a considerable part of the way through Wyoming.

Transcontinental Alco encounters weak bridge near Sterling, Col.

Right or Left Side Control?

IT will be years before all of the automobiles built in America will be either left or right-side control. Enthusiasts of left-side control expected to see every maker converted, in fact, stampeded, but they have refused to stampede. It is questionable if the tendency towards the left-side mounting of steering column and control levers is as strong as it was a year ago. At that time one or two of the biggest high-powered car builders were boldly courting the change; today they have decided to leave the column and levers on the right.

With medium-powered and low-powered machines the left-side control has made its greatest gains, with many the adoption of it being purely a selling argument. In contrast with this are the conditions of many old-established firms whose motor design is such as not to readily permit of mounting the steering column on the left and they are leaving their designs unchanged, rather than re-design the motor and add the complexity of another model to the manufacturing end of the business.

From the manufacturer's point of view the retaining of the right-side control may be desirable if he deems it unnecessary to make other changes in the model; but where he finds it necessary to re-design the motor he generally does this with the view of making it possible to mount the steering pillar on the left side if desired.

There are many engineering advantages for the left-side control, or at least advantages that go readily with this practice. With left-side control the gearshift lever and the brake lever can both be mounted on the forward end of the gearbox or on the rear end of it in the case of unit power plant constructions. This mounting frees these members from any possibility of binding due to frame warping. Their manipulation without binding is assured. Added to this is the reduced cost of manufacture due to the directness of connection between the gearshift lever and the shifter rods of these, and also an equal if not greater directness of connection with the brake control parts. In this respect left-hand control is cheaper and better. It is argued by right-hand devotees that the gearshift and brake levers can be placed in the center of the car when the steering pillar is mounted on the right side. This is true but it is also true that such combining of the parts calls for the operation of the levers by the left hand, which is not desired by many, although it has the good quality of leaving the steering wheel in the right hand, which should be important.

When the question of mounting the steering pillar on the right or left side is considered aside from its mechanical features and viewed solely from the point of advantage and disadvantage to the driver, there are points for and against each end of the argument. One of the strongest arguments in favor of the steering pillar on the left is that it permits of the front-seat passengers entering direct from the curb instead of having to walk into the street and around to the left side. This is a very important consideration, particularly in narrow city streets, where it is often necessary to wait for a fraction of a minute or more before passing vehicles will permit of entering the car from the left side. When attempting this entry on a dirty street it is often damaging to clothes because of mud splashed by other vehicles.

From the driver's viewpoint when the car is in motion the arguments are divided: locality becomes a factor, the road width becomes a factor, the horsepower of the car becomes a factor, and the design of body must also be considered. In certain localities the rules of the road are not observed as well as in others, and it frequently makes it specially dangerous for an overtaking vehicle when actually passing a slower-moving machine. With the driver on the right, he has a better opportunity of seeing just how close he can drive to the ditch, the right-side steering pillar being meritorius in this respect, and at the same time it must be remembered that as the driver has demonstrated it is not necessary to sit on the left side in order to pass a car moving in the opposite direction at the left, so it is not necessary to be sitting on the right side in order to safely overtake a vehicle on the left side.

But during a day's driving one meets many more vehicles traveling in the opposite direction than are overtaken, that is, moving in the same direction. Consequently the right-side control has the advantage in that it allows the driver to watch the ditch at his right when meeting vehicles perhaps over one hundred times a day as compared with having to watch the left ditch not more than a dozen times when overtaking vehicles. In this argument the right-side control has the advantage.

The left-side control has a distinct advantage in city driving with open cars or with any type of car in which the driver can readily look to the rear before turning across the street to the left at a street intersection or making a complete turn in the street. With a touring car with top up and side curtains in place the driver will actually have a clearer view of the street back of him when he sits on the right because his angle of vision through the back window of the top is wider when on the right side than when on the left. A test case will readily convince any driver of this situation. One factor acts against this argument, namely the carrying of a mirror on the left side of the windshield which makes it a comparatively simple matter for the driver to gauge the condition of traffic to his left and in rear of him.

There will never be any serious difficulties if makers continue to build automobiles with steering pillars on the right side and also on the left side. Machines following both designs have been in use for many years and no serious difficulties have exhibited themselves. Each has its arguments pro and con, its advantages and disadvantages, and its merits and demerits. The driver is the potent factor and with him alert, the driving advantages can be neglected in the argument and the question rested with the advantages to the occupants of the car, which is clearly in favor of the left-side pillar.

Elgin Prospects Are Booming

Fourteen Entries Have Already Been Received, Including Many Famous Drivers and Cars —Fields Sufficient in Each Event

CHICAGO, July 29—The Chicago Automobile Club now has fourteen entries for its road races at Elgin August 30-31. Besides Marhoefer in the Falcar in the Aurora cup and Bruce-Brown in the free-for-all, who were announced last week, the list includes four Mercers, four Stutzes, two Schachts and one each of the Benz, Ohio, and Falcar and Bruce-Brown's mount, which has not as yet been named.

In addition to this an effort is being made to bring over Georges Boillot, winner of the French grand prix, and his Peugeot. E. C. Patterson, a member of the Chicago Automobile Club, has cabled an offer to the Peugeot makers which it is thought they will accept, the Chicagoan agreeing to finance the expedition and not only start the car at Elgin but also put it in the Vanderbilt and grand prix at Milwaukee. Entries also are expected from Ralph Mulford, Ralph de Palma, Joe Horan, Louis Disbrow and several others. As it stood Monday, the entry list read as follows:

Aurora Cup, 231-300 class

Car	Driver	Car	Driver
Falcar	F. Marhoefer	Mercer	H. Hughes
Mercer	Not named	Ohio	John Raimey

Illinois Cup, 301-450 class

Car	Driver	Car	Driver
Stutz	G. Anderson	Schacht	B. Endicott
Stutz	Merz or Zengel		

Elgin National, under 600 inches

Car	Driver	Car	Driver
Stutz	G. Anderson	Mercer	H. Hughes
Stutz	Merz or Zengel	Schacht	B. Endicott

Free-for-all

Car	Driver	Car	Driver
Not named	D. Bruce-Brown	Mercer	H. Hughes
Benz	Erwin Bergdoll		

A conference between the Chicago Motor Club officials and the Elgin National Watch Company, donor of the Elgin National trophy, has resulted in the temporary transfer of the cup to the Chicago Automobile Club, which is given the racing rights to the trophy for this year. The deed of gift will be changed to permit of non-stock cars competing.

ROCHESTER, N. Y., July 29—Bob Burman was awarded the Remy brassard and trophy Saturday afternoon at Crittenden Park when the Blitzen Benz car made a mile in 1:29, crossing the tape several yards ahead of Elmer McDonald, in a 110-horsepower Benz machine, followed by H. Kyle in a White car. Burman was victor in every event in which he entered, having withdrawn in the seventh and final event in favor of Billy Knipper of Rochester. In the third event, Burman made one mile in 1:08, in his Blitzen Benz, almost equalling his own record of 1:07 made last year at Montreal, Que.

The Cutting was victorious in the fourth event when Burman made 3 miles in 4:09, beating Kyle, in his White by 2 seconds. Billy Knipper in McDonald's Benz car, in the final event, raced 2 miles in 3:10, nosing out Kyle in his White. Schaubert in a Cutting and Sutton, driving a Schacht car, followed.

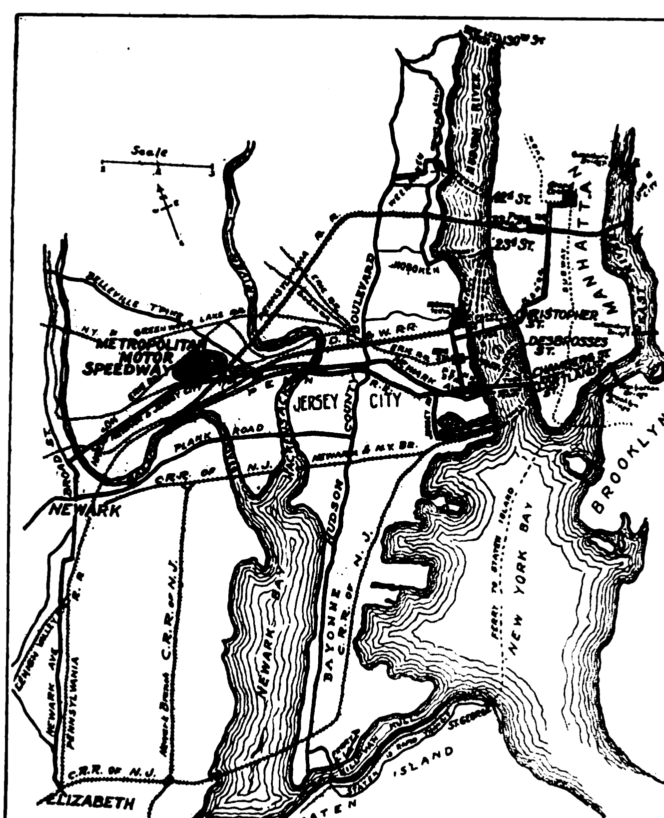
Metropolitan Motor Speedway

Location of 2-Mile Circuit Is Ideal—Accommodations to Be Provided for 200,000 Spectators —Track Will Be 60 Feet Wide

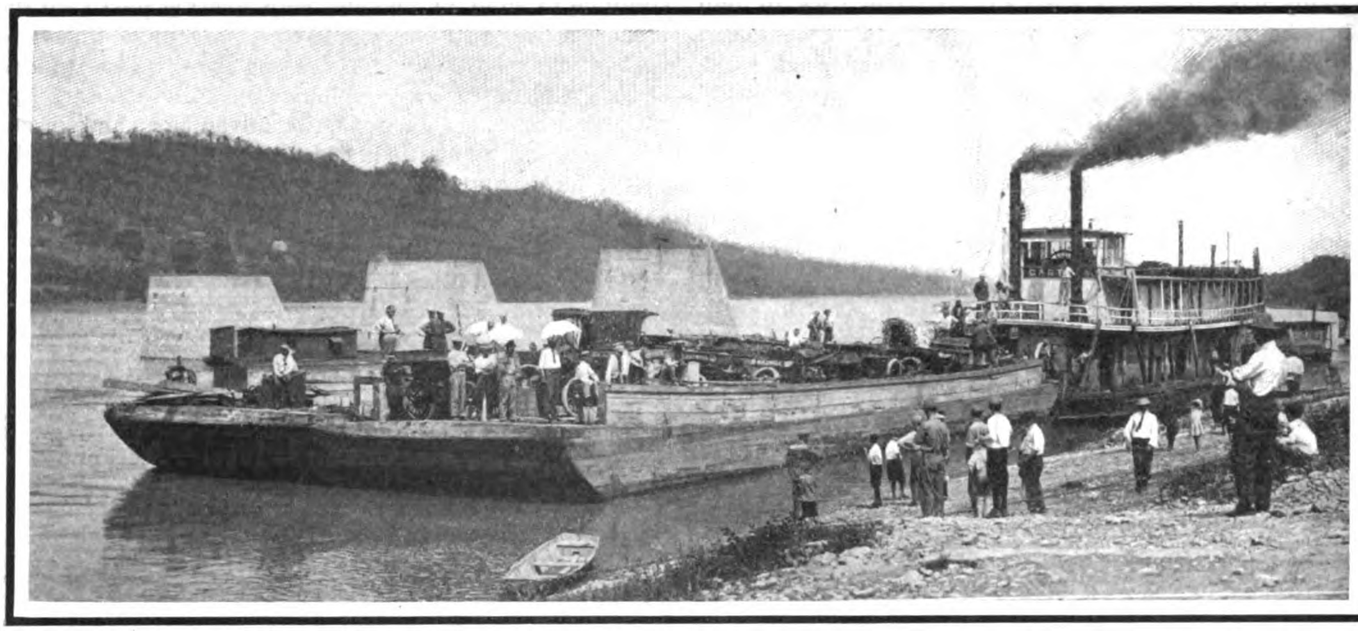
PROSPECTUSES of the Metropolitan Motor Speedway Association have been issued describing the possibilities contained in the big project to convert a section of the Meadows into a great race-track and amusement park.

Jefferson De Mont Thompson is president of the $1,500,000 corporation that has been formed to carry out the plan. A. R. Pardington is vice-president and general manager; Theodore F. Keer, treasurer, and W. H. Osborne, secretary.

The ground work of the speedway is a tract of 300 acres on the lowlands, midway between Jersey City and Newark. It is reached by four lines of transportation. It is the announced intention of the company to construct a 2-mile speedway, 60 feet wide except on the turns, where it will be 75 feet wide and scientifically banked with saucer curves. The stands will accommodate 200,000 and there will be parking spaces for automobiles sufficient to take care of 10,000. It takes 12 minutes to reach the track from downtown New York.



Map showing location of the proposed Metropolitan Motor Speedway



Four-States tourists warping into Maysville landing, where 4 hours were consumed in unloading cars

Four-States Tour Ends

All of the Twenty-Eight Pleasure and Commercial Cars Finished Intact—Business Results Good

INDIANAPOLIS, IND., July 29—Success beyond the dreams of promoters or entrants marked the finish of the second annual Indiana Four-States Tour. Tired and weary, but happy in the knowledge that they had performed their mission and worked for the good of the entire automobile industry, in other states as well as Indiana, the Hoosier tourists returned to their respective factories on July 26.

The original mileage as clocked by the pathfinders was 1,224.8, but road conditions and several detours to get around bridges coupled with two detours to take in cities not on the route, placed the final mileage at 1,423.0 miles.

The first week saw all the sales force representatives of the several companies eager to land a dealer and make the initial sales. However, the second week they were still working hard; one company having reported closing an agency in the last night control, Columbus, Ind.

The agents in the second week seemed to be the livest set of dealers of the tour, and the prospects for business in Ohio for all lines, Indiana-made and otherwise, looks to be far better than for some years.

While some of the companies did not make as pretentious efforts to obtain business as others, every one of the companies represented expressed themselves as gratified with the results. Many of these now have road men covering the territory on both sides of the route calling on the prospective business gleaned during the tour by the company representative.

An experiment tried this year was the shortening of the runs each day that the men might not grow tired so quickly. Several times the tour did not leave the night control until noon the next day and often after an early start the next night control was reached before noon. This met with the approval of some and the disapproval of others, as some hold the shortening of the time and the lengthening of the daily runs would be more conducive to success.

Road conditions were fair. In fact unless the tour was laid in the East, it is hardly probable that as uniformly good roads could be found anywhere in the country west of the Alleghanies. Many of the roads in northern Ohio were dirt. Central Ohio with the old National pike provided rather rough going for the autos. Southern Ohio and the strips in West Virginia were good. The Kentucky roads of blue limestone were excellent.

As a tribute to H. O. Smith, president of the Premier company, the tourists left the beaten trail on the way out of Lexington after visiting the home of Henry Clay, and wended their way to Versailles.

On arriving at Columbus, the tourists were greeted by Frank E. Smith, of the Maxwell plant at Newcastle, the president of the Indiana Automobile Manufacturers' Association.

Great Reception on Reaching Home

The home coming was auspicious. All the commercial bodies in Hoosier capital bid the gasoline missionaries welcome. That night they joined hands with the automobile interests and spread a banquet for the returning tourists at the German House.

During the banquet, a silver loving cup was presented to Mr. Menasco, Mr. Leeman making the speech of presentation.

Mr. Smith spoke of the injury to the trade by getting out annual models. He suggested that new models should be brought out in series, and said that annual models injure the trade with two classes of buyers—the man of moderate means, who is slow about investing, and the man of wealth who does not care to tie up his money in a product that may depreciate 25 per cent. in a season.

Mr. Handley's talk was along the line of the financial side of the industry. He said until recently it had been hard to get money to finance the industry because the financial interests had not been awake to the magnitude and soundness of the business.

Out of the twenty-four pleasure cars to start everyone finished and all in good repair. The cars had been washed frequently and as most of them were finished cars they did not show the wear that would seem unavoidable in a trip of this length. No serious accidents marked the trip.

Four heavy duty cars made the trip, the Nyberg 3-ton and the Service 2-ton trucks being the heaviest. Both of these finished in Indianapolis with the pleasure cars. The famous Premier prairie schooner was converted into an ambulance and also carried baggage. The wonder of the whole trip was the Whitesides 2-ton truck. This car built in Newcastle and accompanied by Col. V. F. Whitesides, its designer, was always the last car to leave any control. The truck carried a piano and six men and was able to make a speed of from 25 to 33 miles an hour on the road and maintain it every day.

Belgian Race Was a Fiasco

Complex Rules Prove Unsatisfactory—Jockeying and Resulting Squabbles Punctuate the 2-Day Battle

ANSEREMME, BELGIUM, July 21 (*Special*)—The following details supplement the report in last week's AUTOMOBILE on the 2-day Grand Prix road race of Belgium for 1912, in which the Silent-Knight Minerva and Hermes teams tied for first place. The race was run under experimental rules, which were found unsatisfactory. Instead of the usual practice of declaring the fastest car the winner, teams of three were admitted and a minimum average per pound, according to cylinder area, was imposed. The team most nearly adhering to this average was to be declared the winner. It admitted cars varying in cylinder area from 2 to 4 1-2 liters, the average speed for a 3-liter car, for instance, being fixed at 40 miles an hour. This average had to be maintained on individual rounds; loss of time on one round could not be made up by speeding on another one. The manufacturers themselves had decided on the averages.

The Peugeot company entered a set of 3-liter cars prepared for the French grand prix, and Boillot, who acted as race manager for his drivers Goux, Zuccarelli and Thomas, got a verbal agreement from the committee that in case of dead heat the cars most closely adhering to the average would be given the advantage. It was an easy matter for these lightweight racing Peugeots to cover the 30-mile course at a speed of 40 miles an hour. Boillot, taking advantage of the defect in the rules, stationed himself 300 yards from the timers' box and as his cars came round stopped them and gave them the start so that they could run over the line within a few seconds of their official time for finishing at the average speed imposed. So well was it done that the differences between the fastest and the slowest of the twelve rounds was not more than 5 seconds for any one of the three cars. But four other teams, Mercedes, Opel, Minerva and Hermes, finished without the loss of points, though not with the same absolute and artificial regularity, and when Boillot claimed the advantage he was informed that all five sets of cars were considered equal.

There was a wordy battle, in which the jury remained firm in its decision that the second day's run of 360 miles should be started with the five teams classed equally. Dissatisfied at the decision, the Lion-Peugeot men were given the order to go all out on the second day, while the Minerva managers, who had objected to the artificial timing of the Peugeot men, openly adopted their tactics. The crowd got on the course during the initial round, and to avoid a disaster Goux had to brake furiously. The effort caused injury to his universal joint, necessitating a roadside repair which made it impossible for his Lion-Peugeot to finish the initial circuit in the limit imposed. He had no further trouble, and ran throughout at an average of 50, but his point penalization was ineffacable. Later Zuccarelli had trouble with his overhead timing gear which caused his elimination. This left Thomas as the only clean score man of the team.

Minerva, who ran with the Knight motor of 3.1 by 4.8 inches bore and stroke, finished the 720 miles at the imposed average of 38 miles an hour, thus securing the maximum number of points for its team of three. Hermes, a Belgian firm with a four-cylinder model of 2.8 by 4.7 inches bore and stroke, also maintained its average—35 miles an hour—throughout the distance, being the prizes between these two. . The following are the official particulars of the cars, and speeds imposed:

Car	Bore and stroke	Cyl. area	Speed imposed
Minerva (Knight motor)	3.1 x 4.8	3 liters	40 m.p.h.
Hermes	2.8 x 4.7	2 "	35 "
Mercedes (Knight motor)	3.9 x 5.5	4.4 "	44.4 "
Opel	2.7 x 5.1	2.1 "	35.3 "
Lion-Peugeot	3 x 6.1	3 "	40 "
Schneider	3.2 x 5.5	3 "	40 "
Germain (valveless)	3.6 x 5.9	4 "	43 "
Sava	3.2 x 5.5	3 "	40 "
F. A. B	2.9 x 4.7	2.2 "	35.5 "
Miesse	3.5 x 5.5	3.6 "	42 "
Ford	3.7 x 4	2.9 "	39.9 "

Just before the start of this race Michelin made the official announcement that he would take no further part in automobile racing. No reason is given for this withdrawal.

Twenty Clean in Farm and Ranch

DALLAS, TEX., July 30—The tour for the farmers and ranchmen of Texas under the auspices of the Farm and Ranch Publishing Company, of Dallas, ended Saturday. Twenty of the twenty-six cars which left Dallas on the Monday previous returned on Saturday morning, and fourteen of the number had perfect scores. On arrival in Dallas the contestants were given an elaborate banquet where the prizes of $1,000 were distributed.

The tour extended over more than 700 miles of Texas' richest agricultural section and a number of the important cities were touched. The names of the contestants who finished with perfect scores were as follows: First division, touring car class: W. R. Bishop, Franklin; J. M. Howe, E-M-F; W. R. Mickle, Chalmers; R. B. Dunn, Mitchell; B. W. Bean, E-M-F; B. W. Rutherford, Maxwell, O. L. Sims, Overland; J. Mantel, Hudson; H. V. Kendrick, Buick; S. J. Hall, Hupmobile; W. H. Camp, Reo; W. R. Newton, Ford; R. J. Roach, Ford. Second division, runabout class: L. B. Blair, Maxwell.

Promoters Quietly Abandon Course First Announced and Sign Up All Property Owners Along New Route

MILWAUKEE, WIS., July 29—The four international road racing classics to be run at Milwaukee on September 17, 20 and 21, will use a course 8.2 miles long lying entirely within the township of Wauwatosa, Milwaukee county, instead of the much-touted Greenfield course, in the township of Greenfield, Milwaukee county.

After 2 months of quiet preparation, the Milwaukee Automobile Dealers' Association, promoter of the great speed carnival, announced today that the Greenfield course was secretly abandoned on June 1, on which date the town board of Wauwatosa presented an offer to the association of an 8.2-mile course in its township, under the condition that nothing in relation to the new course be made public until the last and final details had been completed. The offer of the Wauwatosa board included the completed course, together with all property rights, for a period of 3 years, taking from the shoulders of the M. A. D. A. the entire expense of building the roads into shape for high speed, which amounts to approximately $2,000 per mile, or $16,500.

The course will consist entirely of concrete road, with a 30-foot roadway, built under the direction of the state highway commission, with state aid. The turns, all of which will be rebuilt, will be of concrete, but the M. A. D. A. will be obliged to stand the expense, as the turns will be through private propery excepting in one instance, and the plan under which the town board is building the road will not permit of the construction of special turns for high-speed work at public expense.

The reason that the new course has been kept so absolutely secret for nearly 2 months is that the M. A. D. A. wished to avoid the many harassing difficulties that confronted it almost as soon as announcement of the selection of the Greenfield course was made early in the spring. After signing up all but one or two of the property-owners and residing tenants, the M. A. D. A. believed everything secure when it was discovered that Chicago and Eastern concessionaires were bidding for rights along the roads and when the situation was investigated, it was found that almost every foot of the course would be covered with peanut stands and soda water bars.

Just at this time Chairman Joseph M. Guentner, of the town board of Wauwatosa, approached the association with an offer to build a course and insure titles to every foot of ground bordering on the roads comprising the route, providing the association would keep it a secret until all details were completed. It was a most fortunate turn of affairs, and the offer was eagerly accepted. Two days later the town board had received the signatures of 98 of the 101 property-owners along the course. Within a week every one had been signed up. On June 29 the contract for building 8.2 miles of concrete road was awarded to Michael Schmidt, a reliable contractor of Wauwatosa city, and today concrete is already being poured at 10 points on the roads.

Description of the Circuit

The Wauwatosa course is a parallelogram, comprising the old Fond du Lac highway, from the northwestern corner of the city limits of the city of Milwaukee to the point of intersection with the Town Line road dividing the townships of Wauwatosa and Granville. It runs in a northwesterly direction. At the intersection the course runs due west along the Town Line road to Sommerville, where it intersects with the new Fond du Lac road, which it follows in a southeasterly direction almost parallel with the old Fond du Lac road. At the intersection of Burleigh road, the continuation of Burleigh street in the city of Milwaukee, the course strikes due east to the old Fond du Lac road. The two Fond du Lac road straightaways are each approximately 3 miles long; the Town Line road measures approximately .9 mile, and the Burleigh road 1.3 miles.

The Wauwatosa course is far superior to the abandoned

Greenfield course in every particular. It is almost flat throughout its entire length. The old Fond du Lac road is a straightaway as flat as a prairie road and it is here where the highest speeds will be attained. The new Fond du Lac road is not so regular, but probably more so than the most regular part of the old Greenfield course. The connecting roads at the north and south ends of the course are somewhat rolling, but the grades do not rise above 7 per cent. at any point.

There are two bad turns and two exceptionally good ones. The turn at Wanderer's Rest cemetery in the southwestern corner of the course, will have to be only slightly changed. It is a four-point cross-road, with rounded turns into each of the four connecting roads. The sweep from the new Fond du Lac road into the Burleigh road is one of approximately 145 degrees.

Advantages of the New Course

The Sherman Park turn, at the southeastern end, and the Sommerville turn at the northwestern corner, are very sharp and the town board is cutting a way through private property to make the round safe. The inside of the two turns barely measures 45 degrees. The Mud Creek turn at the northeast corner of the course measures about 120 degrees.

The location is ideal from a standpoint of accommodating the crowds. Two principal street car lines of the city of Milwaukee terminate at the two south corners of the course. They are fed by more than a score of trunk lines in the city limits. The main line of the Chicago, Milwaukee & St. Paul runs by the course, a half mile from the east leg.

The north city limits of the city of Wauwatosa are but 3-4 mile south of the lower end of the course, while the village of North Milwaukee lies about 3-4 mile northeast. The course touches the city limits of Milwaukee proper at the southeastern corner.

Records at Grand Rapids

Disbrow in Simplex Creates New Track Records—Dawson Suspended, Not Allowed to Start

GRAND RAPIDS, MICH., July 29—Before a monster crowd here last Saturday, Louis Disbrow, in his Simplex, broke two local records, established by De Palma, at the Comstock park mile circular track. Disbrow made 5 miles in 4:34.10 and 10 miles in 9:08.98. The previous records were: For 5 miles, 4:50, and for 10 miles, 9:22.

Dawson and his National were to have featured the program, but at noon, shortly before the races began, notice was received from the A. A. A. officials in New York that Dawson had been suspended from organized automobile racing because he participated in an unsanctioned meet at Memphis, Tenn., a short time ago.

Dawson's explanation of the Memphis affair is that he supposed the meet had the sanction of the A. A. A. Summary:

Time trials, one mile—Louis Disbrow (Case), 58.41; Heine Ulbrecht (Case), 1:01.32; Bill Endicott (Schacht), 59.54; Joe Nikrent (Case), 1:02.04.

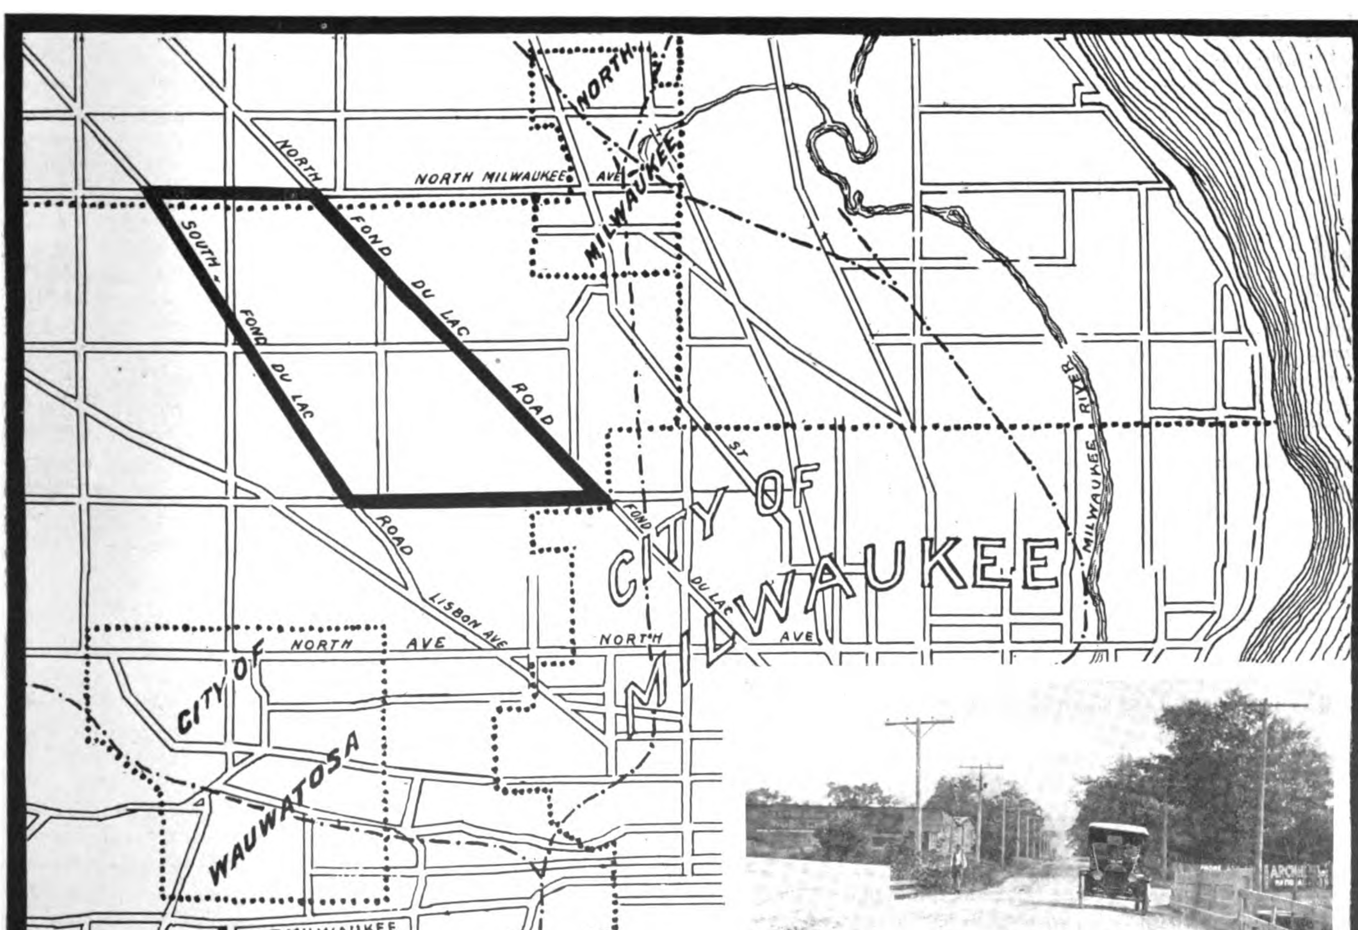
Five Mile—Joe Nikrent (Case), first; Bill Endicott (Schacht), second; Heine Ulbrecht (Case), third; time, 6:05.69.

Australian Pursuit Race—Disbrow (Simplex), won at end of fourth mile in ten mile race.

Exhibition Mile—Disbrow (Case), 57.97.

Five Mile Handicap—Disbrow (Simplex), first, 5:34.89.

One Mile Exhibition—Disbrow (Simplex), 53.59.



Wauwatosa course, 8.2 miles in length, which will be used by the racing cars contesting in the classics in September

Amenities of Racing on Half-Mile Tracks

Fences Proved Bothersome on the Wilkes-Barre Oval, Where Several Accidents Were Averted

WILKES-BARRE, PA., July 29—Saturday's race meeting on the half-mile track at the Driving Park was interesting to the good crowd that assembled. Dust was prevalent once more, just as it had been at the former meetings, despite the efforts of the promoters to lay it. Whalen's National was hard to beat in the races in which it was entered; in fact, it cleaned the boards on several occasions. The Mercer pair, Buick and E-M-F, made excellent showings. The summary follows:

Position	Car	Driver	Time
	Three miles, non-stock		
1	Buick	Williams	4:21½
2	E-M-F	Billy Burke	
3	Ford	Douglas	
	Five miles, non-stock		
1	Buick	Ringler	8:09½
2	Mercer	John De Palma	
	Five miles, non-stock		
1	National	Whalen	7:08
2	Mercer	John De Palma	ffl
3	Mercer	Ringler	
	Five miles, non-stock		
1	National	Whalen	7:05
2	Mercer	Ringler	
3	Mercer	John De Palma	
	Ten miles, non-stock		
1	National	Whalen	14:05 4/5
2	Mercer	Ringler	
3	Mercer	De Palma	
	Five-mile handicap		
1	E-M-F	Billy Burke	
2	Mercer	De Palma	

Hairpin Turns, Four to the Mile, Proved a Bar to the Creation of Records at Scranton

SCRANTON, PA., July 29—Neil Whalen in a National proved to be the star of the race meeting held on the half-mile track of the Minooka Driving Park Wednesday. The combination won the 3 and two 5-mile events for non-stock cars but was beaten in the handicap race by a Buick driven by Williams.

A fair attendance, estimated at 1,400, witnessed the trials. Williams also won two other events. The summary follows:

Position	Car	Driver	Time
	Three miles, non-stock		
1	Buick	Williams	4:32 2/5
2	Ford	Douglas	
	Exhibition, one mile		
1	Fiat	William Freitag	1:14
2	National	Neil Whalen	1:20
	Five miles, non-stock		
1	Buick	Williams	6:30
2	Mercer	Ringler	
	Three miles, non-stock		
1	National	Whalen	4:06
2	Marmon	Freitag	
	Five miles, non-stock		
1	National	Whalen	6:52
2	Buick	Williams	
3	Mercer	De Palma	
	Five miles, non-stock		
1	National	Whalen	6:32
2	Buick	Williams	
	Free-for-all, handicap, five miles		
1	Buick	Williams	6:06
2	National	Whalen	
3	Fiat	Freitag

Fleet of Baker electric trucks which formed part of Cleveland's Fourth of July parade

BAKER Busy Selling Trucks—The ten Baker electric trucks shown on this page were part of a line of fifteen Bakers participating in Cleveland's Sane Fourth of July parade. Twelve Baker 2-ton trucks have been shipped to Washington, D. C., where they will be put in service by the American Express Company. The Baker Company at the present time holds orders equally as large as the Washington installation for seventeen other cities in the United States. These orders are additional to the earlier installations of Baker electric trucks which amounted to about a hundred cars in New York, Boston and other cities.

Dingley Takes National Car—Bert Dingley last week took his place as Los Angeles manager of the National Motor Car Company.

Nichols Joins Boston Chalmers—Fred W. Nichols, well known in Boston automobile circles, has joined the Chalmers Motor Company as assistant to Percy Owen, sales manager.

Brown Northwestern Studebaker Manager—A. H. Brown, manager of the Spokane branch of the Studebaker Corporation, of this city has been appointed northwestern sales manager for the company.

Dansville Board Sociability Run—The second annual sociability run of the Dansville, N. Y., Board of Trade, was made last Friday, Dansville to Canandaigua and return. About fifty machines participated.

Diamond Rubber Buffalo Branch—The Diamond Rubber Company, Buffalo, N. Y., has opened a mechanical goods branch at 721 Main street, that city. A. A. Lyon has been appointed manager of the branch.

Hanes Leaves Tiffin Taxicabs—The announcement is made that after July 13 E. C. Hanes severed his connection with the Tiffin Auto & Taxi Company of Tiffin, O. C. H. Lines and E. J. Rosenberger have entire control of the taxicab-operating concern.

Twin City Timken Agency—The Pence Automobile Company, Minneapolis and St. Paul, has been appointed agent in Minnesota, the Dakotas and Montana for the Timken tapered roller bearings.

Hartman Goes to Detroit—Charles W. Hartman, manager for the Studebaker Company in Dallas, Tex., and other representatives of the company in Texas have gone to Detroit, Mich. Plans are said to be under way for carrying on a larger business in Texas.

Menhall Enters Traveling Field—James W. Menhall, state agent for the Brush and Courier, and local representative of U. S. Motors products, and operating the largest garage at Beloit, Wis., will retire from business locally on August 1 to become traveling representative of the U. S. Motor Company in Wisconsin.

Sacksteder and Potter Resign—M. A. Sacksteder, formerly manager, and C. H. Potter, formerly assistant manager, for the United Motor Company in Texas, have resigned their positions and intend to open up a house for the sale of the Marion and the American cars. They are now on a tour of the North and expect to return to Dallas in the course of a few weeks to carry out the plans proposed.

Coler Overland Advertising Head—Announcement has just been made in Toledo, Ohio, of the appointment of Ernest Coler as manager of the advertising departments of the John N. Willys group of motor car factories. Mr. Coler will supervise the work of the departments of the Garford at Elyria, Ohio, the Gramm Truck Company, Lima, Ohio, and the Willys-Overland Company in this city.

Yeoman Joins Ames Company—George W. Yeoman, well known as sales and advertising manager of the Continental Motor Manufacturing Company of Detroit and Muskegon, Mich., has severed his connection with that company to ener a broader field as manager of the Ames Motor Car Company of Owensboro, Ky. Mr. Yeoman is vice-president

International Motor Company's new motor street sprinkler

Haynes Purchases California Company—The Haynes Automobile Company have purchased control of the Haynes Auto Sales Company of San Francisco, and announce the appointment of W. B. Cochran as direct factory representative.

Rose Leaves Studebaker Company—L. H. Rose, for five years manager of the Northwest branches of the Studebaker Corporation, has resigned that position to become head of the Northwestern agency of the Metzger Motor Car Company.

Sackett Takes Boston Oakland—Louis J. Sackett, one of the pioneers in the motor industry, who began his career in 1898, and was recently with the Cadillac agency in Boston, has been appointed manager of the Boston branch of the Oakland.

Satterthwaite Manager Whiting Company—J. G. Satterthwaite has been appointed manager of the Whiting Motor Company of New York, distributor of Mercer cars. His quarters are at Philadelphia, Pa., on the northwest corner of Broad and Green streets.

Mann Introduces Road Bill—Minority Leader Mann of the House of Representatives has introduced a resolution providing that all money received from the operation of the National parks be turned into the fund set aside for road improvements and bridge building.

Canadians Pay Hard for Gas—Automobile dealers at Hamilton, Ont., have raised the retail price of gasoline from 20 to 25 cents a gallan. This rate has been charged for some time by a number of oil and gasoline dealers in Ontario, but it was only last week that the Hamilton supply houses fell in line.

Reselling Cars Not Quite Simple—Secretary of State of California has issued a statement calling attention to the law whereby persons who have sold their automobiles are still subject to be taxed for them unless they have had their cars transferred to the new owners in the regular way through the office of the automobile license department.

Detroit Agencies Change Hands—Harry Postal and Richard Fair, of Detroit, Mich., have formed the Postal-Fair Motor Company, which has succeeded the Lion Motor Sales Company. The new company is a branch of the Michigan Motor Car Company of Kalamazoo, and in addition to that company's products handles the Lion and Peerless cars.

Street Regulations in Maryland—Maryland owners have been notified by the Automobile Club of Maryland that the club has received word from Justice of the Peace C. Scott Rickards, of Delaware County, Pa., that a law exists in that State prohibiting drivers of motor vehicles from passing trolley cars while the cars are stopped to let off or take on passengers.

Speed Case in Maryland Court—Counsel for the Automobile Club of Maryland has been authorized to appeal to the Circuit Court of Baltimore County against the decision of Justice Charles J. Hull convicting William J. O'Brien of speeding along Wilkens avenue, Baltimore, Md. The case will involve the right of the local authorities to prescribe a speed limit of 12 miles along Wilkens avenue.

Trego, Thomas Engineer, Resigns—Frank H. Trego, chief engineer of the E. R. Thomas Motor Car Company, Buffalo, N. Y., has resigned and his resignation will take effect on September 1. Mr. Trego has been chief engineer of this company since its recent reorganization and previous to that time was head of the maintenance department with the Hudson Motor Car Company.

Splitdorf Opens Service Department—Quarters for a New York service department of the Splitdorf Electrical Company have been secured on Broadway, near Sixty-second street. This store will also be utilized as the carbureter department of the company. The work of transferring a portion of the manufacturing operations of the company to the plant of the Eagle Company is progressing, but the present Bronx establishment will not be abandoned.

International Motor Company's Sprinkler.—The International Motor Company has begun the development of municipal automobiles, which offers some very practical and exclusive points of design. This company has recently sold to the City of St. Louis, a motor street sprinkler of unique design. This water wagon is built on a 6½-ton Standard Saurer chassis. The Gould pump equipment has a capacity of 400 gallons per minute against a pressure of 30 pounds of the pump circuit, and ten to twelve pounds at the nozzle. The pump is geared at 400 R.P.M. at a truck speed of 6 miles per hour which gives a water distribution of one gallon per 45 square feet. Control of the sprinkler is effected by two levers. The nozzles are easily adjusted to the full limit of useful nozzle pressure, in addition to an adjustment by a single ring nut which permits the throw of the water from the nozzles to be regulated for varying widths of streets, making the equipment a very practical one.

Automobile Incorporations

AUTOMOBILES AND PARTS

ALEXANDRIA, VA.—Check Spring Motor Company; capital, $100,000; to manufacture automobile engines and parts. Incorporators: C. E. Hooper, C. L. Lamber, A. S. Check.

CANTON, O.—Central Motor Car Company; capital, $25,000; to engage in the automobile business. Incorporators: R. F. Wilson, D. L. Tschantz, D. B. Wilson, Maggie Tschantz, Emma Wilson, Anna Herr.

CINCINNATI, O.—Cincinnati Motor Car Company; capital, $10,000; to manufacture automobiles for pleasure and commercial purposes. Incorporators: C. D. Wilson, H. C. Heisey, M. C. W. Shepler, J. C. Miller, R. M. Comer.

CINCINNATI, O.—Welbon Motor Car Company; capital, $25,000; to engage in the manufacture of automobiles. Incorporators: W. E. Welbon, H. S. Leymann, C. D. Wilson, C. W. Shepler, H. A. Welbon.

CLEVELAND, O.—Arter Auto Carriage Company; capital, $20,000; to manufacture, sell and repair automobiles and other vehicles, also to deal in parts and accessories. Incorporators: James G. Arter, B. Hexter, James B. Ruhl, C. A. Chapman, C. M. Lemmon.

MARION, IND.—Rutenber Motor Company; capital, $1,350,000; to manufacture automobile motors and parts. Incorporators: George W. Bowen and others.

MEMPHIS, TENN.—Southwestern Motor Car Distributing Company; capital, $50,000; to engage in the automobile business. Incorporators: J. W. Bondurant, N. S. Bruce, T. B. Crenshaw and others.

NEW YORK CITY.—L-M-S Motor Company; capital, $10,000; to manufacture automobile motors and other parts. Incorporators: Joseph J. Baker, Emil Akder, Herbert Cohen.

NEW YORK CITY.—Standard Automobile Company; capital, $10,000; to engage in the automobile business. Incorporators: Earl H. Fetchman, Henry B. Chapin, Alfred Freeman, Jule L. Janever.

NEW YORK CITY.—William Strathmann, Incorporated; capital, $5,000; to deal in motors, automobiles, etc. Incorporators: William Strathmann, Herman C. Birkemeyer, John H. Semken.

GARAGES AND ACCESSORIES

AKRON, O.—Akron Airless Tire Company; capital, $50,000; to manufacture and sell tires and other rubber products. Incorporators: William S. Brooks, Joseph J. Surbey, Ira H. Thompson, Frank H. Beyea, H. Lane Cole.

AKRON, O.—Majestic Rubber Company; capital, $3,000; to manufacture rubber goods of all kinds. Incorporators: E. Christian, O. W. Baum, J. A. Myers, A. L. Neiswanger, J. H. Ault.

BROOKLYN, N. Y.—E. Reineking Automobile Supply Company; capital, $5.000; to engage in the accessories and supply business. Incorporators: Emil Reineking, John Lucht, Bernard F. Nienstedt.

St. Louis Rubber Branch Moves—The United States Rubber Company, St. Louis branch, has moved into its new quarters at Compton avenue and Locust street.

Cadillac Branch for Sacramento—Don Lee, California distributor of the Cadillac line, has recently opened a branch in Sacramento, Cal. E. G. Anderson will be resident manager.

Franklin Announces Little Six—The Franklin Automobile Company, Syracuse, N. Y., announces that it will add to its line a two-passenger runabout built on the Little Six chassis.

Prest-O-Lite Opens St. Louis Branch—The Prest-O-Lite Company, of Indianapolis, has opened a service station at Channing and Locust streets, St. Louis, Mo., in connection with its branch.

Hall Oldsmobile Sales Manager—The appointment of J. V. Hall, manager of the Oldsmobile Company of Illinois, as general sales manager of the Olds Motor Works of Lansing, Mich., has been announced.

Smith Made Olds Ad Manager—L. Clyde Smith, assistant to the director of advertising of General Motors Company, Detroit, has been appointed advertising manager of the Olds Motor Works, Lansing, Mich.

Boston Mayor Buys Knox—Mayor John F. Fitzgerald, of Boston, has just bought a big six-cylinder Knox car in which to travel about on his duties as mayor, and as he is a candidate for United States Senator, the car will be seen flying about the state this fall on his stumping tours.

Chicago Buys Michigan Bonds—County Clerk Glorum, of Grand Haven, Mich., has received $100,000 from John Nuveen & Company, of Chicago, in payment for part of the issue of $600,000 good-roads bonds recently voted by the citizens of Ottawa county. Work on the roads will be begun at once.

White and Maroon N. J. Colors—The color scheme of the 1913 tags for New Jersey will be a white background with maroon letters and figures. This combination, the commissioner thinks, will be such as to make identification of the tags easy. The contract for the tags will be given out soon.

Automobile Incorporations

CINCINNATI, O.—Swing Wheel Automobile Company; capital, $50,000; to manufacture wheels for automobiles. Incorporators: A. J. Swing, Richard E. Warner, Rupert H. Langdale, C. A. Beckett, Richard A. Beckett.

DAYTON, O.—Automatic Lamp Control Company; capital, $15,000; to manufacture automobile control mechanisms for automobile lamps. Incorporators: Henry Ehlen, Ernest A. Eastman, William B. Meeker, Joseph Friedman, Mary E. Eastman.

DAYTON, O.—Stocker Rubber Company; capital, $10,000; to deal in automobile tires and other accessories. Incorporators: A. D. Stocker, Ira J. Cooper, H. H. Brewer, F. W. Johnson, J. W. Brumbaugh.

DAYTON, O.—Walter & Moosburger Company; capital, $10,000; to operate an automobile livery business. Incorporators: L. F. Walter, William H. Moosburger, W. C. McCommaughey, J. J. Lynch, John C. Shea.

EAST PALESTINE, O.—East Palestine Rubber Company; capital, $50,000; to manufacture tires and other rubber articles. Incorporators: R. E. Jones, Ulrich Winter, C. A. Oatsdean, Joe Hick, O. L. Shumate, A. S. Mauk, Albert Hartley.

GARDNER, MASS.—Brown-Rawson Garage Company; capital, $5,000; to conduct a garage and repair shop. Incorporators: Shirley J. Rawson, Harry W. Brown, Maud L. Rawson, Claribel Brown.

NEW YORK CITY.—Autodrome Company; capital, $50,000; to conduct racing exhibitions, deal in automobiles, aerial craft, etc. Incorporators: Harry L. Curran, Claire D. Curran.

NEW YORK CITY.—Automobile Importers Alliance, Incorporated; capital, $750. Incorporators: George J. Ginsburg, Hubert L. Wymer, Bernard C. Wymer, Henry W. Showers.

PATERSON, N. J.—Paterson & New York Motor Express Company; capital, $50,000; to conduct a general express business. Incorporators: John M. Simpson, Mary Brooks, Henry Smith.

SHEBOYGAN, WIS.—Sheboygan Auto & Supply Company; capital, $15,000; to conduct a garage, repair shop, paint shop and deal in accessories and supplies. Incorporators: Charles F. Kade, Sr., Charles F. Kade, Jr., Robert H. Thieman, Caroline Thieman.

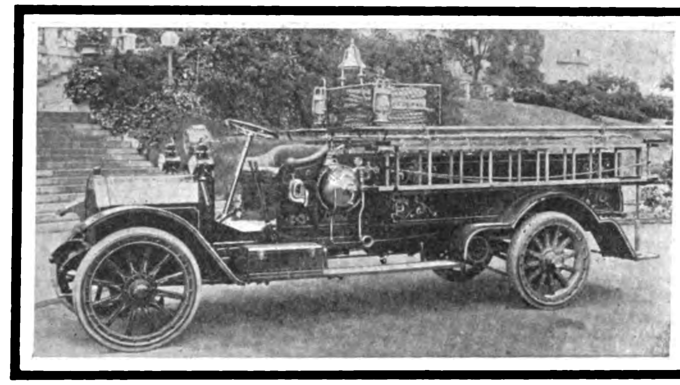
WILMINGTON, DEL.—Protective Auto-League; capital, $1,000,000; to represent the interests of automobile owners and operators. Incorporators: Isaac Fogg, George D. Hopkins, George W. Dillman.

CHANGES OF CAPITAL AND NAMES

CINCINNATI, O.—Jewel Carriage Company, changed name to Ohio Motor Car Company.

INDIANAPOLIS, IND.—Cole Motor Car Company, increased capital stock from $300,000 to $500,000.

TOLEDO, O.—Willys-Overland Automobile Company, capital stock increased from $6,000,000 to $15,000,000.



Chemical and hose truck turned out by the Federal Motor Truck Co.

Plans Track Near Fresno—A four-mile automobile race track near the town of Sanger, Cal., is being planned by W. D. Mitchell, a member of the board of supervisors. Neither time nor money will be spared to make it one of the finest speedways in the country. The location is within a few miles of Fresno, Cal.

Kalamazoo-Battle Creek Road—Prominent men of Kalamazoo and Battle Creek, Mich., are planning to build a macadamized road to connect the two cities. The road is to pass through Augusta, Galesburg and Comstock. The proposed road will be 23 miles in length and one of the finest automobile drives in America.

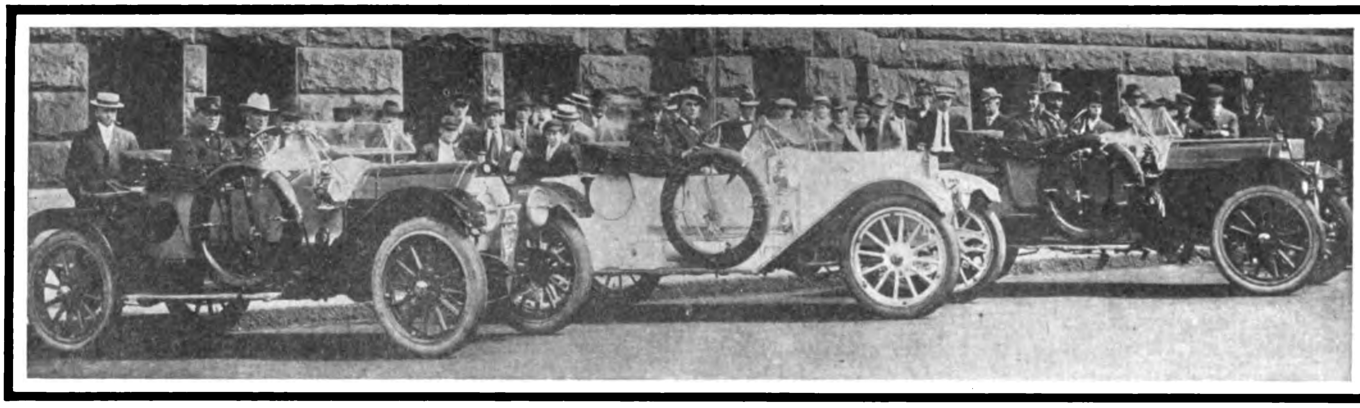
Los Angeles Business Change—The Los Angeles agency of the Stevens-Duryea automobile has passed from the Eastern Motor Car Company to the recently incorporated English Motor Car Company, of which P. A. English is president and Clarence A. English secretary and general manager. Temporary quarters have been secured at 1036 So. Grand avenue.

Louisiana Road Building Progress—One of the ante-election pledges of the present Louisiana Governor was to encourage the good roads movement. By dividing the parishes into road districts and putting a bill through the legislature providing for the application of certain portions of the levee tax fund to road building the promises have been kept. An increasing amount of interest in good roads is noted throughout the state.

Results of California Run—Edward J. Lyon won the Imperial Valley, Cal., road race on July 4th, in a 1909 40-horsepower Buick roadster, defeating a field of eleven entries, only four of which finished. A 30-horsepower roadster, driven by Clarence Conan, finished second. The course led through the towns of Brawley, Imperial, El Centro and Hopeville, covering a total distance of 206 miles and crossing 305 bridges built across irrigating canals.

Gotham Limit 15 Miles—Provided the ordinance proposed and recommended by the special committee of the New York City Board of Aldermen is adopted by the board, a speed limit of 15 miles an hour will be imposed on the motor vehicles in New York City, beginning September 1. A minimum fine of $25 and a maximum of $100, with imprisonment for 15 days or less, will be the penalty imposed for the first offense, and for the second a fine of $50 to $100 or imprisonment for 30 days.

To Change California's Laws—The need of new automobile legislation in California, which will replace the many antiquated and unjust measures pertaining to motor cars that are now on the statute books, is well recognized by the Automobile Club of Southern California. This organization has a legislative committee that has been engaged during the past year in drafting bills that will be submitted at the next legislative session and are designed to thoroughly revamp and reconstruct the motor laws of the state.



Chiefs of the Minneapolis Fire Department have been provided with Cole roadsters for quick duty

Touring Club's Work—The Touring Club of America is placing detour signs at points upon the main thoroughfares where it is necessary for tourists to avoid roads that have been closed for repairs or reconstruction.

Weissenburger Transferred—M. A. Weissenburger, who has been traveling in the New England states and the territory adjacent to New York City, has been transferred by the Regal Motor Car Company to the Pacific Coast.

Cole Cars for Fire Chiefs—The fire department of the city of Minneapolis, Minn., now owns twelve pieces of automatic fire apparatus. The latest addition to the city's fleet consists of three Cole roadsters, purchased for the work of the fire chiefs.

Tacoma's New Automobile Firm—The latest firm to join Tacoma, Wash., automobile row is the Union Motor Car Company, which will be located at 717 South C street. The new concern will handle Pope-Hartford, Peerless, Chalmers and Buick machines.

Oppose Double Automobile Taxation—About 300 Mississippi automobile owners have joined in an effort to restrain the recently adopted state automobile tax, which goes into effect Thursday. James R. McDowell, former assistant attorney general of the state, has been retained to conduct the case. The fight will be made on the ground that the payment demanded is double taxation, and also is class legislation.

Walpole Company Growing—The Walpole Rubber Company, which recently entered the tire making field at its plant at Walpole, Mass., has found the buildings there inadequate to get out as large a supply as the business warranted and so an unused factory at Foxboro, Mass., embracing 3 acres of floor-space has been secured and the work of installing tire machinery will begin at once. The company plans to turn out 1,000 tires a day in this new plant.

Experimenting with Automobile Bus—Arrangements have been made by the Pittsburgh, Pa., Council with an automobile company to place an experimental pay-as-you-enter automobile bus in Schenley Park about August 1. The vehicle will accommodate from thirty-six to forty persons. If the experiment proves a success the council may buy a number of machines for the parks instead of installing a street car line in the park.

FRANKLIN Announces Little Six—The Franklin Automobile Company, Syracuse, N. Y., announces that it will add to its line a two-passenger runabout built on the Little Six chassis.

Norwalk 1913 Roadster Ready—The first 1913 model of the Norwalk 45 roadster has been completed at the factory along the Cumberland Valley railroad near Martinsburg, W. Va. The factory will be kept busy from now on turning out cars for immediate shipment.

Fritchle Plant for Bridgeport—Bart Roeder, President of the Eastern branch of the Fritchle Electric Vehicle Company of Denver, Colo., who has been making a tour of Southern New England seeking a location for a factory to build Fritchle vehicles, has determined to locate at Bridgeport, Conn.

Dorris Ready for Operation—The brick work on the new Dorris plant at Sarah street and Laclede avenue, St. Louis, Mo., has been completed and the company will move in about September 1. The Dorris production will be increased 50 per cent. for 1913. The concern will also increase its capacity for building trucks.

Columbus Auto Brass Building—The Columbus Auto Brass Company, Columbus, O., which has been operating a plant for the manufacture of auto supplies and accessories at 175 West Maple street, is erecting a new factory at the corner of Fourth and Warren streets. It is expected to move into the new plant in about two months.

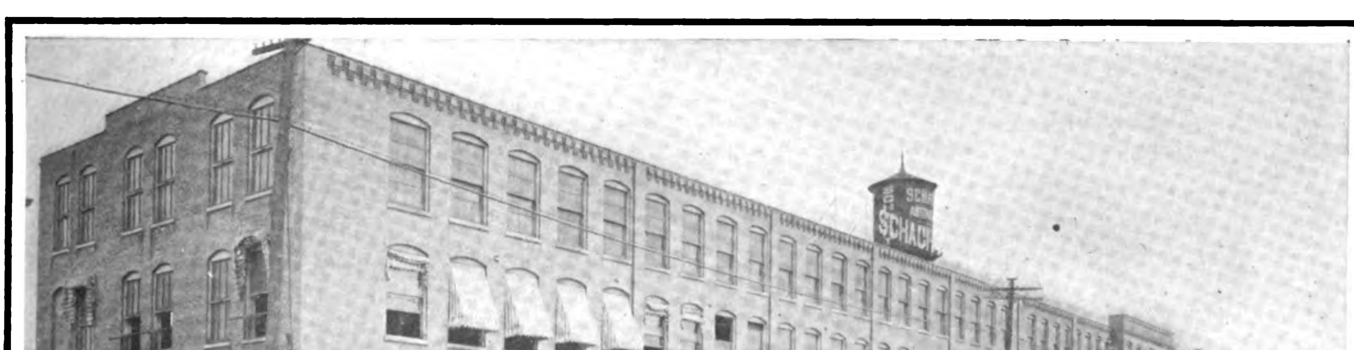
East Palestine's Tire Plant—It is now practically assured, through the efforts of the board of trade of East Palestine, O., working in conjunction with the people, that East Palestine will soon see the erection of a rubber tire manufacturing plant. The company asks a bonus of $3,500, which amount the board of trade is endeavoring to raise.

Lease Cortland Factory Building—Frederick R. Thompson and George A. Brockway, both of Homer, N. Y. have leased the plant of the Ellis Omnibus and Cab Company, Cortland, N. Y., for their factory where they will manufacture motor trucks. The plant was leased with an option for purchase if later desired.

Prest-O-Lite's New Factory—The Prest-O-Lite Company will build a $30,000 brick, stone and reinforced-concrete structure to be used in the automobile industry, in Grant boulevard, Pittsburgh, Pa. The structure will be 75 by 100 feet, one story high on the boulevard side and three stories high in Brereton avenue. There will be about 18,000 square feet of floor space.

Factory Opened at Brockville—A carriage company at Brockville, Ont., has begun the manufacture of automobiles this season. The machine it manufacures is called the Atlas. The motor, wheels, chassis and nearly all the other parts are imported from the United States and assembled in Brockville. The body of the car is manufactured at the local shops. The use of automobiles is rapidly increasing in this section, the moderate-priced car finding a ready sale.

Suburban Organizers Active—The Suburban Motor Car Company, of Detroit, Mich., is to begin operations at once on its factory at Ecorse, a new suburb which is 7 1-2 miles from city hall. The plant is to be entirely of reinforced concrete construction. The main structure will have a length of 400 feet and a width of 80 feet, the roof being of the sawtooth type. There are to be four side buildings, each being 60 feet by 400 feet. In front of these an administration building, 60 by 300 feet and two stories high, will be built after the factory has been completed. The power house will measure 150 by 200 feet, and it is planned to light the suburb by this plant as well as to furnish power for the factory. There will be no overhead shafting in the plant, the machinery to be driven by motors, in some cases these power units being for individual machines and in others for several in groups. Three cars have already been constructed, and twenty-five are to be put through the temporary plant immediately. While these are all four-cylinder types, it is planned to build both fours and sixes in the new factory.



Immense plant of the Schacht Motor Car Company, at Cincinnati, Ohio

Small Gasoline Vulcanizer; Cotton-Filled Mattress; Ingenious Belt Hinge; Mechanical Wheel; Nickel Polishing Compound; Lubricant Resisting All Temperatures; New Tire Iron; Latest Trade Literature

Diamond Tube Vulcanizer

A SMALL vulcanizer for use on the roadside is made by the Diamond Vulcanizer Company, 155 North High street, Columbus, O. This device, Fig. 1, is designed to repair punctures in tubes and comes in a box containing all the requisites to make a tube repair; the vulcanizer, a roll of patching rubber and cement to attach it to the tube. The vulcanizer proper is 6 by 5 1-2 by 2 1-2 inches and consists of two pieces of cast and machined metal, between which the tube is laid, the pieces being held together by two thumbscrews. The upper portion of the vulcanizer is shaped to form a small kettle into which gasoline or alcohol is poured until the space is nearly full of the fuel, which is then lighted. When the gasoline is burned out, the repair is finished, and the tube is ready to be replaced in the casing.

A certain amount of care is necessary in the operation of this vulcanizer, due to the use of gasoline as a source of the heat required in producing the tire repair. While gasoline is recommended for the work, it stands to reason that alcohol may be used in its place, which would naturally reduce the risks accompanying the use of the other fuel. In the combustion of the fuel the heat generated by the flame is largely absorbed by the vertical rib extensions of the vessel forming part of the vulcanizer, which transmits it to the rubber treated in the device.

White Swan Automobile Mattress

In Fig. 3 is seen the White Swan camping mattress for automobilists. It is made of tufted cotton felt, and is carried in shape of a roll. It comes in various sizes ranging from 2 feet to 3 1-2 feet in width, the length being standard at 6 feet 6 inches; the mattress weight varies from 16 to 25 pounds.

The compact size of the mattress when rolled together make it easy to find a suitable place for it in the car, where the passengers are not disturbed by its presence nor the mattress itself is in danger of being damaged. As the material which gives softness and spring to the mattress is cotton and not air under pressure, as in numerous other articles made for the same end, the punctures sometimes experienced with products of the latter sort are impossible.

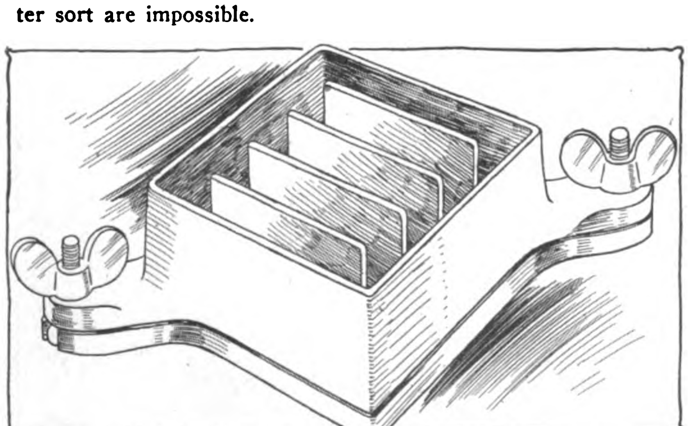


Fig. 1—Diamond vulcanizer heated by gasoline

Conn Fan Belt Hinge

An ingenious fan belt hinge for automobiles is the Conn type, shown in Fig. 2. Each hinge consists of seven pieces of hook-pointed steel wire which are bent in the upper left figure, and arranged on a steel pin which has a head on each end, keeping the wires tightly in place and preventing their coming off. When the hinge is put to use, every second wire is turned in an opposite direction from its neighboring two wires, giving the hinge the appearance seen at the right. The ends of the belt are then inserted between the upper and lower rows of points on each side of the hinge, after which the points of the hooked ends of the wires are hammered into the belt material. The Conn hinge is sold by Ash & Company, 1779 Broadway, New York City.

Bangs Coiled Spring Rim

E. D. Bangs, Milwaukee, Wis., makes a spring rim for the mounting of solid tires, which is used in connection with solid spokes. The wheel felloe is equipped with a number of coiled springs situated between the points where the spokes are attached to the felloe; the springs are contained in inverted cups fixed to the felloe and their free ends bear against the telescoping rim which floats in the felloe. This rim carries the solid tire, the method of attaching the latter to the rim being shown in the upper right corner of Fig. 3. The head of the bolt which holds rim and tire together extends into the open end of the spring cup and bears against the coiled spring. This arrangement has the following result: That when the tire strikes a road inequality, the shock is transmitted to the nearest one or two springs, where it is taken up in the form of spring compression or expansion which is released when the tire passes over a poor spot of the road.

Rex Nickel Polish Compound

The Arminger Chemical Company, Chicago, Ill., manufactures a new compound, the Rex Velvet Nickel Polish, which is specially adapted to prolong the life and luster of nickel plating on German silver. It is claimed by the maker that by the use of this polish the metal surfaces are not only kept brilliant but also receive a good cleaning when the material is applied, so that the strength of the plating is preserved. The polish is applied by means of a moist piece of cheesecloth or waste.

Western Gasoline and Oil Outfits

Complete storage equipment systems for gasoline and lubricants are manufactured by the Western Oil Pump & Storage Tank Company, St. Louis, Mo. The pumps have cylinders made of seamless brass; the pinions are of steel and the racks along which they travel are of malleable iron. Each pump is fitted with a measuring device registering every gallon drawn from the tank, and an automatic shut-off valve serves to positively interrupt the flow when pumping is stopped. The same company also manufactures cabinets in which the gasoline and oil equipment may be preferably stored. These cabinets are made of quartered oak with hammered copper trimmings, the doors being of beveled glass and the baseplates nickel lined.

Recent Trade Literature

IN its latest publication the National Motor Vehicle Company, Indianapolis, Ind., describes the details of Dawson's victory last Memorial Day. In addition thereto it also gives a number of records now held by National cars.

The Motorist's Handbook, brought out by the Michelin company, deals with the subject of repairing tire casings and inner tubes. The outfits manufactured for this purpose by the Michelin concern as well as the necessary operations are described in detail.

The *Reo Echo* of R. M. Owen & Company, Metropolitan dealers in Reo cars, is out. The summer number contains several interesting articles on farming and commercial uses of the automobile.

Tourists traveling through Maine this summer will find the roadbook of the Maine Automobile Association a useful addition to their equipment. The booklet contains a good map of automobile roads of the state of Maine and some text describing the touring ground found there.

Tractors are the principal subject treated in *Power and Efficiency,* a little journal published by the Waukesha Motor Company, Waukesha, Wis. It also takes up the special features of motors made by this company.

Fire truck tires are described in the small booklet which has but recently been printed for the Goodyear Tire & Rubber Company, Akron, O.; it contains descriptions and illustrations of single and dual equipment of the solid-tire class.

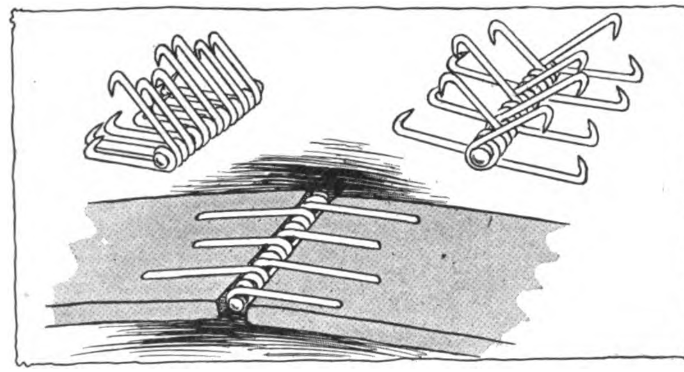

Fig. 2—Conn automobile fan bolt hinge

Pencils and lubricants fill most of the pages of *Graphite,* the house organ of the Joseph Dixon Crucible Company, Jersey City, N. J.

The July number of *Lozier Logic* is full of interesting history pertaining to the racing victories of the Plattsburg-Detroit product. Among other features a description of the last Fairmount Park races, in which the Lozier cars were among the early finishers, is of special interest.

The Cadillaqua festival recently celebrated in Detroit is the subject of a small pamphlet received by our office. Interesting details of the history of the great automobile center of Michigan and of the men that built it make the attractive booklet animated reading matter.

Parties interested in the makeup of an effective pamphlet will do well to procure a copy of the booklet *From Wool to Cloth,* which is being distributed by the American Woolen Company, Boston, Mass. The subject of the booklet is the manufacture of woolen goods, the whole process of making the finished product from the raw material being described in simple and interesting language.

The subject of solid rubber tires for hand-trucks is taken up in the latest booklet of the Goodyear Tire & Rubber Company, the designs of the various sizes of tires being illustrated by sectional views elucidating the various features of the products of the Goodyear company.

Automobilists interested in axles will find the attractive booklet of the Timken Detroit Axle Company an instructive piece of literature. This work describes the functions of automobile axles and explains the office of each part thereof in a manner which will greatly help the average owner to understand the anatomy of his car and call his attention to the care demanded by its various parts.

The Timken Roller Bearing Company, Canton O., has just published a little book on the *Care and Character of Bearings,* in which the construction of roller bearings is described in detail. The subject is one of interest to all automobilists and upon writing to the company any reader may obtain a copy of this booklet.

Harrison Agalite Lubricant

A lubricant for transmission, axle and bearing service, which is claimed not to congeal in cold weather or become thin in summer, is made by the Harrison Agalite Non-Fluid Lubrication Company, Inc., Syracuse, N. Y. The consistency of Agalite is said to be such that no grease which is placed in the differential can make its way to the brake drums, which would result in brake slippage. The lubricant, according to the maker, does not melt even when heated to a temperature as high as 200 degees Fahrenheit, but proves equally efficient a lubricant as at lower temperatures.

Three-Way Q. D. Tire Iron

The Brookline Motor & Specialty Corporation, 5 Pearl street, Brookline, Mass., is the maker of a simple device which serves for the removal of tires from Q. D. rims, especially when the tire has become rusted to the rim. Three parts constitute this tool; a handle, a hook which engages the outer bead and two wedges by means of which the tire is forced off the rim. The leverage of the handle is sufficient to make the work or taking the tire off its rim easy even when it has a rigid hold upon the latter. A screw which fits into any one of a number of holes on the handle permits of adjusting the iron for use on tires of different sizes.

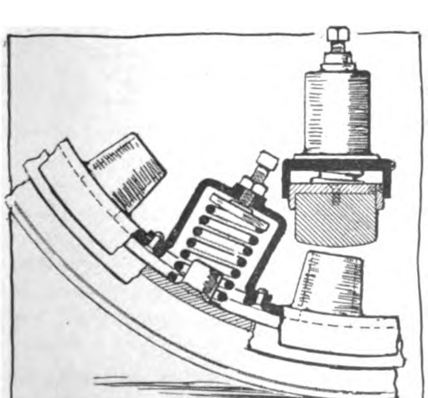

Fig. 3—Bangs coiled spring rim

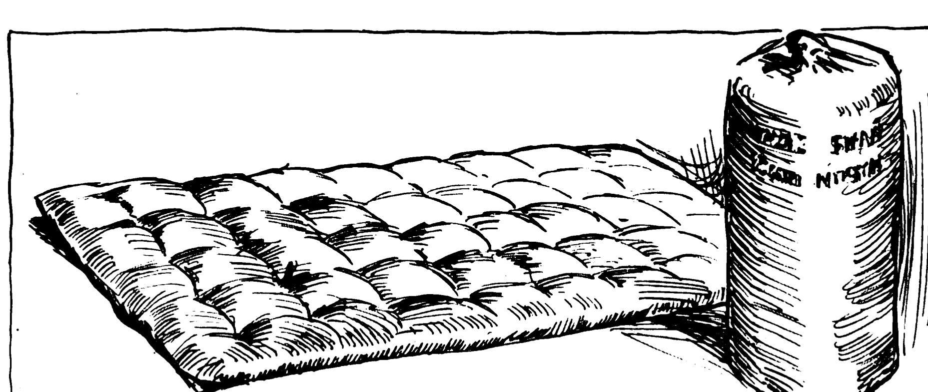

Fig. 4—White Swan tufted-cotton mattress

INTERNAL-COMBUSTION **Motor Valve**—Being a rotary cylinder in the head pressed tightly against the cylinder port by the pressure of the gas in the combustion chamber of the motor.

This patent relates to a rotary cylinder valve V in an engine construction, Fig. 1, which is encased in the head of the working cylinder. One side of the valve faces the cylinder port P serving for inlet and exhaust of the gases, and the other side of the valve is supported by and bears against a shoe S which is pressed against the valve by a piston P1. This piston is subject to the gas pressure existing in the working cylinder, being contained in a space which communicates with the combustion chamber by a passageway W. The valve is adapted to serve as inlet and exhaust valve, by making alternate connection between the interior of the cylinder and the respective manifolds.

No. 4,164 British—to J. Irigny Baverey, Rhone, France. Filed February 18, 1912. Granted June 12, 1912.

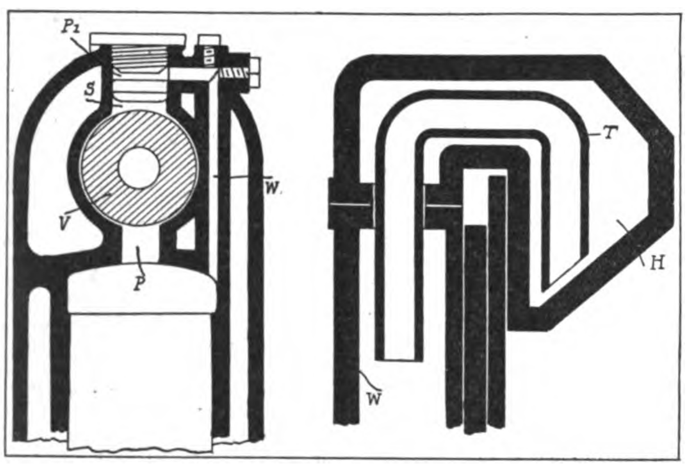

Fig. 1—Baverey rotary valve. Fig. 2—Philip-Reissig Jacket Syphon Idea

Cooling of Explosion Motors—Being a system of draining the head jackets of motors which are cast with jackets separate from those surrounding the cylinder walls.

The subject matter of this patent is illustrated in Fig. 2, showing the cooling of an engine of the Knight type, where the water-cooled cylinder head has an inwardly projecting extension forming a water pocket for the cooling of the head. The use of the tube T presents a means of communication between the jacket extension H which serves to cool the head and the space W of the water jacket cooling the cylinder walls. In draining the water from W, the tube T has the effect of a syphon, permitting the space H to be drained at the same time.

No. 5,406 British—to D. Philip and O. Reissig, Charlottenburg, Germany. Granted June 26, 1912; filed March 3, 1912.

Lamp-Turning Device—Which serves to swivel the headlights in the same direction as the front wheels of the car, the degree of turning the headlights being adjustable by the drive.

This patent describes a construction, Figs. 3 to 6, by means of which the headlights of a car are turned in the same direction as the front wheels when the latter are actuated. The mechanism operating the lights consists of a sleeve S surrounding the steering post, a lever L operating it, a set of gears G, G1, which transmit the rotative movement of the sleeve to the sleeve S2 equipped with an arm A holding the lever L1, Fig. 4. As L1 is turned around the ideal axis of sleeve S2, the rod R is drawn forward or backward, thereby turning one of the headlights to one side of the other. The connection C1 which attaches this headlight to its mate causes the latter to swivel in the same way as the first light.

The lever L is pressed by a spring against the stop S1 on the steering wheel, whereby the lamps are normally held so as to illuminate the path of the car when traveling straight ahead. The lever L1 is adjustable in the arm A, so that the amount of swiveling caused by turning the steering wheel through a fixed angle may be altered. Lost motion in the steering gear is compensated for by the lost-motion device contained in the rod R and shown in detail in Fig. 6. This takeup device consists of a piston R3 moving between two stops R2 in the tubular part R1 of the rod R. The method of securing the lamp holders to the car without boring holes in the chassis frame is clearly shown in one of the smaller illustrations, Fig. 3, where a link L2 is provided with three flanges M1, M2 and M3 and pointed screws S4 which bear against the outer edge of the frame. A screw S3 holds the flange M2 to the opposite side of the frame; a plug is inserted between M3 and the curved frame surface.

No. 5,453 British—to O. Riemann, Chemnitz-Coblenz, Germany. Granted June 26, 1912; filed March 4, 1912.

Vehicle Wheel Attachment—A method for locking wire wheels on the hubs by means of a nut and a cap.

In the construction, Fig. 7, a nut N serves to secure a detachable wire wheel to a hub H. The nut is locked by a bar B which may be used to rotate it and is pivoted at P. A cap C engages a thread on the hub, which is different from that carrying the nut N; this cap has a diametrical groove which engages the bar designed to lock the nut. The bar is held down and in position by spring-pressed pins Q which it carries and which engage a hole in the boss B1, Fig. 8.

No. 5,590 British—to L. Girardot, Paris, France. Granted June 26, 1912; filed March 6, 1912.

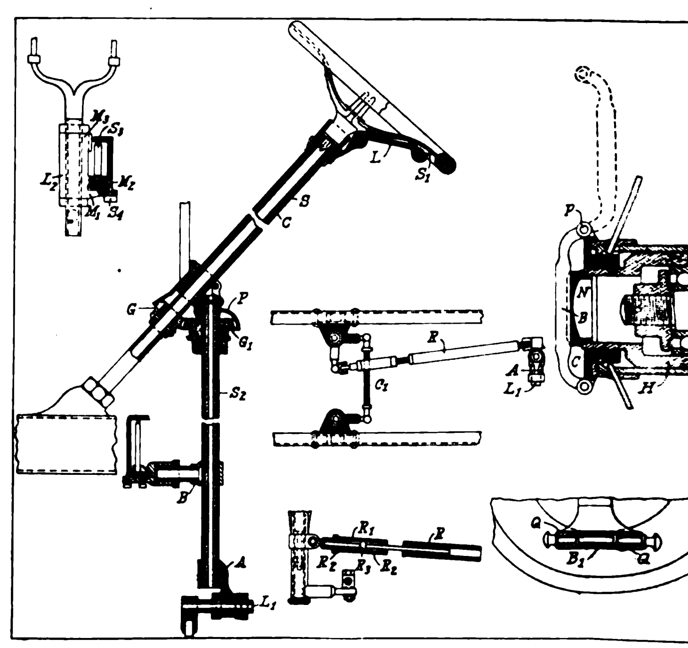

Fig. 3—Lamp attachment of Riemann device. Fig. 4—Construction of lamp-turning mechanism. Fig. 5—Link connection between mechanism and lamps. Fig. 6—Lost-motion takeup device. Fig. 7—Girardot wheel attachment. Fig. 8—Locking feature of same

Vol. XXVII New York—Thursday, August 8, 1912—Chicago No. 6

The Automobile

Increasing Brake Efficiency; Proper Methods of Application

Locking the Wheels Detrimental to Tires—Gradual Retardation Gives the Best Results—Full Brake Power Seldom Required—Opinions of Factory Experts

Technical Phase of the Subject—Best of Materials Requisite—Study of Friction Coefficients—Arguments For and Against Metal and Fabric Facings—Results of the Tests

STOPPING a car without applying enough pressure on the brakes to lock the wheels is the most efficient braking method. It is also the cheapest to the owner—In official brake tests conducted during the past 3 years after long-distance reliability contests the best brakes have been those in which the rear wheels were not locked. In such cases the cars have been stopped in the shortest distances. In not a few of these tests where a contestant has been given two successive trials better results have been obtained in the second trial by momentarily releasing the brake after the wheel was locked and then applying it again than were obtained in the first trial, where the wheel was locked from the second of brake application.

In all of these brake trials with cars traveling at 20 and 18 miles per hour when crossing the line at which the brakes had to be applied, the two rear wheels were locked and skidded towards the curb, so that when the car finally stopped it was at an angle of 45 degrees across the street. Such conditions have happened on dry asphalt pavement and also on some types of bitumen road surfaces.

Practically all of these brake tests called for stopping the car within a distance of 50 feet without penalization, and a penalty of one point per foot was imposed for every foot over the 50 required in stopping. In these tests many drivers were able to skid the wheels for 20 or 30 feet before crossing the 50-foot line, but still were compelled to take a penalty of a point or more, whereas others who did not lock the wheels stopped in distances of 28 to 40 feet.

RESULTS OF OFFICIAL BRAKE TESTS, WITH CAR TRAVELING AT 20 MILES AN HOUR

Car weight	Service brake	Emergency brake
3,740 pounds	32 feet	30 feet
3,900 "	33 "	33 "
3,750 "	36 "	30 "
4,280 "	55 "	22 "
4,090 "	45 "	40 "
3,790 "	38 "	68 "
4,260 "	97 "	39 "
6,030 "	27 "	35 "
3,750 "	23 "	28 "
3,340 "	31 "	28 "
3,450 "	29 "	49 "
3,620 "	39 "	53 "
3,490 "	61 "	46 "
3,830 "	31 "	30 "
4,010 "	63 "	40 "

These examples proved conclusively that locking the wheel is not enough; the brake must do more. The brake designer must keep this in mind in designing his braking arrangements; the manufacturer of brake facing materials must also keep it in mind and the driver must realize that he is not getting the maximum efficiency out of his brakes when he merely locks the wheels and permits the car to skid wherever it may.

When the wheels are locked the tire has to slide instead of roll over the road surface, and the actual possible retarding power of the tire is discounted in that one small portion of the tire surface does the work and it invariably becomes quickly glazed by dust or other matter accumulated from the street during the slipping or skidding, and which matter reduces the adhesion between the tire and the street surface. As already stated, better results and shorter stops have been made by momentarily releasing the brake after a short skid due to a new portion of the tire tread being brought into use, this portion not being glazed at the moment of application. Where a brake is designed to give gradual retardation instead of the instantaneous lock this factor is eliminated and the entire circumference of the tire is brought in contact with the road surface, there is not an opportunity for the glazing, with the consequent result of a quicker stop.

Automobile owners are constantly asking for the distance in which the car should stop from the moment of brake application. It is impossible to answer this question. The answer depends on the surface materials of the road, on the moisture element in the surface, on the car brakes, the car weight and the method of application. Some accurate figures are given herewith, these being taken from official tests with the car traveling at 20 miles per hour with two passengers and full equipment on. These distances range from 27 to 97 feet. In order to make the facts more valuable the car weights are given. In each case the tests were on level asphalt and the speeds full 20 miles. One set of brakes was applied at a time, the service or foot brakes first and the emergency or lever brakes second. It must be borne in mind that these tests were made after approximately 1,000 miles or road use with full load and at an average speed of 20 miles per hour schedule.

The figures show that a good brake should stop a car within 35 feet, one set used only. Brake engineers differ on this subject. "We believe that when the average car is traveling on smooth asphalt the brakes should be so constructed and so lined as to bring the car to a stop within 28 feet at 20 miles an hour, using both brakes at once," states J. R. Kelso, general manager of the Woven Steel Rubber Company.

Never Use Full Brake Power

Most brakes will readily fulfill these conditions when the cars leave the factory, but when the owner neglects the care of the brakes after the car is delivered to him, the efficiency rapidly falls off until he is suddenly made aware of existing conditions by the brakes failing him in an emergency where a quick stop is a necessity. A gradual stop is desirable; a sudden stop shortens the life of the brakes and tires. To use the brakes only when necessary is an excellent practice.

In descending a steep hill let the motor be the brake. Throw the gearset into second or third speed if the hill is very steep. Switch off the ignition and let in the clutch. The car will be practically driving an air compressor, saving the brakes and cooling off the motor. Near the bottom of the hill turn on the switch. In most cases it will be unnecessary to touch the brakes.

Before looking at the brake problem from the manufacturer's standpoint a few points of vital interest to the owner may be touched upon. The car should never be voluntarily driven into such a position where a sudden stop by the use of the utmost possible braking power is necessary. The brake lining will be rapidly worn away if this is done, necessitating an adjustment of the brake at frequent intervals. In hilly country brakes will require an adjustment after from 600 to 800 miles' use on an average car, while in level country they will only need regulating after between 3,000 and 4,000 miles of travel.

The figures apply to fabric-lined brakes, but with metal-faced types only a few users of such claim 15,000 miles' service in hilly countries without an adjustment. This freedom from adjustment is advanced by them as the strongest argument for the metal facing. While advancing these figures they also admit that the friction qualities of the metal are not equal to those of the fabric composition, and also that the brake is not so quiet in operation. There are others who use both metal and friction facings, metal on one set and friction on the other, the use of two materials being due to the different qualities of them, and so providing the driver with a higher safety factor than were a single material used. Some strike a half-way mark, using metal and fabric on the same brake, using soft iron segments with short segments of fabric between them, the iron being inserted to prevent the brake from glazing, and so giving a more efficient brake construction.

"A good brake lining must have four qualifications," says G. W. Dunham, consulting engineer of the Chalmers Motor Company. "First, it must be thoroughly heat-resisting; second, able to stand rough usage with a minimum amount of wear; third, it must not grab, and fourth, it must be silent in action." This statement is typical of the requirements of the manufacturer. According to the same authority, "If a brake fulfills these conditions it should hold the wheels just short of skidding which will give a stop in a minimum distance considering the weight of the car, the load carried and the conditions of the road. Any of the brakes provided on the cars of today are sufficient to lock the wheels, but the desirable feature, aside from stopping the wheels under all conditions is to allow them to turn very slowly."

There are two ways of stopping a car. One is by locking the wheels and skidding and the other is by allowing the wheels to turn and interposing the resistance on the brake drums requiring the momentum of the car to overcome the resistance there instead of expending its force in sliding the tires over the road surface. The first method wears tires and the second wears the brake material. Brake fabric is cheaper than tires and the answer to the question as to which is the best way to stop a car seems obvious.

Taking the testimony of the experts employed in the largest motor car manufacturing plants the conclusion which is reached immediately is that the most efficient stop is made when the force exerted on the wheels is just below the point where locking takes place and a skidding stop is made. The wheels are allowed to roll over the ground and a smooth silent stop is made. Putting the tire casing against a swiftly revolving grindstone will scarcely destroy it more quickly than allowing it to slide over the gritty surface of a road, but a stop made by not skidding will be accomplished in less distance, will minimize the stresses on the tire fabric, reduce the tendency toward side slipping and be far easier on the wheel itself. These are the reasons advancd by the designers for their declaration as to the best way to stop a moving automobile and in the light of this it is interesting to note what the engineers are doing to provide a braking outfit that will act in such a way that an ideal stop is made.

The matter of designing the braking system of a car is up to two distinct parties: The first is the manufacturer of the brake material and the second is the car manufacturer who designs the system of application and what is just as important, the system of compensation for the wear that must occur in the fabric. The producer of the brake material must bring out an article which will have above all a high coefficient of friction. As it is generally understood this coefficient is an expression showing the definite relation between the force required to just move a given load over a surface and the weight of that load. Where the pull required to move the load is P pounds and the weight is W pounds an expression involving the coefficient of friction f, would be $P = fW$. To illustrate: If a 10-pound pull were required to just move a load of 100 pounds weight over a given surface the equation would become $10 = f\ 100$. Solving, $f = .10$. In the case of the brake the load is the pressure applied by the driver, the coefficient of friction depends on the nature of the braking surface and the product of the two gives the pull as expressed above by P and this is the force that is exerted by the brakes in bringing the car to a stop.

High Friction Coefficient Necessary

The fabrics used for brake linings are composed to a large extent of asbestos fabric stranded with brass or copper wire which varies all the way, according to the claims of the makers and users from .25 to .90. Taking .60 as a probable average to further illustrate the meaning of the coefficient of friction as distinctly applied to the brakes of an automobile, the effect of the ordinary application of a brake will be noted:

When the driver presses his foot upon the pedal he sets in motion a system of levers and a cam on the brake which reduce the distance through which the different members of the system travel but which magnify the power to a large extent. Assuming for the moment that the pressure exerted upon the pedal results in a pressure of 1,000 pounds at the point of application of the brake to the drum, this will correspond to a load of 1,000 pounds pressing the brake fabric against the drum. The resulting friction will be the product of this load and the coefficient of friction, .60 making such product 600 pounds. This pressure is exerted at the rim of the brake drum which may be assumed to be a distance of 9 inches from the center of the axle and when referred to this point result in a stopping or retarding moment of 1,500 inch-pounds which is opposed to the moving car and which gradually brings it to rest.

It is evident then that the maker of the brake lining must make a high coefficient of friction an aim if he wishes his fabric to be a success, because where the coefficient of friction is low only a small percentage of the load applied to the brakes by the pressure of foot or hand is utilized in producing a stopping moment which after all is the final aim of any braking system.

Brake material must be able to resist the effects of a high temperature. There is a law of nature which says that no energy can be destroyed, it may change its form but it will never cease to exist. The energy which is stored up in a moving car must be dissipated gradually in bringing the car to rest and in doing this a large part of it is transformed into heat. The temperature at which most brakes are tested is at a dull red heat of iron. Other makers require that the material shall show no change of structure when submitted to a temperature of 800 degrees Fahrenheit. Should brake material char its integrity will be destroyed to such an extent that it will literally fall apart so that this heat-resisting quality is an absolute necessity. Some of the statements made by experts in the manufacture of brake linings may be repeated to show the importance in which temperature resisting qualities are held:

George D. Moore, president of the Standard Woven Fabric Company says: "The temperature which a brake lining should be capable of standing should be as high as a dull red heat. I have seen instances of brakes which have been run at temperatures quite as high as this."

I. A. Venters, speaking for the Johns-Manville Company declares that, "Any good surfacing material should be capable of withstanding a temperature of 800 degrees Fahrenheit."

Brake material must resist the effects of oil and water. If the material should absorb oil readily it would become useless in a short time because the coefficient of friction would be lowered to such an extent that it would be impossible to stop the car in a short enough distance. On the other hand it must not be so full of oil or other compounds that said oil or compound will run out when the band becomes extremely hot on account of the friction when the brake is applied. Oil is prone to work its way through the rear axle and out to the brake drums on many cars. Felt washers and packing boxes of various kinds have been used with success but after a time when wear has taken place the surface of the brakes is apt to acquire a slippery coating of lubricant which renders the brakes inefficient until they are washed off with gasoline. A renewal of the felt washers prevents the recurrence of a trouble of this nature.

Linings Must Be of Best Quality

The maker is exacting in his requirements of the brake lining manufacture because he is aware that, should it not possess ample wearing qualities, numerous replacements will be necessary. What the car maker requires is of great importance because it brings out better than anything else what the requirements of a good brake should be. An example of what automobile engineers consider as important in a brake may be mentioned: Speaking for the Pierce-Arrow Motor Car Company, D. Fergusson, chief engineer, has this to say: "The lining should not be compressible, otherwise the brakes will have to be frequently adjusted. Many brake linings require more taking up for this cause than for actual wear. They should not wear rapidly. The material should have sufficient tensile strength so as not to be torn away from its fastenings. The lining should be fireproof and if of metal should have a high melting point. The lining should be capable of being readily renewed. The punching of holes through it should not open up the seams."

"As a general proposition the brake capacity in all cars, both American and foreign for use in this country is inadequate," says W. A. Drysdale, consulting engineer for the American Asbestos Company.

"It is our impression that the brake capacity of the average American car for extreme use is rather under than over the proper requirements," says George D. Moore, president of the Standard Woven Fabric Company.

"The braking capacity of the average car is either not up to the standard, or else the average driver is very lax in the care of his brake," states I. A. Venters, of the Johns-Manville Company.

"We think that while many cars in the past had insufficient braking capacity, that the present tendency is to correct this trouble," says J. R. Kelso, general manager of the Woven Steel Hose & Rubber Company.

Speaking again, D. Ferguson says, "If the brake drum diameters are too large, the chances of locking the wheels are very great with even a moderate pressure applied to the levers. The proportion of leverage and brake drum diameter should be such that it requires considerable effort to lock the wheels, otherwise the tires will not last long."

There is a point evidently where these two extremes meet to produce the brake that will give the efficient stop noted before. It is the office of the maker of the brake material whether it be a copper or brass-asbestos fabric or a metal, to produce something which will meet the frictional requirements, have a high heat-resisting capacity, good conductivity, long-wearing qualities, good tensile strength, easily removed and renewed, silence in action, it must not grab, it must not absorb oil or water and it must be incompressible.

The car manufacturers must produce a system by which a gradual pressure can be put upon the brakes, the drum areas must be correct, the fabric must be ordered thick enough, the brakes must be readily adjustable with adjusting points above all accessible, the brakes must not be allowed to drag, it must be easy to get at the brakes to reline them and the drums must be of such material that they will not wear.

French Automobile Exports Gain

Paris, July 26—An increase in exports of more than $4,000,000, and a very slight increase in imports, with the United States still standing firm, are the outstanding features of the French automobile returns for the first six months of 1912. During the half year automobile imports rose to the sum of $1,337,940, compared with $1,316,940 for the same period of 1911.

The French national industry has every reason to be satisfied with volume of business done during the half year, for the actual increase, compared with the first six months of 1911, totals $4,155,180. Increased business has been done with England, Belgium, Germany, Switzerland, United States, Brazil, Argentine Republic, and Algeria. The most important feature of the foreign trade is the great increase with Belgium. From $2,747,640 in the first half of 1911, the volume of business has increased to $4,330,320 during the current half year. Great Britain still stands at the head of the list as the most important customer of France, but the increased trade with her has been very slight, and the total with Belgium comes close to that with England. The following are the official figures of French automobile exports for the first six months of 1912:

	Half year 1912	Half year 1911
Great Britain	$5,932,380	$5,835,480
Belgium	4,330,320	2,747,640
Germany	1,687,920	1,308,240
Argentine Republic	1,515,800	899,400
Algeria	1,477,260	1,021,320
Brazil	987,120	675,120
Switzerland	540,840	441,480
United States	543,180	295,500
Italy	445,880	527,040
Spain	333,340	252,540
Russia	178,140	262,800
Austria	108,540	230,760
Turkey	85,740	237,240
Other countries	2,195,160	1,471,980
	$20,361,720	$16,206,540

Legal News of the Week

Details of Knight vs. Argyll Suit, in Which Court Decided That Latter Had Not Infringed

Agent Can Sell All Types of Horns—Hupmobile Representative Bankrupt—Wishart-Dayton Bankrupt

LONDON, July 26—Further particulars regarding the adverse decision in the litigation commenced by Charles Y. Knight and associates against the Society of Motor Manufacturers and Traders involving the alleged infringement of the Knight patent in the Argyll single-sleeve valve engine have come to public notice.

The plaintiffs, Charles Knight and Lyman B. Kilbourne, were the registered legal owners of letters patent dated July 15, 1905, and numbered 14,729, for an invention of internal combustion engines granted to the plaintiffs for the term of 14 years from the date thereof; and the complete specification of the letters patent was duly amended by an order of the Chief Examiner dated November 16, 1908. The plaintiffs alleged that the defendants had infringed their letters patent, and they claimed an injunction and the usual consequential relief.

The plaintiffs' engine was used in the Daimler cars, and they complained in particular of the exposure and offering for sale at the defendants' stand at the show held by the Society of Motor Manufacturers and Traders (Limited) at Olympia, on November 3, 1911, of a 25-horsepower engine fitted to a limousine car and described as the "Argyll single-sleeve valve engine." The defendants denied the alleged infringement and the validity of the plaintiffs' letters patent. They also set up the usual defenses of anticipation and want of novelty, and alleged that the invention was not useful.

The trial of the action occupied several days as reported in *The Times* of July 4, and at the conclusion of the evidence and arguments judgment was reserved.

Claims of the Inventor

Mr. Justice Neville, in the course of his judgment said, that to claim for the patent for this invention the title of a master patent was, he thought, extravagant. The inventors declared the primary object of their invention to be to provide an improved form of internal combustion engine in which the moving parts should be directly connected and positively acting and the use of poppet valves and springs avoided. They declared that the invention consisted in certain features of novelty in the construction, combination, and arrangement of parts, all as fully described and more particularly pointed out in the claims. They then enumerated the parts and declared that either the cylinder described or a member telescoped with it should be operatively connected with the piston, but so far the court had not been told which of those parts was to be moved, the invention being in effect declared to be compatible with the movement of either. They then proceeded to tell the court that in the exemplification of the invention shown in the drawings of the two telescoped parts the cylinder was the one to be moved.

His lordship thought as a matter of construction that the exemplification was an exemplification in which one of two alternatives was adopted, but that subject to that the succeeding parts of the specification describe the invention itself, and not merely one way of carrying it into effect.

The present case showed the great care which should be exercised in allowing amendments to the claims in a specification, particularly where there was no opposition. The comptroller was doubtless told, as his lordship had been told, that the alteration was merely a verbal one, but clearly it could not have been intended to narrow the claim. It was, therefore, either wholly immaterial and should have been disallowed on that ground, or it must have been intended to widen the claim and was therefore illegal. In the result it had in the present action been relied upon in effect as altering a claim of an obviously limited character into one of the widest possible extent, and his lordship's conclusion was that upon the true construction of the specification the defendants had not infringed.

It appeared to his lordship that the action was a somewhat audacious attempt to resuscitate a patent for an invention of small compass and, to say the most of it, of very moderate utility, and by the help of an amendment to make it cover and embrace a wide field of enterprise in a comparatively modern type of mechanism, and so far as he was concerned the attempt failed and he dismissed the action with costs.

An appeal has been entered.

Hupmobile Agent Bankrupt

WASHINGTON, D. C., Aug. 6—An involuntary petition in bankruptcy was today filed against one Reed, the local agent for the Hupmobile. The Mutual Automobile Accessories Company, $28; Crane Wagner, Incorporated, $255, and Fox Stiefel & Company, $725.83, were the petitioners. Reed opened his shop several months ago at 1218 Connecticut avenue, in the heart of the fashionable residence district and looked to have a bright future. L. C. Loving and T. C. Bradley, were appointed receivers under a bond of $5,000.

The Diamond Rubber Company secured judgment against Reed for $310 and the Lovell McConnell Manufacturing Company filed suit against him for $230. Reed's total liabilities are about $6,500 and his assets $1,500.

Palmer & Singer to Appeal

According to Jay N. Emley, solicitor for the Palmer & Singer Manufacturing Company, a motion will be made in the United States District Court in the immediate future to vacate the order of Judge Hand providing for a decree *pro confesso* in the suit instituted last fall by the Enterprize Automobile Company for alleged infringement of the Dyer patents.

Mr. Emley asserts that the demurrer filed by him prior to the ruling of the court was not included in the presentation for decree *pro confesso* by the solicitors for the Enterprize Automobile Company, Dyer, Dyer & Taylor, and the latter hold that the various postponements and delays which have occurred from time to time did not contemplate the filing of any demurrer at all.

Can Sell All Types of Horns

PROVIDENCE, R. I., Aug. 5—Judge Brown of the United States District Court, for the District of Rhode Island, has denied the application of the Lovell-McConnell Manufacturing Company and others for an injunction to prevent the Waite Auto Supply Company from dealing in Newtone horns and from dealing in Klaxon and Klaxonet horns or from dealing in Newtone horns while at the same time dealing in Klaxon and Klaxonet horns.

Affidavits were presented on both sides and arguments were made from both points of view. J. Jerome Hahn, solicitor for the defendant company, moved that the application be denied and on July 29 the court held and ordered that the motion for injunction be denied. The main contentions will be tried out upon final hearing which will probably be had early in the Fall.

Must Appear in Court in Person

MALDEN, MASS., Aug. 5—Judge Bruce of the district court has read a lecture to the police of this city for assuming to tell motorists arrested for speeding that they could enter an appearance through their attorneys instead of appearing themselves and plead *nono nolo contendre*. The men so notified were ordered to appear before the judge so that he could hear what they had to say, as he believes that in making them come into a court of justice the seriousness of their offense will be impressed upon them more forcibly and they may be more careful in future. That the judge if fair was shown by his disposition on a case last week when a motorist whose car swung off the road a few feet and ran on the grass of the parkway was arrested on a charge of reckless driving. The judge discharged the man and told the arresting officer that there was no ground for such a complaint, explaining that reckless driving meant speeding at a rate that endangered the lives of people.

Rose-Grossman Suit Nearing Trial

In the suit of Rose Manufacturing Company against Emil Grossman and others the plea made by Charles C. Gill, solicitor for the defendant, has been withdrawn and leave to file an answer on the September rule day has been granted. The suit involves the validity of the Neverout license plate holder patent held by the Rose company. The plea that had been entered by Mr. Gill was that the claims set out in the petition had already been adjudicated. This plea is now withdrawn and an answer to all the material allegations will be filed.

Receiver Appointed for Madison

BALTIMORE, MD., Aug. 5—A receiver has been appointed for the Madison Motor Car Company by Judge Dawkins in Circuit Court. The bill of complaint was filed by Pinckney L. Sothoron, who states that he is a stockholder of the company, having twenty-five shares at $100 a share. The company consented to having J. Milton Lyell appointed receiver and permission was granted to the receiver to continue the business for 60 days.

Wishart-Dayton in Difficulties

Involuntary bankruptcy proceedings have been instituted in the United States District Court against the Wishart-Dayton Automobile Company which handled trucks in New York. The liabilities are estimated at $10,000 and the assets at half that amount. Spencer E. Wishart, the well-known race driver, was formerly connected with the embarrassed concern.

Goodyear to Sell $1,600,000 Stock

The Goodyear Tire and Rubber Company, of Akron, Ohio, is marketing the remainder of its authorized issue of $5,000,000 of 7 per cent. cumulative preferred stock through Spencer Trask & Company, of New York. Delivery of the new certificates will begin after September 1, according to the brokers.

The total amount to be disposed of aggregates about $1,600,000 and the market has stood above par for a long time on this issue. The circular issued by Spencer Trask & Company shows that 80 per cent. of the total output of the company consists of pneumatic tires and the estimated gross earnings for the fiscal year ending October 31, 1912, will be in the neighborhood of $25,000,000 with net applicable to dividends of $2,500,000. According to the balance sheet submitted in summarized form, the assets of the company amount to 200.6 per cent. on the preferred stock issue and 138.4 per cent. of quick assets.

THE following individual licenses have been granted by the Enterprize Automobile Company, authorizing the use of the Dyer transmission patents: To Joseph G. Fornecker, Sultan; Washington Garage, Sultan; William Scully, Sultan; Bruno Schultz, Rochet-Schneider; S. H. Bergs, Dragon; Jacob Hardtfelder, Allen-Kingston; Kelsey Smith, G. J. G.; Gustave Weyl, Cortland; Thomas Wilmarth, Mora; Thomas Callahan, Sultan; Andrew Lebrasseur, Mors; F. M. Rahill, G. J. G.; Melrose Garage, C. G. V.; Joseph Sperker, Sultan and William Whitman, Isotta.

Allen Brothers, American agents for the Metallurgique line, have taken out an importers license under the patents.

Willys Alleges Fraud

In Suit Against Officials of Gramm Company Avers They Voted Themselves Stock Illegally

Divided Surplus That Did Not Exist—Weed Chain Tire Grip Company Wins Two Suits

TOLEDO, O., Aug. 4—A sensational suit was this week filed in the common pleas court, by John N. Willys against A. L. White, president, and W. T. Agester, treasurer, of the Gramm Motor Truck Company, of Lima, O., asking the court to set aside a contract entered into last April on grounds of fraud. Mr. Willys alleges that on last April 15 he was induced by certain representations on the part of defendants, to enter into an agreement whereby he was to purchase 4,000 shares of the stock of the Gramm company at its par value. That he paid to defendants the sum of $50,000 in cash and gave his promissory notes due one for $75,000 on August 1, one for $75,000 due on September 1, one for $100,000 due on October 1, and one for $100,000 due on November 1. He alleges that the notes and stock were deposited in the National Bank of Commerce, at Toledo, O., which is also made a party defendant. Willys claims that at a meeting of the stockholders of the Gramm company, held last September, and controlled by White and Agester, the company was authorized to deliver to the A. C. W. Realty Company 1,000 shares of stock, for a fictitious indebtedness, and caused the company to issue a delivery certificate, dated August 1, 1911, without receiving any compensation therefor. It is claimed that Ira B. Carns, a stockholder in the Gramm company, controls this concern. It is further alleged by Mr. Willys that at the same meeting a dividend of $225,000 was declared payable in stock, and a division of stock was authorized when the company had no surplus capital. Shares were then distributed to the number of 750 to the A. W. C. Realty Company, 221 to A. L. White, 150 to W. T. Agester and 196 to I. B Carns, making a total of 1,142 shares. Willys alleges that White and Agester then voted to themselves respectively 755 and 800 shares of the common stock of the concern, and that the whole amount of 4,000 shares was then sold to him at par. He states that the company had no surplus to divide but had lost large sums; that it had no legal right to any real estate, but that it occupied the plant under a contract to purchase the property, and that it is indebted in the sum of about $135,000, none of which facts were made known to him at the time of purchase. He asks the court to grant the relief denied by defendants; that his notes be returned to him; that the contract be annulled; and that he may recover $50,000 already paid.

Weed Company Wins Two Suits

Final decrees in the suits for infringement of the Parsons non-skid patent have been entered in the United States District Court against the Newhall company and the Seneca Chain Company on application of the Weed Chain Tire Grip Company.

The last step in these prosecutions was not contested and the decrees were by consent of the defendants.

RICHMOND, VA., Aug. 3—Among the 121 indictments returned by a grand jury in the Hustings Court against firms and corporations failing to pay State license taxes appear the following:

Jefferson Garage, E. H. and N. W. Christian, proprietors; Diamond Rubber Company, of New York, R. G. Dunn, manager; Ford Auto Company, R. F. Kochler, manager; Thomas Motor Sales Company, O. B. White, proprietor; United Rubber and Tire Company, F. B. Goodloe, manager.

Atlas Deal Declared Off

Everitt People Object to Flanders Using His Name in Connection With New Company

Studebaker Corporation Drops Names of E-M-F and Flanders—Will Use Own Name for All Models

CHICAGO, Aug. 3—The deal between Normon W. Church, of Los Angeles, Cal., and Walter E. Flanders, of Detroit, in connection with the bid for the plant of the Atlas Engine Works, of Indianapolis, has been called off and following this announcement Mr. Church has told of the negotiations which, it was expected, would result in the purchase of the Atlas Engine Works and the occupation of the big factory of the Flanders Motor Car Company, which was to have been organized for the purpose of turning out a car to sell at $1,000 or under.

"About May 1," said Mr. Church, "information reached me through banking interests that it would be possible to secure control of the Atlas plant. I knew the factory and its possibilities and I realized what a big thing it would be to get it and turn it into a factory for the production of cheap cars. I first of all talked to W. F. McGuire, then factory superintendent of the Ford Motor Company, of Detroit, and he, too, saw the opportunities. Then we determined to interest Walter E. Flanders, the three of us to swing the deal. Mr. Flanders was agreeable and we proceeded with our plans.

"We determined to use the Flanders prestige to the utmost and decided to call the new concern the Flanders Motor Car Company, Mr. Flanders having discovered that his Studebaker contract did not stop him using his name in other businesses. This was after he had gone into the Everitt deal. When he joined the latter combination he was under the impression that his hands were tied so far as using his name was concerned.

"Investigating affairs at the Atlas plant, we found that it would be necessary to put the concern through a friendly bankruptcy, which was done, and we were prepared to close the deal at the receiver's sale which was held last Monday. I was called from Los Angeles and when I got East I found that the Everitt people had raised an objection to Flanders using his name for the company I was forming, claiming that it was doing them an injustice and robbing them of prestige that should be theirs. The next angle was when they insisted that the entire Everitt company be taken into the Atlas deal. I refused and rather than see the affair go by the boards I offered to withdraw entirely with the financial backing I had, including Mr. McGuire, and leave the field to the Everitt people. This they refused to take up and as I would not let them into the original Church-McGuire-Flanders combination the deal whereby the Atlas plant was to have been sold last Monday fell through. Mr. Flanders and myself are no longer connected in the deal. I am making this statement in order that the inside facts in connection with the matter may become known."

Drops Names of E-M-F and Flanders

DETROIT, MICH., Aug. 3—On the first of August, the familiar names E-M-F 30 and Flanders 20 went out of existence and henceforth these two cars made by the Studebaker Corporation will be known as Studebaker 30 and Studebaker 20, respectively. This change of name has been made because the factories for these machines are now entirely controlled by the Studebakers, and the officers of the corporation as well as the dealers selling the cars felt that the change was not only advisable but virtually essential. It has been done largely through a desire for consistency and uniformity, as well as from the fact that the Studebaker name is well known and of trade value. The old monograms which the cars bore have long since lost their significance, and the concern sees no reason why the machines should not bear the name of their present makers. Not only will all cars hereafter made carry the Studebaker script name-plate, but as soon as possible all dealers will be supplied with them, so that the cars in present use may be equipped with them.

Little Demand for Crude Rubber

Crude rubber experienced another dull, draggy week with prices about stationary and both buyers and sellers inactive. Importations aggregated a rather large total, the week-end receipts being 2,800 packages. The buying was placid and was reported to be for jobbing accounts. Reports have been circulated that the Brazilian syndicate has disposed of 650 tons of hard, fine Para, about one-third of its holdings, selling in the London market. In the meantime, since July 1, the movement down the Amazon to Para is estimated at 1,600 tons. The big movement to market is probably acountable for the lack of eagerness on the part of buyers and the tremendous manufacturing consumption is said to be the main support under the market. While the bids and offers have been quietly made in practically all the markets, trade has been satisfactory. The market has stood for a week around $1.16 1-2 on a basis of up-river fine.

Overland Close Up Garford Deal

TOLEDO, O., Aug. 4—The formal taking over of the Garford Company's plant at Elyria, O., by the Willys-Overland Company occurred here on August 1, when, at a meeting of the Overland directors, John N. Willys was elected president of the Elyria company, which will be known in the future as the Garford Department of the Willys-Overland Company. At this meeting.

Market Changes for the Week

Changes in the metal market were few and far between, and whatever fluctuations took place during the week were mostly of the downward sort. Thus lead declined 17 1-2 cents per 100 pounds, tin 25 cents for the same quantity, while copper remained unchanged during the entire week. One of the interesting features of the dull copper market is that the quotation of electrolytic metal is now above that of Lake Superior copper and has remained so owing to an intense inactivity of the market. Tin was erratic and mostly weak during the last 7 days. Steel in beam and channel form found no demand, although it was offered at $1.51 per 100 pounds. The table shows the price fluctuations for the week:

Material	Wed.	Thurs.	Fri.	Sat.	Mon.	Tues.	Week's Change

A. L. Garford resigned as president of the company bearing his name, the interests which he owned in it being taken by the Willys-Overland organization. Mr. Willys' full title will be president and general manager of the Garford Department, in which capacity he has been acting for some time. The new department will be largely managed from Toledo. Mr. Willys will retain his office in that city.

Frank Briscoe Out of U. S. Motors

According to announcement made by the United States Motor Company, Frank Briscoe, one of the vice-presidents of the company, who has had charge of the designing department, has resigned. He will sail for Europe late in August to make a study of European automobile engineering. He will probably remain abroad for a year or more.

While resigning his office in the United States Motor Company, Mr. Briscoe will continue as president of the Briscoe Manufacturing Company, one of the subsidiaries of that company.

Republic Rubber Increases Capital

YOUNGSTOWN, O., Aug. 6—At the special meeting called for Monday last, the stockholders of the Republic Rubber Company voted an increase of the authorized capital from $4,000,000 to $10,000,000. A number of extensions and improvements were discussed and the semi-annual statement was read, showing a large increase in the business of the company.

At the directors' meeting following, the board declared a special stock dividend of 35 per cent. to the common stockholders of record August 1. It is stated also that an offering of preferred stock will be forthcoming in a few months. The regular cash dividend at the rate of 2 per cent. per quarter was declared.

Automobile Securities Quotations

Studebaker and General Motors were the strongest features of the week in the line of automobile securities, both companies being listed on the New York Stock Exchange and subject to the immediate effects of public demand in either direction. Reports of excellent business in the industry generally and particularly the optimistic attitude of the officers of both these companies is the cause of the strength shown. General Motors preferred moved up under active trading to 80 and both Studebaker issues advanced sharply, the common rising above 41 while the preferred rose to 97 1-2. Other issues were steady.

N. A. A. M.'s Meeting

Convenes at the Summer Home of General Manager Miles—Freight Rate Advance Discussed

Question of Car Insurance Also Considered—New Members Elected—St. Louis Dropped from Show Circuit

ONE of the most pleasant gatherings of the National Association of Automobile Manufacturers was held last week at Christmas Cove, Me., when the regular July and August sessions of the association were combined and conducted at the summer home of Samuel E. Miles, general manager of the association.

The business session, which was held on Monday, occupied about 4 hours and was largely devoted to the consideration of routine matters. One of the interesting matters that were discussed was the recently announced advance in freight rates on automobiles consigned to the Pacific coast. The former rates are $3 per 100 pounds in carload lots from Ohio, Michigan and Atlantic Seaboard common points to Pacific coast common points. The new rates differentiate between New York and New England common points, Buffalo common points and Detroit common points, and raise the rates respectively to $3.30, $3.20 and $3.10 per 100 pounds.

As the general practice is to ship two large cars or three medium-sized cars in a car, the raise would mean an advance in cost of shipment on automobiles from New York and New England of about $15 per vehicle; $10 per vehicle from Buffalo and common points and $5 per vehicle from Detroit and its common points. Just what will be done about the matter is still problematical, but the case has been referred to James S. Marvin, traffic manager of the association.

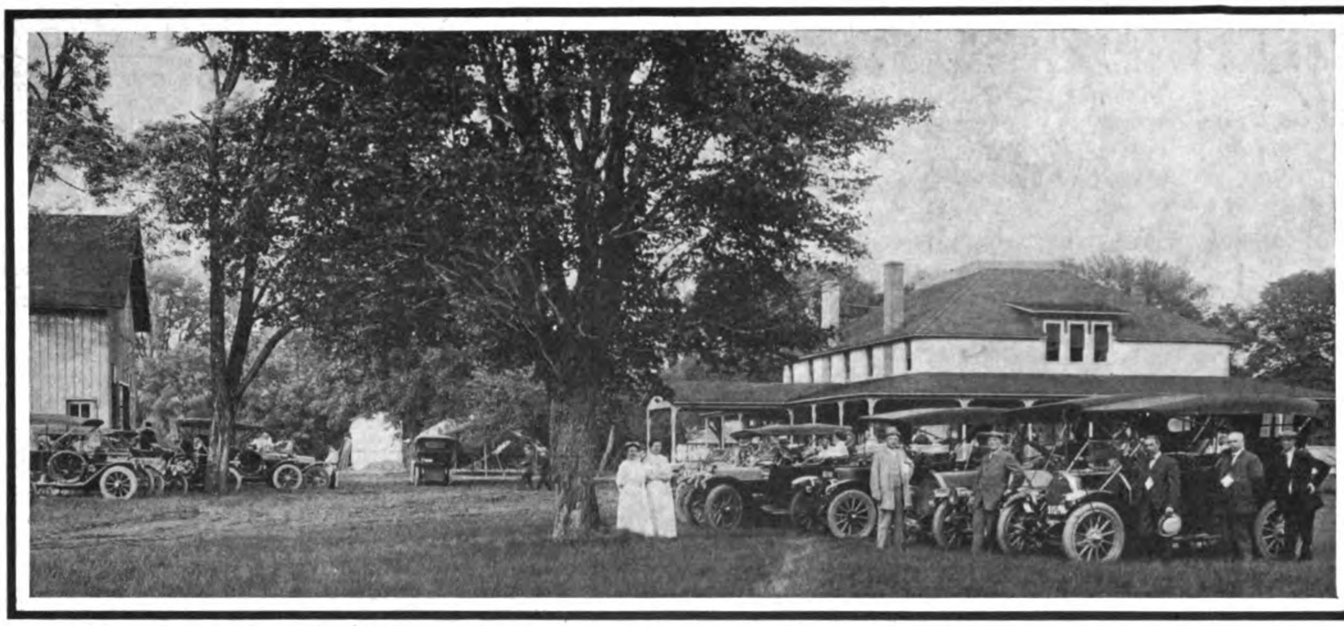
Insurance Rates Are Too High

Another subject discussed was the problem of insurance. Arguments were made that the rates charged for the various kinds of insurance were so high that many automobile owners were not taking out policies. This resulted in limiting the business of the insurance companies and the tendency was to cause owners of automobiles who were most liable to accident and mishap and who could not afford to do without insurance, to furnish a considerable part of the total business. Under these circumstances it was quite likely that the ratio of losses paid would be larger than they would be if the business was on a more reasonable basis and consequently broad and general.

No action was taken officially by the association, but the matter was referred to a committee for investigation and report.

Most of those who attended the meeting arrived at Portland on Saturday morning and were taken to Christmas Cove in automobiles. Sunday was spent in recreation as was most of Monday and all day Tuesday. Many of the visitors stayed over Wednesday and a few were still left to enjoy the hospitality of Mr. and Mrs. Miles at the end of the week.

A general meeting of the N.A.A.M. will be called for the near future, probably for the dates of the meeting at which the show allotments are made in October. The Motor Car Manufacturing Company of Indianapolis and the Warren Motor Car Company of Detroit have been elected to membership. The following changes have been made in representation: H. F. Campbell, Ideal Motor Car Company, to succeed E. C. Sourbier; Gleason Murphy, Rapid Motor Vehicle Company, to succeed J. F. Corl; H. S. Stebbins, Reliance Motor Truck Company, to succeed A. M. Bently. W. C. Teasdale represents the Ideal and Lucius E. Wilson the Warren companies. St. Louis has been dropped from the local show circuit, the dealers wishing to show in the Fall instead of on the dates suggested.



Scene at the Cold Brook Club, where the Elmira Automobile Club held its annual field day

Buffalo Club Opens New Home

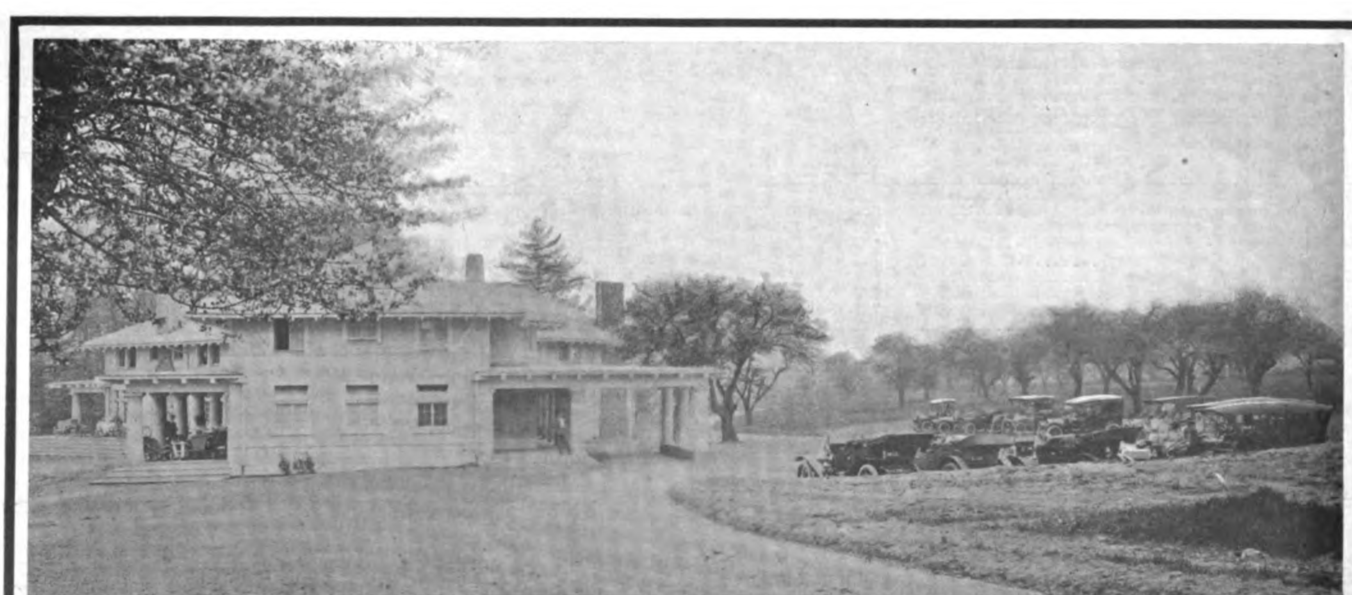
Structure Cost $75,000; Said to Be Finest of the Kind in the Country

BUFFALO, N. Y., Aug. 6—The Automobile Club of Buffalo's country clubhouse at Clarence, N. Y., which was constructed at a cost totaling $75,000, is said to be the finest country home owned by any motor organization in the United States. The estate on which this clubhouse is located comprises 70 acres, on which are stately pine and hickory trees as well as apple trees and shrubbery. The clubhouse is approached from the main highway by a broad smooth road leading directly to arched driveway. The building itself, which is 200 feet long by 136 feet at greatest width, is of Mission architecture and represents a spacious bungalow. The general reception room on the first floor has seating capacity for 500 people. This room is finished in weathered oak, unpolished, with vaulted ceilings and five fireplaces of red brick to hold large logs. Close to the main entrance in the interior of the clubhouse is a spiral staircase which leads to apartments on second floor planned especially for women guests visiting the clubhouse.

Elmirans' Annual Field Day

Over 200 Members and Friends Enjoy the Outing at Cold Brook Club Grounds

ELMIRA, N. Y., Aug. 5—About two hundred persons, including members, families and friends of the Elmira Automobile Club enjoyed the first annual field day of that organization last Wednesday at the Cold Brook club grounds, fifty automobiles being used in carrying the party to and from the grounds. During the afternoon cards and other games were enjoyed by the motorists and their guests. The menu was prepared under direction of two experienced caterers, Thomas Barnes and Frank Berner, and consisted of most delectable foodstuffs. At 9 o'clock the automobiles, which had been parked on the club grounds, were formed into a procession and the return was made to Elmira.



Magnificent country club house of the Buffalo Automobile Club at Clarence, N. Y.

Ready for the Galveston Races

Three-Day Carnival Will Bring Together Racing Cracks of North and South

GALVESTON, TEX., Aug. 3—Practice for the automobile races to be held on the hard-packed Galveston Beach, August 8, 9, 10, under the auspices of Galveston Automobile Club and the Texas State Automobile Association, has begun and daily hundreds of motor enthusiasts line the course to watch the tuning-up sprints.

A grandstand seating 10,000 people is now finished. From elevated seats in this stand the entire length of the 2 1-2-mile course will be in full view of the spectators at all times. This arrangement is new for beach races, which seldom proved spectacular because of courses being too long, permitting the cars to be seen only at the passing point. At low tide, the beach provides 200 feet of driveway, with an additional 100 feet or more which is taken up with the grandstand and parking spaces.

There are five events on the program for each of the first two days of the meet and a 200-mile free-for-all contest will be run on the third day.

Trying out a score of local cars preparatory to this week's races on Galveston Beach

Four Class C events and a special Class E event are slated for the first day, these ranging in distance from 10 to 75 miles. In the latter event, in order that a car win a prize, two or more cars must start in the same class and must finish within a period of 90 minutes. On the second day a similar event is to be run and in this the winning machine must finish within 60 minutes. Also, on the second day, three special Class E events are to be run off and several attempts will be made at the beach record.

Preparing Milwaukee's Race Course

MILWAUKEE, WIS., Aug. 6—A swarm of workmen are on the 8.2 miles of road comprising the new Vanderbilt cup course, and fourteen new culverts of the most advanced type have already been completed and the approaches graded. Two bridges are now under construction, and should be completed by August 10. The roads are all of macadam and have been down for more than 15 years. The surface is being scarified and a layer of 4 inches of No. 2 rock is being added. Two inches of fine screenings will complete the surface, which after being treated with a 70 per cent. asphaltum preparation as a binder, will be rolled to granite-like surface and later oiled and sanded several times. The 2.5 miles of concrete road which will comprise part of the course will be ready at the same time as the rest of the work.

Dawson Refused Reinstatement

Contest Board Also Disqualifies Schacht Company for Violating Advertising Rule

FOR violating rule 75, which prohibits advertising as performances of stock cars the showings of automobiles in races under non-stock conditions, the Schacht Motor Car Company, of Cincinnati, has been disqualified and suspended until the first of the year.

The offense upon which the ruling is based was the performance of the Schacht entry at the Memorial Day race at Indianapolis.

In addition to the Schacht matter the Contest Board of the American Automobile Association considered a number of other cases. Applications for reinstatement by Joseph C. Dawson and C. E. Shuart, suspended for participating in an unsanctioned meet, were held up pending a more satisfactory explanation. Joseph M. Matson was restored to good standing, having been suspended for failure to report at a sanctioned meeting in which he was entered. Hugh B. Andrews, promoter of the recent race meeting at West Side Park, Wilkes-Barre, Pa., was suspended until the first of the year for failure to comply with the requirements of the board with regard to safety precautions.

The following official records were accepted:

Santa Monica Road Race, Los Angeles, Cal.

Race	Miles	Car and driver	Time
Free-for-all Non-Stock	303.012	Fiat (Tetzlaff)	3:50:57.

ST. LOUIS, MO., Aug. 4—The annual run of the Automobile Manufacturers' and Dealers' Association of St. Louis is to be a sociability event instead of a reliability. Owners will be invited to join the tour, which will be run off August 22, 23, and 24.

Right or Left Control?

Engineers and Lay Readers Take Up Discussion of "The Automobile's" Article on Subject

Advocates of Left-Side Steer Offer Excellent Arguments in Favor of Their Position

DES MOINES, IA.—My opinion is that the left-side drive is the proper one, after having used a car for one season with a left drive and previously using one with a right-side drive. I believe the advantages of the left-side are very clear, especially for city use. In passing a team going in your direction on the country road you are more apt to watch the road closely with a left-side drive than with the right and in this case you can always better be your own judge as to how far to turn out, and in meeting a team coming in the opposite direction, or in meeting another car, you can stay to the center of the road and allow for less room between the cars or between the team and car if the road is narrow.

If you are following a street car in the city it is certainly an advantage to drive behind a car where there is a double track and be able to get out far enough to see if there is a car coming and avoid same if it is coming, which is impossible if you have a right-side drive. Also if you are driving where you have to turn square corners it is easier to see the man coming behind who would likely be driving faster than you and passing you to your left.

I note that a great many people having right-side drives have a tendency to stay very close to the center of the road when you are meeting them. Sometimes this makes it dangerous to pass on a narrow highway.

Personally I have no choice so far as lever control is concerned, either right or left-side is satisfactory, and after selling both right and left-side drives for 2 seasons I find that there are a great many people not favorable to the left-side drive until after they have had a little experience, after which they always seem to favor it. For city use I would certainly recommend the left-side drive, and for country use I think one will answer the purpose as well as the other.—F. S. DUESENBERG, Sears Automobile Company.

Horsemen Favor Left-Side Seat

DETROIT, MICH.—The subject of left-side steering is one on which I have had fixed ideas ever since I built my first cars in 1900 and 1901. As every car is used a great deal in towns or cities I do not believe the possible advantages of a right-side drive for open country touring need to be taken into consideration. I have driven both kinds a great deal and I believe the preponderance of advantages is in favor of the left-side type.

In crowded traffic I believe a left-side steered car will make at least 25 per cent. better time than the right side. The ability to see if the road is clear to the left for passing enables one to keep going on take advantage of every opportunity to pass.

In turning to the right one can look to the gear as easily from the left side as from the right, and in turning to the left to cross the counter running traffic the left-side seat is obviously the better position. The same holds true also when turning around to go in the opposite direction. When riding on the front seat with the driver of a right-side steering car one is often asked by the driver whether or not the road is clear to the left of the overtaken vehicle.

Several years ago there were a number of articles in *Rider and Driver* on this subject and they disclosed the fact that many expert horsemen favored and were driving in the left-side seat. If right-side steering is accepted in left-turning countries such as England and others, and as has recently been adopted in France, it seems only logical that left-side steering is correct for right-turning countries like America. I have yet to see a communication in any of the English papers objecting to right-side steering. This considering the Englishman's habit of writing letters to his favorite paper upon the slightest provocation, would seem to be the best indorsement of left-side steering in this country.

As to country road driving I believe that it is more a matter of what one is accustomed to rather than a question of the relative advantage. England has notoriously narrow and hedge-obstructed roads but we hear no demand for left-side steered cars for country use. Personally I prefer the left-side steering car for all uses after driving both over long periods of time and under all conditions. I believe the left-side control has retarded the adoption of left steering but with the advent of the center control I expect to see left-side steering come rapidly into favor for both pleasure and commercial cars.—EDWARD T. BIRDSALL, M. E., Consulting Engineer.

Engineer Shows Left-Side Merits

DETROIT, MICH.—I think the problem of whether the right or left-side drive is preferable can be divided into two classes: matters regarding the mechanical construction and, second, advantages to driver and passengers.

Now as regards the mechanical construction of the car, the left-side drive results in having the change-speed levers mounted directly on the gearbox, forming one unit, with consequent elimination of the usual right-side drive troubles where two telescoping shafts run from the gearbox to frame, on the end of which the control levers are mounted. This construction requires very careful fitting to avoid too much rattle on the one hand, or cramping on the change-speed lever on the other, due to the fact that each connects two different members of the chassis—namely—the frame and the gearbox, and these two units are not immovably connected to each other. This point, of course, assumes the placing of the change-speed levers in the center of the car. This construction, generally known as central control logically follows left-side steer, owing to the fact that with the fore-door bodies levers on the left side are very awkward to install properly in a reasonable width of body.

Most makers have found it necessary in the past to use heavier springs on the right side of cars with right-side steer, due to the fact that the torque reaction of the motor causes a considerable load on the right side of the car, and with well crowned roads there is also a tendency for a greater weight to be thrown on the right side. The tires carried on the right side also tend to increase the weight, and with right-side drive the driver also sits on that side. With left-side drive the driver's weight is thrown on the left side, and when there is no other passenger in the car (and considerable driving is done alone) his weight balances to a certain extent some of the other constant weights on right side of the car.

Then such a small item as the position of the iron for supporting top front bow is bettered with left-side drive and central control, owing to the fact that this arm can be placed further forward without interfering with driver's elbow when changing gears and putting on brakes. Anyone who has had his funny bone shocked severely due to contact with the top iron in putting on brakes and changing gears suddenly will not fail to appreciate this point.

The advantages of the driver are many. Also to the passenger in the front seat. The obvious ones, of course, which have been most noticed, are the easy exits of passenger and driver to the sidewalk or curb without having to walk around the front of car through the mud. Also the passenger can step directly from the running board to the curb without the considerable jump from the running board to the street, which is a very important item in the case of elderly people and invalids, and with such people the front seat is a great favorite, on account of its being more easy riding and easier to enter, due to the being right alongside door.

Another advantage of left-side drive is the ability of the driver to see around street cars and slow-moving vehicles it is desired to pass. With left-side drive the driver can see an approaching street car or vehicle beyond the car he wishes to pass, before turning way out. With right-side drive it would be necessary to clear the car ahead before the driver could see whether another car or vehicle was approaching. This is especially important in winter time when in many parts of the city, after a heavy snow storm, the traffic is confined principally to the two central car tracks. Also the mirror used for observing traffic in the rear is of much more value with driver on the left side than where he has to see the mirror from a considerable distance or from the right-hand side of the car.—J. G. PERRIN, Lozier Motor Company.

Right Drive and Left Control

EAST CANAAN, CONN.—Your recent articles on the merits of right and left-side control were worthy of the attention of all motorists, but there is one point in this controversy that I failed to see mentioned. Personally I favor right-side steer with central levers for this reason: When shifting gears it is possible to steer and at the same time throttle the motor with the right hand, leaving the left free to work the shifting lever. Now with the levers at the right of the driver, in order to shift gears, it is necessary for him to remove his right hand from the throttle lever and also the wheel, which is rather awkward for anyone who throttles by hand.

Of course this does not apply to those who use the foot accelerator, but in my humble opinion, the foot accelerator is all wrong, the foot not being as sensitive or as well adapted to this purpose as the hand. It is very hard also to properly control a car on a rough road with the foot.

It is very gratifying to me to see the rapid gains that are being made by the little-six type of car. The superiority of the six-cylinder motor seems to be generally admitted, but the makers of this style of engine have usually built heavy, high-powered cars and charged as high a price for them as they thought the luxury-loving class could be induced to pay.

I believe that there is a fast increasing number of the motor wise who are waiting for a reliable, low-powered moderate priced $1,500 to $2,500 light six, and I predict a brilliant future for this type of car.—D. C. CANFIELD.

Left Drive Favors Passengers

NEW YORK CITY—The point of left or right-side control is very vital to say the least. I cannot see any advantages of the right-side control. Center placing of gear shift is coming fast and the public demands a right-hand operation. This forces the steering column to the left. In road driving I have always feared the oncoming car above everything else for this reason. Two cars meeting at high speed pass each other at the sum of the two speeds. With a ditch on one side and the oncoming car on the other I would much prefer to just miss the oncoming car and take the chances on the ditch.

In overtaking another car traveling in the same direction you do not attain the high speed of passing and usually take more precaution to see that you have a clear road to get around or probably because you don't know which way the fellow in front will turn.

The fore-door has come to stay and for the sake of alighting on the sidewalks or stepping stone it is certainly preferable to have the steering column on the left side. The passengers in my opinion should have the preference over the chauffeur.—ANONYMOUS.

NEW ORLEANS, Aug. 6—Passengers arriving on last week's boat from Bermuda state that the question of lifting the ban against automobiles is being considered. Motor cars have been prohibited on the island for several years due to recklessness that characterized their operation when first introduced into Bermuda.

Foreign Trade Openings

Opportunities Abroad as Indicated by the Government Daily Reports from Consular Stations

2-, 3-, 5- and 10-Ton Trucks in Demand—Agencies for Pleasure Cars Wanted in European City

AUTOMOBILE TRUCKS—A leading dealer in automobiles and accessories in a European city informs an American consulate that he desires to receive from American manufacturers of automobile trucks immediate offers f.o.b. New York of automobile trucks of 2 to 3 tons capacity. Prices in excess of $2,500 cannot be considered, nor offers which do not carry with them exclusive agency rights for the country. Correspondence should be in English, and catalogues and drawings should be accompanied by all necessary technical information. File No. 9270.

MOTOR TRUCKS FOR HAULING ORE—A report from an American consul in Mexico states that a company in his district is in the market for a couple of motor trucks for hauling ore from mines to the railways. These trucks would probably require steel instead of rubber tires, as the roads on which they are to operate are rough, rocky, mountain stretches. They would have to be sufficiently powerful to travel short distances of 20 per cent. grade road. In the absence of rubber tires the trucks would have to be equipped with pneumatic shock-absorbing springs in order to preserve the motor. Information and prices are requested on 3, 5 and 10-ton ore capacity trucks. File No. 9262.

Want Passenger and Freight Cars

AUTOMOBILE AGENCY—An American consul in a European country reports two reliable business men in his district, one of whom resided for 12 years in the United States, desires to procure the agency of a strongly built, medium-weight, good appearing automobile which can be retailed there at from $900 to $1,860. The inquirers are well acquainted with the business element of the city in which they are located, speak and write English, are energetic, and in the opinion of the consul would make first-class representatives for any automobile firms desiring representation. File No. 9261.

PASSENGER AND FREIGHT AUTOMOBILES—One of the commercial agents of the Department of Commerce and Labor reports that a bank in an American city, with European connections, is requested by a prominent foreign automobile transport company to procure catalogues and price lists of American passenger and freight automobiles. All communications should be transmitted to the American offices to be forwarded. File No. 9301.

DIESEL ENGINES—An American consular officer reports that a firm in his district desires to secure the agency for American manufacturers of Diesel engines. It is believed these goods can be introduced to the satisfaction of the manufacturers. The members of this firm, one of whom is an American, are energetic and have an excellent reputation in the city in question, as they have been identified with leading local concerns. Correspondence may be in English. File No. 9295.

TRADE WITH BARCELONA—At the request of the consulate general, the Barcelona custom house compiled statistics showing the imports into Barcelona from the United States. These indicate increasing possibilities for the introduction of American goods. For instance, seven more automobiles were imported from the United States in 1911 than in 1910, but there is undoubtedly opportunity for a far greater trade here if the proper methods are adopted by the American manufacturers.

TRADE WITH VANCOUVER—The automobiles invoiced at the Vancouver consulate general for shipment to the United States during 1911 were valued at $36,397, an increase of $7,919 as compared with 1910.

Exports Gain 65 Per Cent.

Foreign Countries Get Over $10.000,000 More of Our Automobile Products Than Last Year

Imports Increase Only 8 Per Cent. for the Fiscal Year—Tire Exports Show 27 Per Cent. Gain

WASHINGTON, D. C., Aug. 5—Official figures of automobile exports and imports for the fiscal year ending June 30, 1912, have been issued by the Department of Commerce and Labor. The showing, as far as export business is concerned, is not up to the estimates sent out from semi-official sources last month, but it is sufficiently impressive in that it proves that the export business was about 65 per cent. larger than it was during the foregoing period based upon the official figures. Last year, it will be remembered, the manufacturers who had been particularly active in the export field, protested that the government figures were much too low and the same kind of a protest is being heard now, although so far it has not been so pointed as it was last year.

The total amount of export business in the automobile line, including cars, parts and tires was $25,657,294, against $15,509.229, during the preceding fiscal year.

The tabulation and comparison are shown in Table I.

It will be noted that Canada maintains first place as a customer of the United States and that Great Britain and British Oceania follow in order, the three British divisions taking an amount in excess of the total exportation of the previous year.

There was a slight reduction noted in France, Germany, Italy, Mexico, and the West Indies and a measurable increase in South America and in scattering business.

With the value of tires reckoned in with the totals to aggregate sum of the exports would probably reach the unofficial figure of $28,000,000.

The automobile imports for the year show a total of $2,438,325, which is an increase of $288,000 over the business of the previous year and a decrease of $1,400,000 as compared with the fiscal year of 1910.

The figures and comparisons are shown in Table II.

Tire Exports Gain 27 Per Cent.

WASHINGTON, D. C., Aug. 3—Exports of motor car tires during the fiscal year ended June 30, 1912, amounted in value to $2,657,809, as against $2,085,107 worth exported during the previous fiscal year. The exports for the month of June increased in value from $246,625, in 1911, to $321,889 in 1912.

The total imports of India rubber during the fiscal year just ended amount to 110,210,173 pounds, valued at $93,013,255, as against 72,046,260 pounds, valued at $76,244,603, imported during the fiscal year 1911.

The imports for June last amounted to 6,815,153 pounds, valued at $5,442,859, while in June a year ago the imports amounted to 6,322,768 pounds, valued at $5,508,081.

Water and Oxygen the Enemies of Aluminum—Centrifugal Oiling of Four Crank-pins—Radius Rods as Base for Chain Casings—Some Errors in Laboratory Tests—A Revision of Horsepower Formulas with Stroke Considered

CORROSION of Aluminum—Through an extended series of experiments at the Royal Prussian Station for the Testing of Materials some of the conditions have been determined which lead to a decomposition of aluminum. It had been observed that kitchen utensils made of this material in very numerous instances deteriorated rapidly even before they were taken into use, as when stored in the warehouses of manufacturers, but especially when they were used for cooking purposes. Such utensils are usually stamped cold from rolled plates or sheets. The efflorescences, scale formations and marks of decomposition are in some instances irregular or evenly distributed over the entire surface, but in many other instances run in streaks following the direction in which the metal has passed through the rollers. In some cases raised blisters covered efflorescences of the metal underneath. A chemical examination tended to show that the silicon content of the metal has nothing to do with the decomposition. Long exposure to the atmosphere, on the roof of the test station, and to changes of temperature, but with the exclusion of direct contact with water or snow, showed conclusively that the metal did not undergo any changes in appearance or weight under those conditions. On the other hand, constant exposure to the municipal water on tap at the institution showed very strong effects, and these were mainly local blisters and scales. The local attack was most pronounced with the hardest metal; that is, the metal which had been rolled under highest pressure and had received the smoothest finish. But the loss of weight was in those cases least pronounced. Tests with distilled water gave a larger total loss of weight, but the attack was never local, consisting mainly in transforming a film of the entire surface into hydroxide of aluminum.

The various forms of decomposition caused by the exposure to the municipal water were very similar to those observed on the used cooking utensils which had been sent in from various sources for test purposes. Tests consisting in exposure to air alternating with exposure to municipal water showed attacks which were mainly local like those resulting from constant exposure to the water alone, but they were less pronounced.

Further tests at which aluminum plates were submerged for 62 days in distilled water to which the oxygen of the air had no access, watergas being blown over the vessel for the entire duration of the test, showed no effects; and the municipal water under the same condition also failed to attack the metal. This demonstrated that the combined presence of water and oxygen is required to effect any decomposition, as in the case of iron, and also that the aluminum at house temperatures has no power to decompose the water. A special series of comparative trials proved that higher temperatures of the water and the presence of free carbonic acid gas, especially the latter, aggravated the decomposition of aluminum very much.—From *Werkstattstechnik*, July 15.

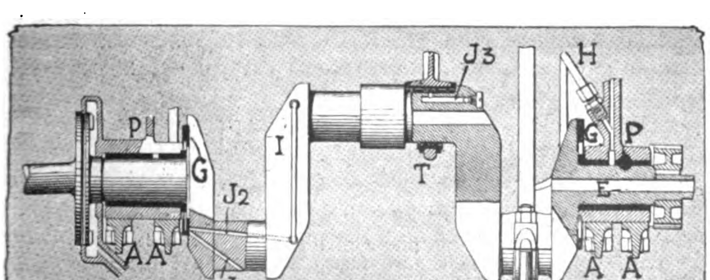

Fig. 1—Centrifugal oiling system for Delahaye 4-cylinder crankshaft

Delahaye Oiling System—The general plan of Delahaye cars is a model of conservatism, showing a typical shaft-driven car with a four-cylinder motor and the change-gear in the middle of the chassis. The 1912 date crops out in some of the details. The cylinders have a bore of 85 millimeters (3 2-5 inches) and a stroke of 130 millimeters (5 1-5 inches). The maximum torque is developed at 1400 revolutions. The monobloc motor casting encloses all cylinders and all the manifold piping for cooling water, gas intake and exhaust, which arrangement gives a clean-cut appearance and silence. The crankshaft is supported only in two bearings P, Fig. 1, but is short and thick and hollow. Its central bore E admits of increased diameter and rigidity with minimum weight and also serves as an air vent from the crankcase, relieving possible accumulations of air pressure therein, and has the advantage over the customary air risers that the air thrown out through this bore comes from the axial line of the mechanism where there is no oil mixed with the air, since oil is thrown to the circumference by centrifugation. The result is that the outside of the motor and the crankcase remain free from oily deposit. A little weight saving in the movable parts is effected by having the connecting-rod knuckle of the width of the crankpin only on the pressure side, where the force of explosions is taken up, while the semi-circular yoke T, which only takes care of compression and momentum, is considerably narrower, as shown in Fig. 1. The two end bearings of the motor shaft are supported by long bolts AAAA, which connect them direct with the flange of the motor casting, relieving the aluminum crankcase of working strains.

THE OILING OF THE CRANKPINS

Oil is sent from the bottom of the crankcase to the two end bearings of the shaft by means of a gear pump and the oil leads H. From each of these bearings it must then be sent to two of the crankpins, and this is done as follows; The oil which gets to the outside of the bearing bushing under pressure is gathered in an eccentric ring oiler or gutter G by centrifugal action, the gutter being attached to the outside of the crankarm, and at the point farthest from the shaft axis two holes are bored in the gutter registering with conduits J1, J2, bored in the crankarm and crankpin. One of these conduits takes the oil to the middle of the surface of the first crankpin, the other goes through to

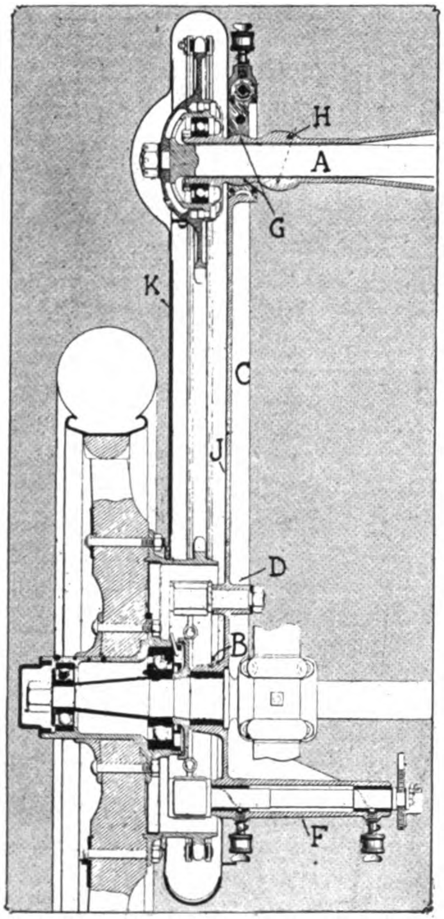

Fig. 2—Chain case and parts on which it is mounted, shown in section

the second crankarm, and is continued by an exterior tube I, which is bent in a curve and takes the oil to a conduit in the second crankpin—this conduit being similar to the conduit J3 shown in section in the third crankpin, which is reached with oil from the bearing at the other end of the crankshaft by exactly the same method. These canalizations are all laid out so as to lead steadily away from the axis of the construction to secure centrifugal action at all points. So that the short conduits to the crankpins nearest to the shaft bearings shall not rob the other conduits of their oil feed a little radial partition is placed at the most eccentric point in the ring oiler between the two holes from which the oil is taken, and when the oil is thrown out against the ring from the shaft bearing it gathers equally on both sides of this partition, assuring the same quantity of oil for each of the two conduits.

The overflow of oil from the crankpins which is scattered centrifugally in the crank case serves for the lubrication of the camshaft, the cylinders and the pistons. The latter carry a piston ring near their lower ends to obviate excessive cylinder oiling.—From *La Vie Automobile*, July 20.

—

Charron's Chain Case Construction—The requirements of a chain casing are that it shall be dust, oil and water-tight, shall not interfere with the adjustment of chain tension, shall be substantially attached and neither vibrate or rattle, shall allow easy access to the chain for lubrication or replacement and shall accommodate itself to all the displacements to which the rear axle is subject without resisting them, suffering from them or ceasing at any moment from functioning as a protector of the chain. It is generally believed to have been shown by experience that in order to do all these things lastingly it must be rigid in itself but not quite rigidly mounted; also that it cannot be successfully made as an accessory adaptable to different constructions but must be designed especially for each type of car.

The design shown in Figs. 2 and 3 refers to such a special construction intended for Charron cars. The casing is mounted upon the radius rod, and this, which is of course also the chain adjuster, is of the special design illustrated in Fig. 3. Upon this departure from earlier methods the general interest in the construction principally depends. The radius rod C is pressed from sheet steel and is of flattened U-section. The large annular flange B near its rear end, which is lined with a bronze bushing, is journaled upon a bearing surface formed for this purpose upon the rear axle. The front end is formed as one-half of a collar, to which the corresponding other half is bolted when the mechanism is assembled. At the two sides of the rear-axle flange are smaller flanged apertures, D and F, one holding the pin upon which the brake shoes are pivoted and the other constituting a long bearing for the shaft by which the brake cam is forced against the free ends of the shoes. The four arms of the radius rod serve for the permanent attachment of a flat piece of sheet steel J, which forms the back of the chain case.

The collar at the front end of the radius rod clasps an eccentric disk which is formed of two halves pinned together upon the stationary tubular housing of the jackshaft A, the bore in the disk being concaved to fit a ball-shaped bearing G on this housing. A larger ball formation H on the same housing where it passes through the frame reach admits of some compensating action between the jackshaft and the vehicle frame when the latter is twisted. The middle portion of the circumference of the eccentric disk is cut with helical gear teeth with which meshes a worm mounted vertically in the collar of the radius rod and ending in a squared key, so that it may be turned with a spanner. A grease cup sends lubricant to this chain-adjustment gear by which the rear axle may be pushed back to make up for lengthening of the chain and which thus presupposes shackled suspension of the rear springs at both ends. The socket joint at the front end of the radius rod is, of course, intended to permit those misalignments which follow with the action of the vehicle springs when one of the rear wheels is raised higher from the ground than the other and to do this without setting up torsional strains in the radius rod or the chain case attached to it.

The flat plate J which is riveted to the radius rod has a narrow flange at the top and bottom and around its circular rear edge, and to this flange the main and rear part of the chain casing is secured by screws. It is made of thin sheet steel in two halves, which overlap along the dividing central line, and the fit around the brake drum is safeguarded by a packing ring. This portion is not intended to be removed unless the wheel is taken off, as all adjustments and the lubrication, as well as repairs of chain links, take place at the front part, which is separate and removable without effort. It extends from the middle vertical line through the collar with the eccentric, so far to the front that it can always be in the same position irrespective of the chain adjustment. The opening at which the chaincase is passed over the front chain pinion is completely covered at the back by the collar and the eccentric, and the back plate of the front portion of the casing fits up against this collar, while its curved-over edge can be sprung into the similarly curved-over edge of the main portion. A semi-circular cut-out in its face plate in conjunction with a similar semi-circular cut-out at the front edge of the main portion of the casing constitutes a circular opening corresponding to the location of the chain pinion, but this opening is covered with a saucer-shaped hood which at one-half of its circumference is riveted to the face plate of the detachable front portion of the casing—allowing the convex spider of the chain pinion to project into its curvature—while its rear edge is free and is passed under the edge of the semi-circular cut-out in the face plate of the main portion of the casing, against which it fits snugly. Above and below this bell-shaped cap, two clips secure the front face plate of the front portion of the casing to the face plate of the main portion. When access should be had to the chain for any purpose, these clips are unfastened and the whole front is drawn forward together with the cap. In this manner even the replacement of the chain pinion may be effected without dismounting the chain casing or removing any other part than the front lid, as it might be termed.—From *La Vie Automobile*, July 13.

—

New Power Formulas—Owing to the general adoption of a lengthened stroke in French automobile motors and to the general advancement in design by which the efficiency of motors has been greatly increased, especially at high motor speeds, the need of new formulas for calculating motor power has been felt by the French government, with a view to establishing a scale for the taxation of automobiles somewhat in accordance with the power actually at disposal in the various vehicles, and for the purpose of arriving at such suitable formulas the co-operation of the technical committee of the Automobile Club of France was invited. This committee gathered data from the manufacturers relating to 95 different motors intended for pleasure automobiles, including 74 4-cylinder, 11 2-cylinder, 4 1-cylinder, 5 6-cylinder and 1 8-cylinder motors, besides 14 motor truck motors. In these data measurements of bore (D) and stroke (L) in millimeters are supplemented by test figures representing the horsepower (P) at a given number of revolutions per minute (w), to which corresponds in each case a certain linear piston speed (v) given in meters per second, and a mean effective pressure (p) which is calculated in kilograms per square centimeter. All the figures applied to motors of 1911 manufacture, and they were found to represent so many variations in design and working results that a division into four classes was called for. The division was made according to the linear piston speed of which the mean effective pressure is normally a function, and these factors, v and p, are therefore not represented in the formulas themselves. A division according to cylinder volume had first been found to result in the need of too many classes. The classes proposed were (1) ordinary automobile motors with piston speeds up to 6 meters, (2) automobile motors with a piston speed above 6 meters, (3) truck motors in which the mean piston pressure averages 5.8 kilograms, and (4) aviation motors in which the piston pressure is abnormally high.

By comparison of the dimensions and other figures given for the motors in each of these classes with the test figures relating to angular speed and horsepower which the manufacturers had guaranteed to be correct, the committee evolved four formulas rating the motors according to bore, stroke and angular speed and differing only in the numerical coefficient. Denoting the number of cylinders by n, the horsepower rating is obtained by multiplying $\frac{D^2Lw}{10^8}$ with $\frac{n}{2}$ for class 1, with $\frac{n}{2.9}$ for motors of class 2, with $\frac{n}{1.8}$ for class 3 and with $\frac{n}{1.6}$ for class 4.

These formulas were submitted to the government committee under the ministry of public works with the expectation that this body would endeavor to unify them into a single formula for taxation purposes.—From *Bulletin Officiel*, June.

—

Errors in Motor Testing—The apparatuses used for measuring the power of a motor are nearly always either the (1) Prony brake machine or (2) the Renard mill. In the case of the test by brake one reads off the torque and the number of revolutions per minute and deducts the horsepower from the formula

$$P = 0.0014 \text{ w.f}$$

in which f is the number of kilograms placed on the end of a scale beam 1 meter in length and w is the number of revolutions.

With the Renard mill the motor power is measured by the resistance of the atmosphere to the rotation of the bar and the planes it carries, and the formula

$$P = aC\left(\frac{w}{1000}\right)^3$$

in which C is a constant determined by the position of the planes upon the bar and a is the weight of a cubic meter of atmosphere at the moment of the test. To simplify matters, tables have been compiled giving values for P at any number of revolutions for a barometric pressure of 760 millimeters and for a temperature of 10 degrees C., and, if the barometer and the temperature differ from these figures, corrections corresponding to the differences are read out of another table and are applied. The result is taken as an exact expression of the motor power.

If, however, a comparison is made between the figures obtained by these two methods of measuring, or even if a comparison is made between two tests made by the same method on two different days, or at two different hours of one day, the figures usually disagree, and it is customary to say that the motor power varies.

Nothing could be more erroneous. It is admitted and seems indisputable that, for the same motor and other things being equal, the power must be proportionate to the weight of the explosive mixture in the cylinders; in other words, to its density. And, in fact, it has been demonstrated by the systematic experiments of Sainturat that a motor loses 16 per cent. of its power when taken from sea level to an altitude of 1,000 meters, which means a difference of 90 millimeters in barometric pressure, the influence of temperature being ignored. When the power of an explosion motor is stated there should therefore be added: With a barometric pressure of 760 mm. and the thermometer at, say, 10 degrees C.

But in the case of brake tests no account is taken of these factors at all, with the result that two tests, of which one is made in the summer with the barometer at 735 and at a temperature of 45 (which is not rare in a testing room in summer) and the other outdoors in winter with the barometer at 780 and the thermometer at 5, vary widely.

When a Renard mill is used the results are still worse, for it is the invariable custom to correct the reading according to the barometric and the temperature conditions, and, in doing this, one falsifies doubly the final figure instead of correcting it. In reality it is the first reading which is substantially right, as will be perceived from the following:

With this style of brake which acts against the air, the torque and consequently the motor power is, other things equal, proportionate to the density of the air in the laboratory, since the resistance to the rotation of the planes grows with this density. But the weight of a cylinderful of explosive mixture is also proportionate to this density and grows with it. The correction relative to the state of the barometer and to that of the thermometer consequently makes itself automatically, and when the reference table has been established for a barometric pressure of 760 and a temperature of 10, by means of a dynamometric scale, the first reading from the table gives under all circumstances the power of the tested motor as it would be for the conditions expressed in these figures, provided of course the motor is an internal combustion motor.

It may not be strictly accurate that the power of the motor grows with the density of the explosive charge and that the variation in the latter compensates with exactness for variations in the density of the outside air which is beaten by the planes of the testing apparatus, but the error, if any, falls within the tolerance allowed for experiments, and in practice it may be said that:

(1) The gross reading given by a Renard apparatus gives without correction the true figure for the power of an explosion motor for certain atmospheric conditions accepted as standard, and

(2) The gross result given by a Prony brake test should be corrected according to the conditions of the atmosphere before it can represent the power of a motor under the conditions accepted as standard.

In other words, one should do exactly the opposite of what is customarily done. Then the final results will be found to bear comparison, as the author has found by practical tests.—A. Colmant in *La Vie Automobile*, July 20.

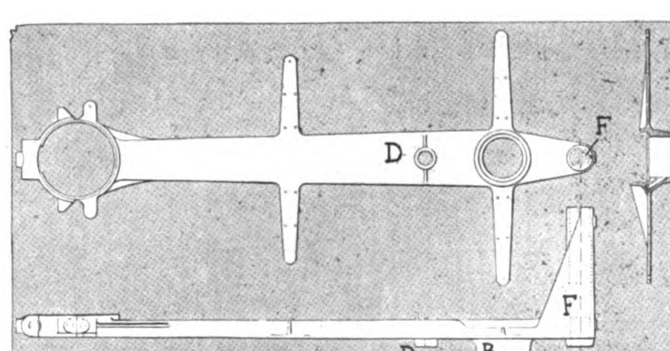

Fig. 3—Radius rod designed as foundation for Charron's chain case

The Warning Signal: Its Care and Repair

Importance of Maintaining Efficiency—How to Keep Motor-Driven, Vibrator and Exhaust Horns in Condition

Diagnosing the Troubles Peculiar to Each Type, and How to Apply the Proper Remedies

A TRIP through the testing and repair department of a manufacturer of warning signals would teach any automobilist a lesson of lasting value. If he could stand at the elbow of the factory expert and watch him at work with no tools but a screw driver and a small brush putting into perfect condition within five minutes' time horns which have been sent back to the factory as useless by car owners his eyes would begin to open. If he could see the letters of condemnation on perfect electric horns which would not operate because the batteries were run down and the owner did not know the seat of the trouble he would be still more surprised, and yet this and many parallel cases are the experience of all the large warning signal makers.

The study of the care of warning signals other than the bulb horn may be divided into three classes: the electric motor-driven horn, the vibrator horn and the exhaust type. The first consists of a motor with rotating parts, the second works on the well-known buzzer principle and the third are whistles of different styles which are blown by permitting the exhaust gases to pass through the proper channels.

In studying the repairs on each type of horn a representative make will be taken and fully described in detail and where radical differences are noted in other horns they will be mentioned.

Klaxon Troubles and Their Cures

More than 75 per cent. of the Klaxon horns returned to the factory for repairs have been damaged because the owners have neglected to attend to their lubrication. Short circuits claim the next largest share, about 20 per cent. of the total, while 5 per cent of the repairs are miscellaneous.

Once every month the bottom plate should be removed and the commutator surface cleaned with a small brush dipped in gasoline. A light film of vaseline or non-fluid oil is then applied to the commutator. The results of the neglect of lubrication are a decided falling off in the volume of sound which will take place in the early stages. After a month's use a black carbon deposit frequently gathers on the commutator surface and can be removed as stated. After a short time the carbon brushes become glazed and the motor will not run satisfactorily.

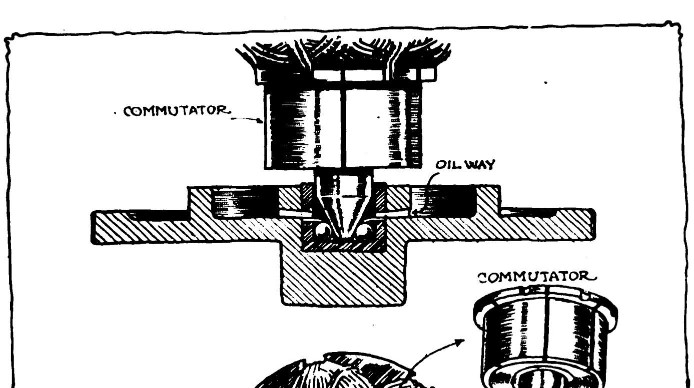

Fig. 1—Parts of Klaxon requiring owner's attention

When any trouble develops with a Klaxon the first thing to do is to remove the bottom plate and see if the commutator is dry. If so, the treatment with gasoline and vaseline will restore it if improper lubrication is the only trouble.

Short circuits in the Klaxon can be roughly divided into two classes: those in which the current passes to the horn casing and those in which the short circuit is in the commutator. If the bottom plate is removed and it is noted that the commutator is sufficiently lubricated and has not become dirty, the probabilities are that there is a short circuit. This can be found by first connecting one of the wires to a binding post and then touching the other along the casing. If a spark is noted it signifies that there is a short circuit to the casing. If there is no spark the other binding post may be tried with the casing grounded. When a spark is detected at either of the binding posts with the casing grounded the trouble will be found in a leaky insulation at the point where the binding post giving the spark passes through the casing. The washer at this point will have to be renewed unless the interior wire be disconnected, in which case the connection will have to be remade.

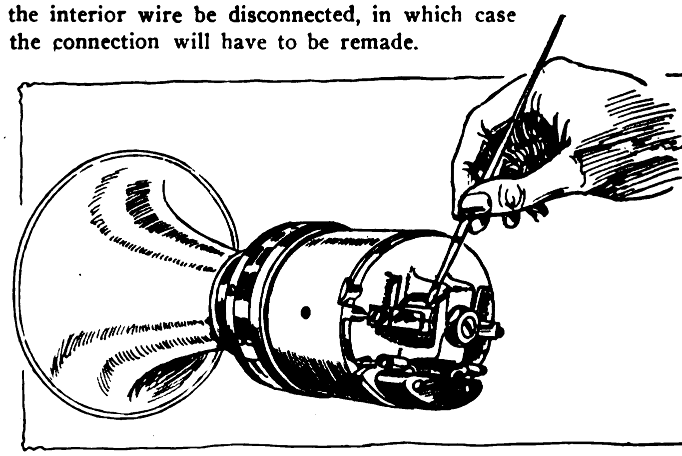

Fig. 2—A drop of oil here helps the Sireno

If the short circuit is not found in the casing, there may be one in the commutator. This can be found by slipping pieces of paper between the brushes and the commutator, grounding the casing with one wire and then trying for sparks with the other on the commutator. This is a matter of factory repair.

Motor-Driven Horns Require Oil

Several horns have been returned, where the owners have permitted the motor to run dry or have failed to operate owing to too tight an adjustment so that the motor was stalled and the owners have then tried them on a current of high voltage. In several instances a 210-volt lighting circuit has been put through the instrument and as a result the whole armature winding blown to pieces. Repairs for the burning out of the motor owing to the use of too high a voltage must be done at the factory. Many Klaxons are in use with the adjustment on the rotor too tight. This consumes much unnecessary power and at the same time cuts down on the sound efficiency. The rotor shaft passes through an eccentric bushing which, when turned around, controls the distance between the toothed wheel and the diaphragm anvil. When the wheel is too close to the diaphragm the latter is bent back, thereby reducing materially the distance through which it can vibrate in the first place and secondly opposing a resistance to the motor which may be so severe that it will stall. A stiff sound that cannot be mistaken when heard will appraise the vigilant automobilist that the adjustment is too tight. The correct note of the Klaxon involves what the makers call a tiger after the main note. It is a dying-away sound that is familiar to all those who have heard this signal. When the adjustment is too tight this "tiger" disappears. To make the correct adjustment if the sound is noticeably loose or tight, loosen the hexagonal lock-nut, located between the top of the motor and the diaphragm casing, by turning from right to left. Start the current rotating the motor until no sound is heard. Start at this point and turn the motor back slowly in either direction until the note is loud and clear. Set the lock nut, turning up tightly and being careful not to alter the adjustments just made. The note should be clear with a distinct "tiger."

It will occasionally happen that a very ragged sound will be given by the Klaxon. Unless it were known where to look for this trouble a novice might search a week without finding it. The two springs which hold the brushes against the commutator will sometimes be of unequal strength. When this occurs the sound of the horn is materially affected and as a result the ragged sound just mentioned is heard. It is very readily distinguished from the correct clear note. The cure is effected by bending back with a screw driver the spring which seems to project farther than the other. This is of course done with the bottom cover plate removed. It may be necessary to bend the spring back several times before the correct balance between the two screws is reached.

A rather weak sound, also of a somewhat ragged nature, is heard when the two brush springs are on the same side of the brush. Looking towards the outside of the commutator with the brushes vertical, the upper spring should be on the right of the upper brush holder while the spring is to the left of the lower brush holder. The spring can be turned about with a screw driver after the bottom plate is removed.

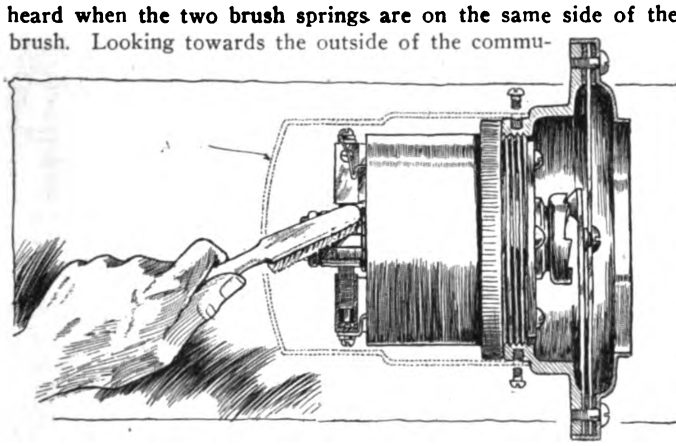

Fig. 3—Remove cover A, to reach commutator

Broken Parts Need Replacement

Some of the instruments returned to the factory for repairs come back because the owners have broken the screws either of the binding posts or of the commutator shaft. The remedy for breakages of this nature is obviously in replacing the broken parts. One broken or loose part which can be found by the horn giving forth a rattling sound is the anvil on the diaphragm. The toothed wheel strikes against this anvil which is riveted to the diaphragm. When the anvil is loose the diaphragm ceases to be positively driven and as a result the rattling sound is heard.

The current consumption of the signal should be watched at times. If the horn is in good condition it should draw from 6 to 7 1-2 amperes at 5 1-2 volts, while the Klaxonet should take about 2.4 amperes. If either of these instruments should draw a noticeable amount more current than what is required the car owner should send it back to the factory. It will occasionally happen that there will be a short circuit through several windings of the armature and that the efficiency of this will thus be materially cut down. This is immediately shown on the ammeter and is something which has to be taken up at the factory before satisfactory repairs can be guaranteed.

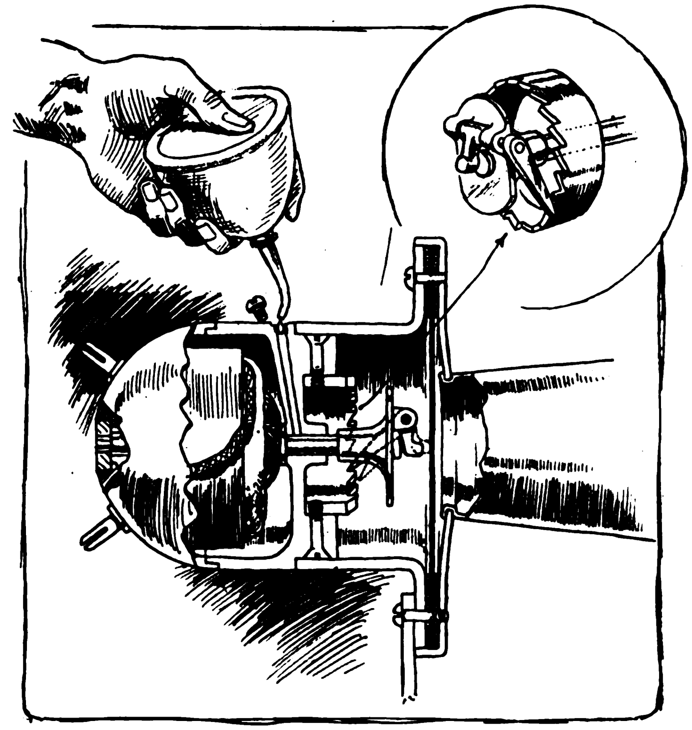

Fig. 4—Typhoon horn must be clean

All these difficulties, however, except the neglecting of the lubricating system and perhaps a slightly mal-adjusted rotor, are rare as compared with the number of times that the horn is suspected when the trouble really lies in the fact that the batteries are exhausted. If the batteries are kept up to the proper strength, splices in the wiring carefully made and two drops of cylinder oil put weekly into the oiler on the top of the case, there should never be any difficulty. The oiler takes care of the ball bearings in the cover plate which carry the shaft of the commutator.

Typhoon Horns Must Be Clean

What has been said regarding the care of the Klaxon could well be repeated in reference to the Typhoon horn. This excellent signal will suffer from a lack of oil in the same manner as any other motor. As may be seen in Fig. 4, special provision is made for oiling the shaft of the motor by removing the screw in the side of the case and allowing a drop of oil to flow down the channel depicted in the illustration. The bearing points are shown in the sketch so that it should be an easy matter for anyone to appreciate where the oil is needed. According to the makers of the Typhoon horn, the greatest trouble they have is that some of the users neglect to renew the dry batteries after they have once become exhausted. The same applies to storage batteries where they are employed. The tone of the horn will become weaker and weaker when the batteries are beginning to run out. A temporary cure for this lies in turning the contact screw on the back of the horn a short distance to the right. This will bring the contact points together and result in a louder tone for a short time. After a while, however, the tone will again run down. When the loudness of the note starts to diminish it is better to have the storage batteries recharged at once or, in case dry batteries are used, to renew these without delay.

Water will often get into a horn and rust the diaphragm, especially if used in the country near sea level. This may be replaced at a very slight cost and a better tone will result. The rusty diaphragm will give forth a heavy sound which is very much unlike the clear, penetrating note of a properly adjusted and clean horn. To remove the diaphragm, take out the small set screws which pass through the flange at the end of the projector and lift off the latter by a straight pull. This will expose the diaphragm, which can be taken off and replaced with

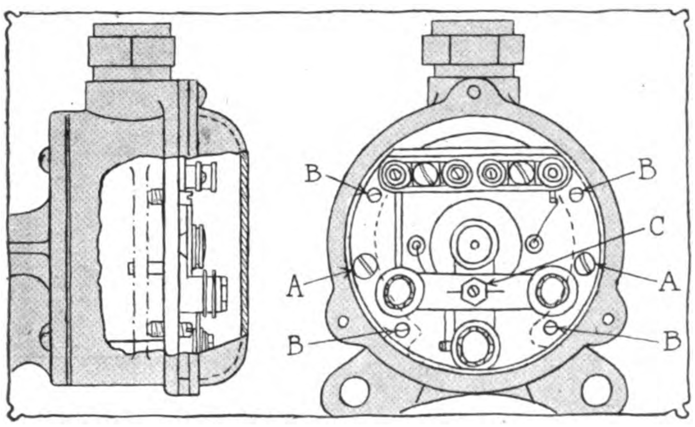

Fig. 5—Points of adjustment on Holtzer-Cabot horn

a new one at very small cost. Washers are put above and below the diaphragm to hold it away from the metal as shown in the illustration. These must be carefully replaced when the new diaphragm is inserted or the tone of the horn will be destroyed and any water that works its way into the horn when the car is being washed or is out in a rainstorm will get into the electric motor and wet the wiring, thus causing a short circuit; as the windings on the armature are not calculated to withstand the effects of moisture cleanliness should be the keynote in horns of this type and the same precautions should be taken as have been enumerated for the Klaxon.

Care of the Newtone Signal

The same directions will apply to the Newtone horn, another typical motor-driven warning signal. For cleaning these signals a toothbrush is a useful article. It should be dipped in gasoline and applied to the point shown in Fig. 3. The brushes become glazed if they are not cleaned occasionally and this insulates them from the commutator either wholly or partially so that the efficiency of the signal is destroyed. A little gasoline once a month will alleviate this and will keep the signal loud and clear. To remove the cover of the Newtone horn, this part being shown by the dotted lines in the illustration, it is only necessary to remove the little screws which are shown lifted from their position in the sketch. What has been said concerning proper battery strength on the other horns can be said regarding the Newtone as well as every other electric horn whether it be vibrator or motor-driven. A periodical inspection once a month of batteries and horn will keep them always in good condition. It will not take long; the only steps necessary are the removal of the cover and the brushes and then the use of the tooth brush with a little gasoline. Once a season some light grease should be applied to the ratchet behind the diaphragm. This can be reached by unscrewing the motor and removing it from the body of the horn. To adjust the sound to its desired pitch the motor is either screwed in further for a heavier sound or backed out for lighter sounds. When replacing the brushes care has to be taken that a substantial connection is made between the wire and the brush holder, as a poor connection here would result in an absolute failure of the horn in case the wires were shaken off the binding post.

Very similar in appearance, though in reality an entirely different type of horn, is the Sireno. When the cover is removed the commutator and brushes are exposed to view, as may be seen in Fig. 2. The directions as to keeping the horn clean at these points and maintaining the proper voltage in the batteries which are used for the purpose of driving the motor in the horn are exactly the same as for the other types of motor-driven horns which have been previously taken up. Repetition is unnecessary, although it may be said in passing that the diaphragm of this horn, being of an entirely different shape on account of the siren principle upon which it acts, needs different treatment. The diaphragm in this case rotates, the sound being given by a number of vanes in the diaphragm which send the air through perforations in the housing of the horn. These vanes and perforations should remain open and clean in order that the horn will reach its full efficiency, for the sound depends upon them to a great extent. They are not very apt to become clogged if the horn is mounted high, but should it be on the lower part of the car in reach of splashing mud, this warning should be borne in mind.

A point which the makers of motor-driven electric warning signals have found difficult to emphasize to a sufficient extent to cause the users to heed the advice is the matter of wiring. In the first place a set of at least five dry cells should be used with all these signals. They all work best with a six-volt current. But the mere connecting of five 1 1-4 volt cells in series will not assure the operator that he is going to get a current of proper strength at the horn. The wire must be large enough to carry the current, the connections must be perfect in order that there be no resistance of any importance in the circuit. Each poor connection will cut down the voltage to a remarkable extent and where one is dealing with a current of 6 volts to

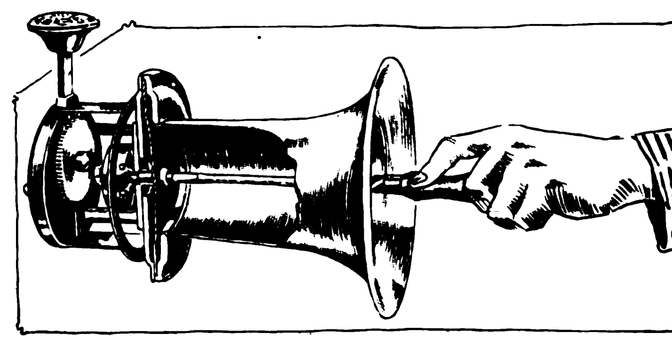

Fig. 6—Showing tone adjustment on the Long horn

start, it is an exceedingly easy matter to allow this current to drop to 3 volts by the time the horn is reached. Protected wire should be used, as there is always more or less chafing against projecting parts, and when the car is running rapidly for a distance it does not take long to penetrate the toughest insulation. It is always a good thing to have the battery near the horn. The loss of current between the cells and the horn will then be minimized. The button operating the horn should be placed so that it may be reached without taking the hands from the steering wheel. Obviously the placing of the horn button on the steering wheel is the most logical solution of the problem of finding a place where the electric horn can be operated at an instant's notice.

In summing up the care of motor-driven electric signals the following directions should be kept in mind: Keep the commutator clean by using a little gasoline on a brush once a month: a touch of vaseline on the commutator once a month will keep it in good condition; see that the internal connections do not permit of a short circuit within the instrument; do not use a higher voltage than the maker recommends; keep the sound adjusted to a proper pitch, in most motor-driven horns where the adjustment is too tight an unnecessary amount of current is consumed; see that both brushes bear equally hard against the commutator; make careful wiring splices; maintain the proper battery strength.

Caring for Vibrator Type Horns

Electric horns of the vibrator type are simple and efficient. They work on the same principle as the buzzer, a magnetic vibrator action actuating the diaphragm and thus producing the sound. The Tuto horn is an example of the vibrator type and is very representative of this class of horn. The mechanism is shown in diagrammatic form in Fig. 8. There is but one moving part and that is the armature. It is designated by the solid and dotted lines which show the path through which it moves. As may be seen, the armature is supported on a solid spring, which through its natural action allows the moving armature to impart a hammer blow to the rod reaching to the diaphragm. Each time the diaphragm is struck a sound is sent through the projector of the horn and the only thing necessary to maintain a solid stream of sound is to have the successive blows upon the diaphragm produced in sufficiently rapid succession. This is accomplished by the electro-magnetic or solenoid coil shown in the illustration. As the battery circuit is closed the current flows through the contact points and coil, magnetizing the bar of soft iron that is enclosed in the coil. The magnet attracts the armature sharply towards itself and causes the blow to be struck on the diaphragm stud as just described. In pulling the armature towards the diaphragm the connection at the contact points is severed and the circuit is broken. The soft iron core is demagnetized and the spring causes the armature to fly back to its original position, again closing the circuit and allowing the same cycle of events to again take place.

How to Adjust a Vibrator

With this explanation of the mechanism of the Tuto horn and all others of the vibrator type, it may be perceived that the factor of lubrication does not enter into this class of horn. There is one point, however, which will require adjustment from time to time. This is the contact screw, which has been specially designated in the illustration, Fig. 8. The screw is held securely against turning under the vibration of the car by a clamping screw which must be loosened before any adjustments can be made. This can be done with an ordinary screw-driver in a few minutes' time. Usually a quarter turn of the contact screw in a clockwise direction will be all that is necessary to compensate for the wear of an entire season. When this has been done the pressure of the push button will indicate whether

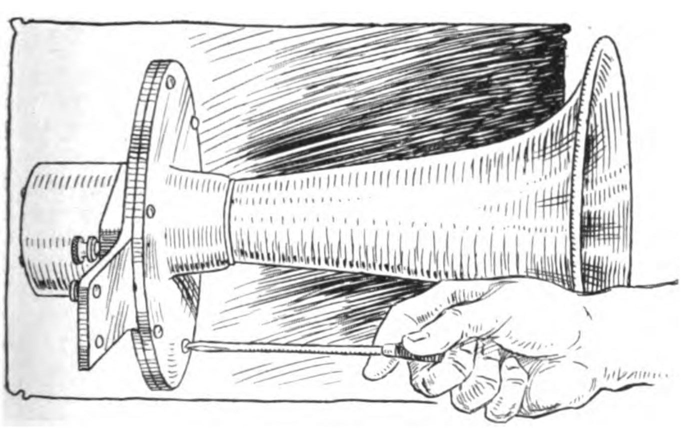

Fig. 7—Removing diaphragm from the Oneita vibrator

the adjustment is correct or not by the tone which is given forth. The low tone of the horn should be given instantaneously on the slightest pressure of the horn button, while the loud tone which is given when the button is fully depressed, should be smooth and clear as compared to the ragged tone noticeable with an incorrect adjustment.

The stud which transmits the blow of the armature to the diaphragm is fitted with an adjusting device which is more useful to the factory assembler than to the owner of the horn, for after it is once set at the factory there is hardly ever any necessity for the owner to touch it. The office of this adjustment is to regulate the length of the stud so that it is impossible for the armature to strike the pole pieces of the magnet. When this happens it is easily noticeable because the armature fails to produce a loud clear note, a ragged tone of very little penetration and loudness resulting. The adjustment is made by turning up or down as required, the hexagonal nut located on the end of the rod making the rod longer or shorter.

In the case of vibrating horns as well as for the motor-driven type it is well to get after the current consumption from time to time with an ammeter. Each horn is designed to draw a certain amount of current and when the current taken is above that quantity the reasons should be found, for not only is the horn costing more money to operate than it should, but it is no doubt delivering a tone which is not as efficient as it would be were the defective points corrected. Besides this, in most cases where too large an amperage is drawn, the life of the instrument is seriously threatened as matters go from bad to worse. The Tuto horn is designed to take not more than 1 ampere on the low note and not more than 2 amperes on the loud tone. A little less than this should be registered on the ammeter for either the loud or low tone, as these are the maximum allowable consumptions. When the amperage becomes high look at all connections and see that they are perfect; see if the contact points are adjusted properly and that they are flat and not ragged. A few touches with a fine file can easily regulate this.

A vibrator horn which has been carelessly constructed can give a great amount of trouble in spite of its simplicity. This statement is uniformly agreed to by the experts in the manufacturing plants of the better class of vibrator horns. The greatest trouble will be caused by the use of poorly selected or cheap materials. Some points which must be watched carefully can be here taken up.

The sticking of the contact points after the horn has been used for some time is often caused by the welding action of the heat generated by the electric arc which is drawn between them. Unless special precautions are taken at this point by using special metal which will not be so apt to soften materially under the influence of the current the operator will be surprised to note the sudden failures of the horn to work. Where good material is used, as in the several well-known vibrator horns now on the market, the hot electric arc instead of welding the points together will clean out the deposit of foreign material from between the points. Nevertheless these points should be kept clean by the owner of the horn for there will always be a deposit remaining even when the carbon is burned off the points. The inability of the vibrator horn to maintain its adjustment shows that the particular type of horn which gives this trouble has poor material in the contact points, and when this is noticed it may just as well be discarded. In the better types of horns there is sufficient contact material to last as long as the best cars if the adjustment is made occasionally. Wear is taken care of in the Tuto horn by the screw designated in the sketch. Other horns of the vibrator type all have some similar means of taking up what wear occurs in the contact points.

Monoplex Also Has Vibrator

There is no excuse for the breaking of springs in horns of this type, and cases of this kind occur only in the poorest horns. When it does happen the only remedy for the trouble is to buy a new spring and fit it in place. Where a spring should break in a vibrator horn, however, the purchaser should demand a new instrument. Cases of this kind never happen with the better grades of horns, and it is after all a matter of economy to purchase the best in this line, as the horn is an

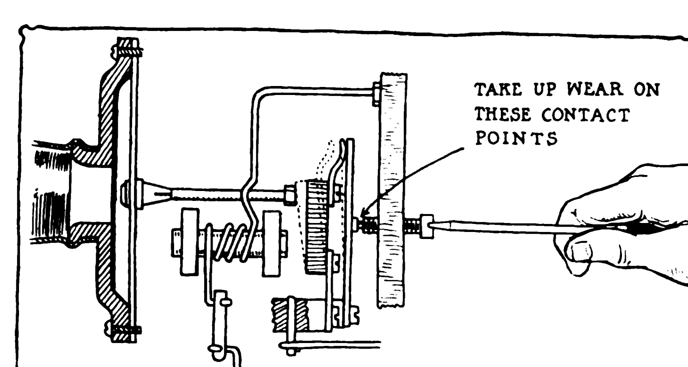

Fig. 8—Diagram of Tuto horn, showing contact adjustment

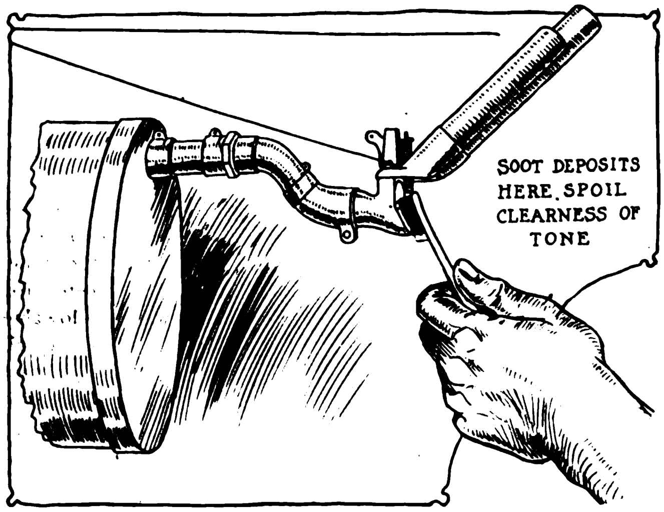

Fig. 9—Point to watch on Waymaker horn

accessory which may prove a friend in dire need and failure on its part in some such time may mean disaster. What has been said regarding the breaking of springs may also be noted regarding the failure of the diaphragm to retain its shape. The use of the best metal is necessary here in order to resist the crystallizing effect of the rapid succession of hammer blows.

As in the motor-driven horns, the advice given in regard to one signal applies perfectly to all the others of the same type. The care of the Monoplex horn does not involve any features which are not brought out under the discussion on the Tuto horn. The brass cap on this hoin is removed by taking out the small machine screw which will be seen on the side of the horn. The cover can then be pulled off, exposing all the mechanism, which can be taken care of by the owner. No more dissection than this should be practised on any horn if the owner does not desire to find himself in the position of the man who took his watch apart and when he had put it together again found that he had simplified the mechanism by having two wheels left over.

No lubrication is required for a vibrator horn. Most makers do recommend that the user employ a fine sheet of emery paper at the beginning of each season for the purpose of dressing down the contact points and making them flat and clean. This ought not to take anyone more than 5 minutes. After this is done and the contact screw taken up to its proper adjustment the horn should require no other attention during the season. Outside of the horn, however, the batteries and connections must be watched, as has been explained above.

Mesco Horn Has Unique Feature

The Mesco horn is distinguished in the class of vibrating horns for its four independent magnets. The armature is located above these and the vibration is set up in the usual manner by automatically interrupting the circuit. Good connections both within and outside the horn are necessary in order that the action be a success. To inspect the horn remove the four small screws in the cover and lift it off. The whole mechanism will then be open to view. The contact screw need not be turned more than once a season. At this time, however, they should be examined to see that they have worn flat and not round. There is an idea current that the points wear in the same way as a carbon in a lamp. That is, that one point becomes hollow or cup-shaped while the other acquires a point on account of the flow of metal betwen the two points. This may or may not be true, but the fact remains that the best way to maintain the horn at its best efficiency is to dress these points up at the time of overhauling the car.

The Holtzer-Cabot adjustments which are illustrated in Fig. 5 are like all the other vibrator horns in principle although the arrangement is a little different. Referring to the illustration, the method of procedure for adjusting the horn for tone and loudness would be to first loosen the screws shown at A, and then moving the plunger away from the diaphragm by turning in the set screws B. Each of these screws should be turned in an equal amount to secure uniform adjustment. The vibrator screw should next be adjusted until the proper speed of vibration is secured. The plunger is then gradually moved up closer to the diaphragm until maximum loudness is obtained. This is accomplished by turning the screws B in a counter-clockwise direction until the desired tone is obtained. To lock the adjustment the screws A are tightened up.

The diaphragm in the Holtzer-Cabot horn, as well as in practically every electric horn made, can be removed by removing the screws which surround it, as shown in Fig. 17, where the Oneita horn, a representative horn of the vibrator class, is depicted. The diaphragm on several of these horns is arranged with a small piece of metal in the center known as an anvil. Should the anvil become broken, bent or loose it is generally necessary to replace the whole diaphragm. This is very readily accomplished by taking out the screws designated in the illustration and lifting off the washers which are placed around the circumference of the diaphragm to hold it in place without metallic contact. New diaphragms are very cheap and are easily installed by simply laying them in place and replacing the screws.

Remove Soot From Exhaust Horns

The Long horn is a vibrator horn not operated by electricity but by pressure of the hand or elbow upon the plunger. The plunger actuates a gear wheel in the interior of the horn; this wheel rapidly revolves, being carried along by a heavy flywheel. The care of this horn is very simple and consists in a simple replacement of any part or parts which should become worn. The teeth on the ratchet of the plunger may be broken by a direct shock to the plunger, but with ordinary care and usage the horn should last as long as the car.

The next style of horn to consider is that operated by the exhaust gases. The Aermore, Jericho, Exo, Gabriel, Nightingale, Apco, and other types of exhaust horn all depend on the pressure of the exhaust gases for their operation. The two greatest problems to deal with in all exhaust horns is to keep them clean and to install them properly. Most of the things which crop up in the care of exhaust horns can be readily cured by means of a small brush and a little kerosene oil. The simplicity of this type of horn and the infrequent attention which it requires are among its commendable points, and the mere knowing how to get at the horn when it is fouled, as they nearly all become if the motorist has been burning too much oil for a long time, will go a long way in preventing trouble from the accumulated deposit.

A toothbrush forms a handy instrument to use in removing the carbon should it be found that the vents are choked with this most troublesome product. As long as the bristles on the

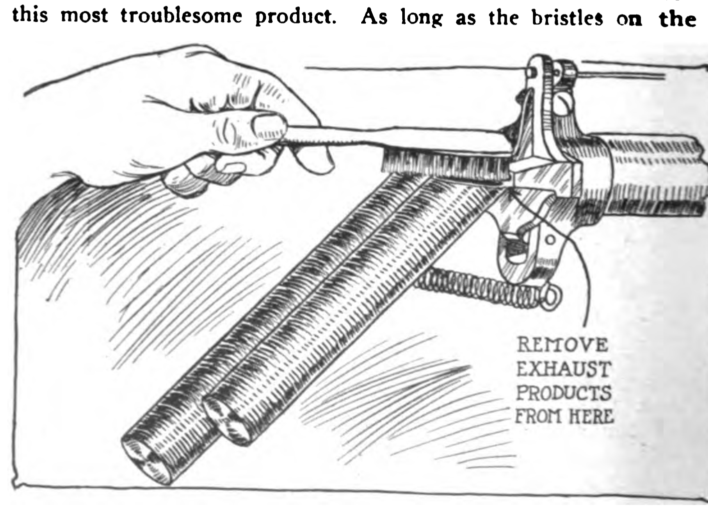

Fig. 10—Kerosene on a toothbrush helps the tone

brush are stiff, however, it will be satisfactory for this purpose. Either gasoline or kerosene will dissolve the products which gather in the pipes.

It often happens that the cut-out valve located in the pipe between the motor and the muffler becomes warped from the heat of the exhaust or seats defectively from some other cause. This will permit a large portion of the gases to escape at this point, and besides being noisy allows the pressure to fall off so far that the sound of the horn is impaired. In case trouble is had in getting insufficient sound it would be wise to thoroughly examine the muffler and its connections. It will very often be found that the joints are loose and that a large part of the gases escape through this means. This will necessarily interfere with the action of a horn that depends for its operation on the volume of the exhaust. In case cables are used in the operation of the horn there is always a possibility of stretching. The slack should be taken up as it occurs in order that there be no lag in the application of the signal.

Never use a file, screwdriver or other hard instrument of a like nature which is apt to bend or mutilate the language plate or lips of such horns as the Gabriel; a stiff brush with kerosene or a quill toothpick moved back and forth through the serrations in the edge of the language plate will restore the natural tone to the horn. Washing this type of horn with water for the removal of dust will do no harm, but the use of kerosene or gasoline is better as these are better solvents.

Jericho Automatic Has Magnetic Device

The Jericho Automatic horn is the same as the Jericho with the added feature of an electric magnet which serves to operate it. The horn, while it is actuated by the exhaust, is operated by a push button which may be placed on the steering wheel or any other desirable place. The electric magnet has a movable plunger attached to the hinged lid of the horn. When the operator desires to give a warning signal he presses the button which closes an electric circuit through a solenoid coil. This lifts the plunger which operates the horn by shunting the exhaust gases through the proper passage. The maintaining of the battery strength and the cleanliness of the horn is about the only care these horns need, except that careful wiring is necessary.

The bulb horn, in spite of its conceded simplicity, requires some care also if it is desired to maintain it in its proper condition. The worst enemy of the horn is water, which often enters while the car is being washed. When screens are used over the horn do not allow them to be caked over with metal polish or mud. Keep them clean.

While many automobilists do not expend much effort on the care of their horns, a little reasoning is bound to bring out the idea that such a course is a mistaken one. A good horn goes a long way toward avoiding accidents on the road and saving the car owner large sums of money which he would have to spend if personal or property injuries are caused by his car.

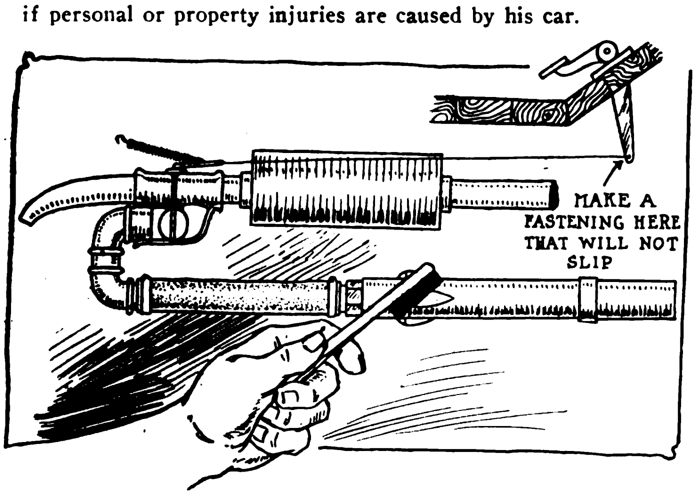

Fig. 11—Gabriel horns are benefited by cleaning occasionally

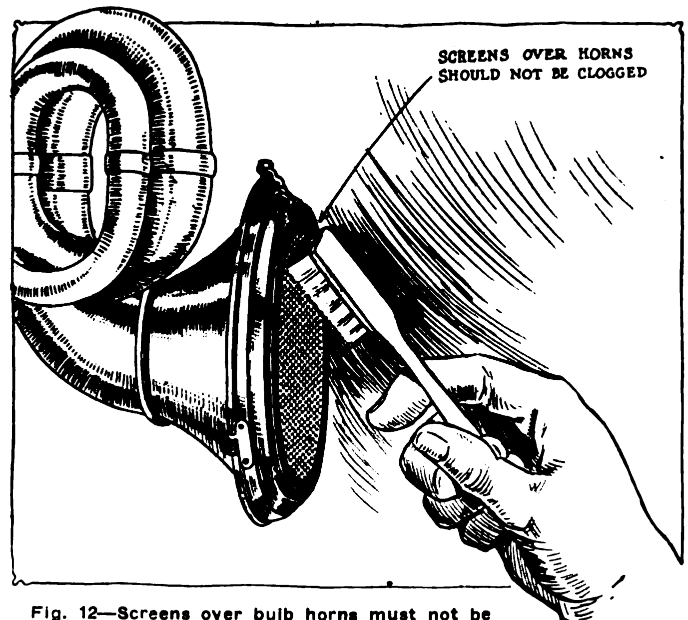

Fig. 12—Screens over bulb horns must not be clogged

Harking Back a Decade

FROM *The Automobile and Motor Review,* August 9, 1902:

The 100-mile endurance test held under the management of the Chicago Automobile Club last week was one of the most interesting, profitable and important events in the brief annals of western automobiling. There were twenty-eight starters. Only one serious mishap occurred and it was caused by fire which destroyed the Elmore contestant. The course was to Waukegan and return. Nine cars were awarded blue ribbons and the main cup was won by F. X. Mudd's Winton.

October 9 will see the start of the reliability test of the Automobile Club of America. This will allow the tourists to spend Sunday in Boston and start the return trip on Monday morning. The finish is scheduled for October 15. Secretary Butler is formulating rules to cover the contest.

One of the chief lessons learned in the recent Paris-Vienna race was that laxity in the application of the rules concerning controls is a serious matter. The fact of the arrival first at control was given a fictitious valuation and numerous violations of the rules in this respect were noted, especially where some contestant failed to stop at controls and then presented himself at the head of the line for final checking.

Cincinnatians have made a sharp market for automobiles this season, despite the hilly topography of their city. There are now ninety automobiles owned and driven in the Queen City.

Details of New Ford Racer

Details of the racer being made by Henry Ford have been given out. The car will have a four-cylinder motor with cylinders 7 1-2 by 7 1-2 inches, designed to be run up to 1,000 revolutions per minute. There is only one speed gear, but by throttling down, it is believed the car can be made to go as slow as 15 miles an hour at 150 revolutions. The maximum speed is problematical. The car is not intended for use on streets or highways.

Orders to sell the factory plant of the Gasmobile Company of America, located at Marion, N. J., have been signed. The unsecured creditors hold claims amounting to about $170,000.

Members of the Milwaukee Automobile Club have started a movement to train horses to familiarity with the motor vehicle. The plan includes the renting of vacant lots in the city where the horses can take instruction.

William K. Vanderbilt, Jr., recently made a flying mile in 48 2-5 seconds on the road near Chartres, France. This is 3 2-5 seconds lower than the former world's record held by Fournier.

Some Points Regarding Gasoline and Kerosene—Methods of Brazing Hard Metals—Adapting Six-Cylinder Magneto to Three-Cylinder Motor—Diagnosing Throttle and Spark-Plug Troubles—Some Tire Tips—Steering Gear Information

Two Pointers to Remember

EDITOR THE AUTOMOBILE:—I have a 5-passenger car which has given me a great deal of trouble. After having repeatedly balked I decided to thoroughly overhaul it. When I came to the switch block, I found a binding screw loose. The connection wire would fall from one side to the other and in this way would make contact at times.

Then a leak occurred in the gasoline line. In a short time I found that the three screws in the flange of the carbureter were loose. Now I have more trouble. If I run my car any distance and stop for 10 minutes or more, I have trouble in starting again. After filing the coil points, it will run again for a short while.

In a recent issue of THE AUTOMOBILE, a correspondent stated that it would help if the units or the wires were changed. How do you do this? I tried to change the wires from the timing post to the spark post on the coil, and the plug wires to the timer posts, but it would not spark.

Jacksonville, Ill. J. A. HASP.

—The wires need never be turned around on the vibrator points or any other tampering done if the proper adjustment is maintained at all times. The correct method of making the adjustment is outlined in another letter in this issue entitled, "Motor Won't Throttle Down."

Regarding Hydro-Carbon Fuels

Editor THE AUTOMOBILE:—Will you kindly answer the following questions?

1. What is the viscosity of 68-degree gasoline as compared with water?
2. What is the viscosity of kerosene as compared with that of water?
3. What is the accepted chemical formula, or rather the formulas, of the constituents of gasoline?
4. What is the formula or formulas of the constitutents of kerosene?
5. I understand one volume of liquid gasoline and about 11,000 volumes of air make the highest explosive mixture. Is this correct?
6. What relative volumes of liquid kerosene and air form the most explosive mixture.
7. What temperature is the boiling point of gasoline?
8. What temperature is the boiling point of kerosene?
9. How many B.t.u. are in a gallon of 68-degree gasoline?
10. How many B.t.u. in a gallon of kerosene?
11. What is the average specific gravity of the kerosene now obtainable?

Owensboro, Ky. A. READER.

—The following are the approximate values which you desire: (1) 0.8; (2) 2.5; (3) C^7H^{16}; (4) $C^{11}H^{24}$; (5) Yes; (6) 1 to 13,000; (7) 120 degrees Fahrenheit; (8) 300 degrees Fahrenheit; (9) 124,000; (10) 134,000; (11) From .800 to .806.

For Brazing Hard Metals

Editor THE AUTOMOBILE:—Would thank you for the following information: What is used for brazing hard metals such as cast or other hard chilled metals?

Donnellson, Iowa. W. J. SCHMITT.

—The method employed with such metals first thoroughly clean by scraping and filing the two surfaces to be brazed together. Borax is then brushed on the surface to prevent oxidation. The parts to be joined are then pressed tightly together and the heat applied by means of gas flame in a built-up brick oven or any other method the repairmen desires to use. Where the joints do not have to stand a heavy strain use four parts copper and three parts zinc for your spelter. If considerable strain is to be borne, use three parts copper to one part zinc. For average work use equal parts copper and zinc.

Can Use Six-Cylinder Magneto

Editor THE AUTOMOBILE:—I have a three-cylinder, two-cycle engine which has stood some very hard service and have no trouble except with the battery-and-coil ignition system.

I have a six-cylinder, four-cycle magneto. I would like to install and would like your opinion as to whether to run the magneto twice engine speed and use two sets of spark-plugs. What effect would the former have, as I am afraid the latter would run

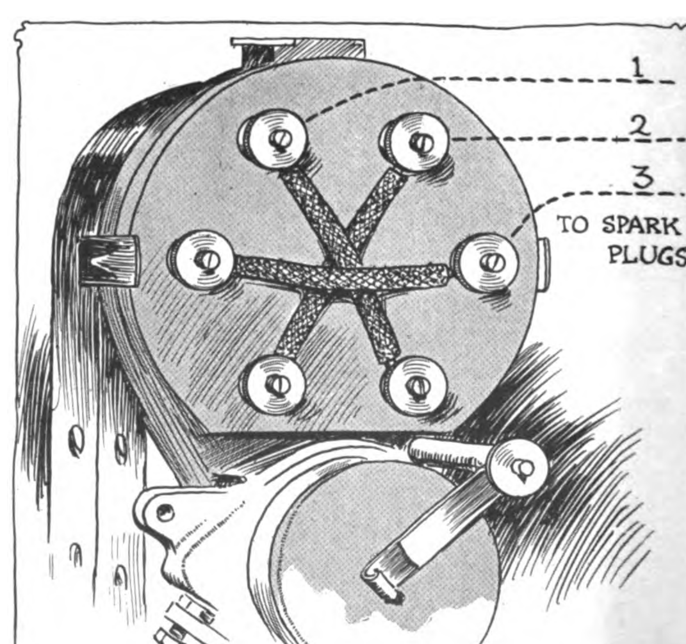

Fig. 1—Cross-connecting points on six-cylinder magneto to adapt it to a three-cylinder motor

the magneto too slowly? Kindly give the information in an early issue of The Automobile.

Chicago, Ill. L. G. Burke.

—You can use the six-cylinder magneto by cross connecting the points on the distributer which are diametrically opposite Fig. 1. This will give you three leads to the spark-plugs and you could use three plugs instead of six. The magneto should be driven at 1 1-2 times the engine speed. The gear ratio of armature to distributer is 3 to 1 so that you would get the spark at every 120 degrees which is the correct crank angle for a three-cylinder motor.

Motor Won't Throttle Down

Editor The Automobile:—I have seemingly a difficult problem on my automobile.

A Ford car, No. 34940, model 1911, was always rather hard to start, but by priming carbureter (Kingston), and turning needle valve open a half or full turn, could usually be started except in very cold weather by a few turns of crank. For a few weeks it has been impossible to start it except by injecting gasoline directly into the cylinders. After being started it will run fairly well from fifteen miles an hour up, but if throttled below that point the motor dies. Mechanics here are nonplussed. Ignition has been thoroughly gone over and tested, new batteries, installed, to try and facilitate starting, commutator taken off and cleaned, cylinder head taken off and carbon removed and valves ground. Timing gear was inspected and marks on gears found to correspond. Latter had not been touched since car left factory. We turned motor slowly to see if valves seemed to be properly timed. Previously we tried a brand-new Holley carbureter, and if there was any difference, the motor was even harder to start. When the air was shut off and the engine cranked there would be a suction immediately followed by a blowing out of gas from the carbureter. With the Kingston the spray blows out of the air intake. Have wound intake manifold and saturated with gasoline hoping to detect a leak. No discovery. The cylinder head joint leaks a little oil and water though bolted down tightly, but gasket seems in good condition.

Watertown, N. Y. A. C. J.

—In the first place the probabilities are that you have the contact points on the vibrator adjusted down too tightly. The screw which regulates the vibrator should be turned down until there is no vibration at all between the two points and then turned up until it just begins to vibrate. After it has reached this point give the screw an eighth of a turn more which will give a light adjustment and one which will not cause the contact points to burn out quickly and will enable you to start without racing the motor. The carbureter adjustment is also possibly incorrect. It must be remembered that the carbureter should give a rich mixture to start and if it fails to do this will always render starting difficult.

Offense Punishable in All States

Editor The Automobile:—Are there any states that make it a misdemeanor, punishable by fine, or imprisonment, or both, to throw broken glass or bottles in public highways? It seems to me that some action ought to be taken in the matter, in this part of Virginia, at least. Motoring is getting to be one continual eye strain to avoid broken bottles that appear to have been thrown in the road for the express purpose of ruining someone's tires. This is a small town, 6 miles from a railroad and we have had running now, about two months, a 2-ton Packard truck that makes the round trip daily between this place and Roanoke, our nearest town, 18 miles distant. The truck carries both freight and passengers, and so far has proved to be one of the greatest conveniences this place has ever enjoyed. I saw, yesterday, a chunk of rubber that would weigh at least 4 or 5 pounds that was cut completely out of one of the dual rear tires by a beer bottle that had been thrown in the road by some hoodlum possibly for that identical purpose.

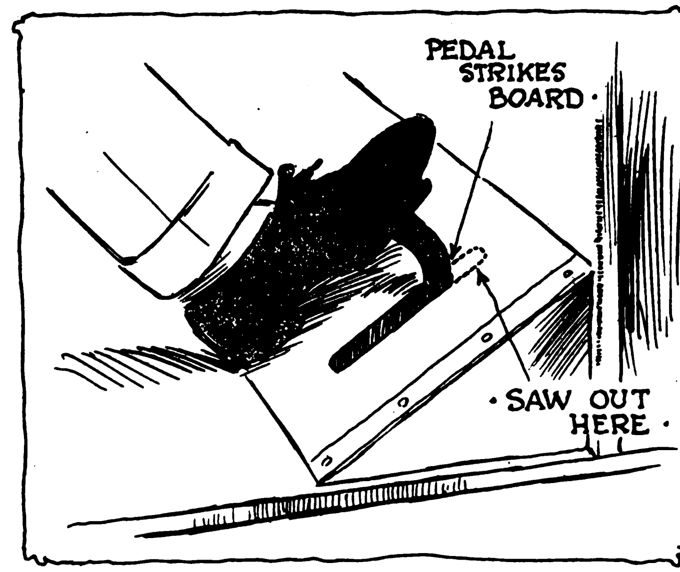

Fig. 2—Cutting away floorboard to allow of free movement of clutch pedal

Surely motorists are due some consideration from the general public and should not be subjected to these needless and costly annoyances.

Fincastle, Va. E. M. Miller.

—Even though the offense is not specifically mentioned in the statutes there is some law in any state by which an offender of this nature can be brought to justice if detected.

Had to Cut Away Floor Board

Editor The Automobile:—I saw in a recent issue of the The Automobile that you advised a reader to examine the floor board and see if the slot was deep enough to allow him to fully disengage his clutch. As I had the same trouble I looked at the floor board on my car and found that it had to be cut away as shown in the sketch, Fig. 2. It is remarkable how one will overlook the obvious when searching for troubles in a motor car. I had not been able to shift gears satisfactorily because the clutch lagged a little and I could not find the trouble until I noticed it mentioned in your columns.

New York City. Interested.

One Spark-Plug Gives Trouble

Editor The Automobile:—I have a 1911 high-grade car which has been giving me trouble since I purchased it new about a year ago. The spark-plug in the third cylinder persists in oiling up, while all the others remain perfectly dry and clean. A change of the plugs or the use of new ones makes no difference. A test shows the current to be just as strong on this cylinder as the others. The oiling system is a force-feed and this cylinder receives exactly the same amount of oil as the others. The cylinder seems to fire until it becomes too much chocked with oil and then a cleaning out with a little gasoline rectifies it.

I finally concluded that the cylinder might be scored or cracked, and for that reason was letting up too much oil. So the engine was taken down and a new cylinder and rings were put in, but the trouble still remained. Can you give me a possible solution of the difficulty?

Ignition is by Bosch high-tension magneto. No batteries are used. A Hancock oiler with sight-feed to each of the internal case-bearings is used, from which the oil flows through the hollow crankshaft to the connecting rod bearings where it is thrown off and lubricates the cylinders, next to the bottom of the crank case, where it is taken up by splash. The compression on all cylinders seems alike.

Which is the best for the motor; using a mixture as lean as possible, just so there will be no popping back to the carbureter,

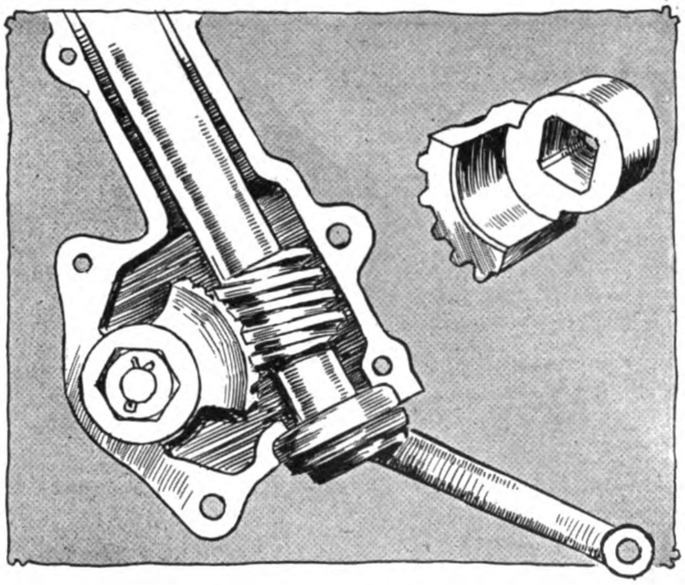

Fig. 3—Illustrating operation of worm-and-sector steering gear

or the use of a mixture which gives a maximum of power.

Round Top, N. Y. J. F. W.

—You can be reasonably sure that the oil is getting past the piston and working its way up into the combustion space. If a new cylinder did not cure the trouble it would be advisable to get an oversize piston as the fit between piston and cylinder is evidently at fault. Any looseness existing at the lower connecting rod bearing might also cause too much oil from the pressure feed to be thrown up into the cylinder. It would be well to examine this before changing the piston, although the probabilities are that you have an undersized piston which passed the inspection department without being caught.

Skips When Running Slowly

Editor The Automobile:—I have a 4-cylinder motor that skips when throttled down, but runs all right when opened up. Can you tell me the cause?

Worcester, Mass. W. A. D.

—The trouble is either in the carbureter adjustment or in the magneto. If you will try the car on both the batteries and magneto and see if it skips only on one of the two ignition systems you will eliminate one of the two possibilities. Should the trouble only appear when operating on the magneto you will know that the magnets require recharging, for the spark generated at low speeds is not hot enough to fully ignite the charge. Should the trouble still continue whether you run the car on battery or magneto, you will know that you are not getting a rich enough mixture at low speeds. As you do not mention what make of carbureter you are using it is not possible to advise you how to make the adjustment beyond the fact that the spray aperture should be opened a little.

Asks a Few Tire Questions

Editor The Automobile:—Will you kindly answer the following?

1. Does it do a tire (molded or wrapped tread) any good or harm to use a tire paint?
2. What is the proper size tire to use on a car weighing 4,100 pounds?
3. How much air should they have in them?
4. What is the best way to carry tubes in a tire trunk?
5. Would it do to wrap them in paper?

San Francisco, Cal. J. Jenson.

—(1) It does not do the tire any damage and certainly increases the good appearance, making the tire look bright.

(2) Anything from a 34 x 4 1-2-inch up.

(3) A pressure of 90 pounds per square inch.

(4) Carry them flat in a box or wrapped in paper and keep them liberally sprinkled with soapstone, graphite or tire talc.

(5) This question is answered under (4).

Some Steering Gear Questions

Editor The Automobile:—In reading over the 1913 car announcements in your paper I find that some cars are using the worm-and-sector, while others are using the worm-and-gear types of steering mechanism. Will you kindly explain the difference between them? I should also like to know what the word irreversible means when used in connection with a description of a given form of steering gear. Is there any confusion on these names?

Tenafly, N. J. F. H. Varian.

—The difference between worm-and-sector and worm-and-gear steering is just exactly as the name suggests. A sector is a portion of a circle while the gear is the whole circle. It is cheaper to make a worm and sector because it is not necessary to cut teeth all around the wheel while the gear has the advantage that when some of the teeth are worn the gear can be moved around and a fresh set brought into action. The two types are illustrated in Figs. 3 and 5 which explain the difference better than words. The word irreversible used in connection with steering gear signifies that the road shocks will not turn the wheels out of the line in which the driver holds them by means of the steering gear. There is no confusion of terms regarding the nomenclature of the steering gear and its parts.

Has an Old 1902 White Steamer

Editor The Automobile:—I have a 1902 White Steamer, seating 5 passengers, and would like to know the following:

1. How many miles an hour was it supposed to run when new?
2. Had it power to run over a sandy road?
3. How many pounds of steam was required to run it?
4. Was that style car a success?

Trenton, N. J. J. McCormack.

—(1) It could go 15 miles an hour over any passable road.

(2) Yes.

(3) It took 300 pounds pressure.

(4) For that time it was a distinct success, especially in that it made use of a condenser which reduced the water consumption to a marked extent.

The greatest success of the White car was reached in the 100-mile A. C. A. run held on Memorial Day, 1902. In this event the consumption of fuel and water were as important as the time spent upon the road and great surprise was occasioned at the small amount of water required to operate the car. At one of the controls the White took on 8-10 cubic foot while the nearest competitor required over 4 cubic feet. The secrets of the success of the White car were the series of coiled pipes which resembled the water-cooling system of a gasoline car and which greatly mystified the officials of the contest until it was discovered that these pipes formed a condenser which allowed the car to operate at a much higher fuel efficiency than had been obtained in any previous car. Dry superheated steam is generated from a boiler which is composed of twelve layers of helically coiled pipes. The temperature of the steam is generally about 800 degrees Fahrenheit.

Horsepower of the R-C-H Motor

Editor The Automobile:—What would be the actual horsepower of an engine with the same bore and stroke as the R-C-H 3 1-4 by 5?

Is the 2-bearing crankshaft as desirable as the 3-bearing shaft?

Wyandotte, Okla. C. R. S.

—The brake horsepower of the 3 1-4 by 5-inch motor, which was obtained from tests made with the motor driving an ordinary two-blade fan dynamometer at the R-C-H factory, was calculated as follows:

The blades were 10-inch x 14-inch and were set at varying center distances, and the horsepower developed at a speed of 1,750 revolutions per minute was 26.

This recorded horsepower did not consider the friction loss in the dynamometer driving shaft, which must have been considerable because of its insecure mounting and excessive vibration at high speeds. On account of the impossibility of setting the fan blades close together, it was impossible to run the motor at a higher speed than 1,750 so that the power developed above this point has not yet been determined.

The two-bearing crankshaft is not as stiff as the three-bearing and therefore the extra bearing length in order to eliminate the tendency toward whipping in a shaft of this nature will have to be made up by the increased length of the two end bearings. Where the bearings are of generous length and the lubrication of the long bushing necessitated by this arrangement is adequately taken care of it would be difficult to say that the advantage rested with either. A two-bearing crankshaft in which the bearings were too short would not last any length of time as it would be impossible to hold the correct alignment.

Wants to Become Racing Driver

Editor THE AUTOMOBILE:—I have driven cars over 40,000 miles and desire to become a racing driver. Could you give me any help?

Chicago, Ill. A. N. J.

—Apply to the Contest Board of the American Automobile Association, Fifth avenue and Thirty-ninth street, New York, for a racing driver's license. You will have to state your experience and answer the questions they put to you. After you have done this and secured your license it is a mere matter of looking for a job.

Plaster of Paris Replaces Confetti

Editor THE AUTOMOBILE:—I have taken great interest in the articles on women drivers, and am therefore sending an account that may be of value to the other readers.

On a 108-mile run, from Camden to Wildwood by the Sea, N. J., only one woman out of eighty-four entrants started. Her passengers were all women. She won third prize, a silver cup, given by the proprietress of the Wildwood Manor.

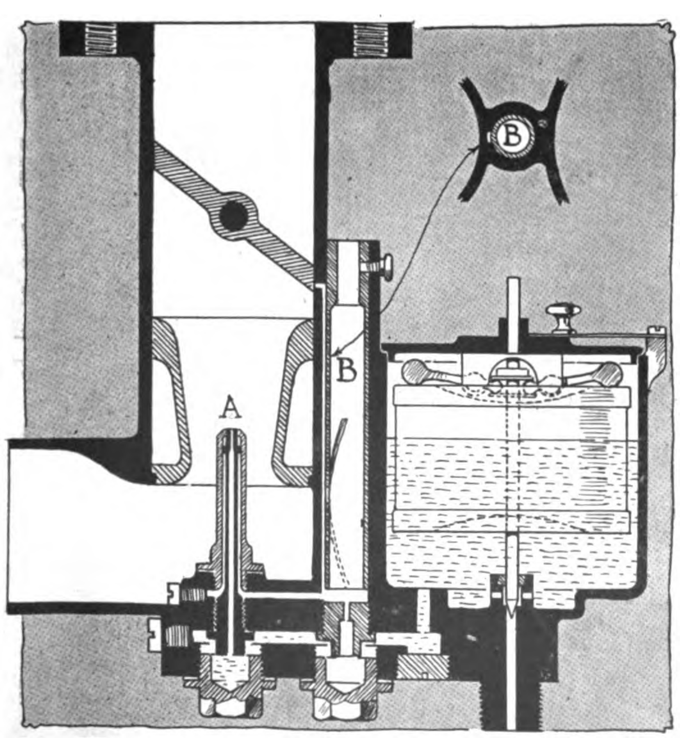

Fig. 4—Cross-section of Zenith carbureter, showing concentric jet

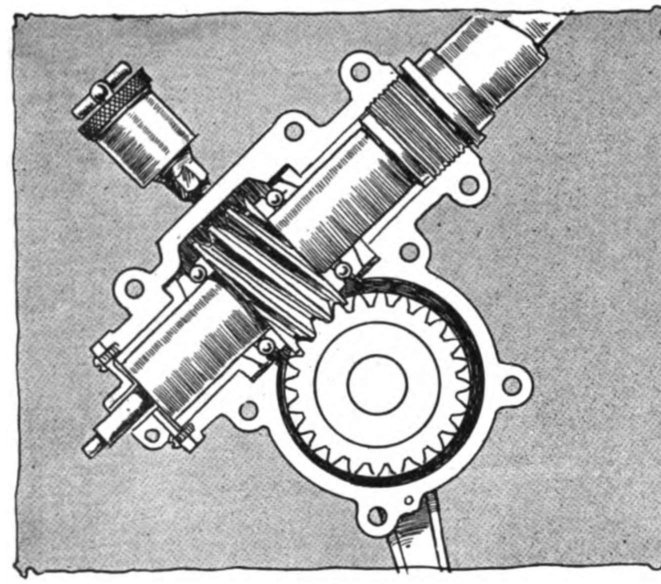

Fig. 5—Illustrating operation of worm-and-gear steering

I have been on all the runs in Philadelphia since the very first and have seen many different methods employed to mark the course, but after a trial on this run, plaster of Paris was found to be perfect, in that it does not blow away like confetti and children cannot pick it up. It will not disfigure the streets and it can be seen a block away, giving an entrant time to slow down for the turn.

Philadelphia, Pa. MARY W. HARPER.

Operation of Zenith Carbureter

Editor THE AUTOMOBILE:—Would you kindly explain to me the action of the Zenith carbureter? I have a car fitted with one of these carbureters but do not quite understand its action, although it is very satisfactory and gives no trouble.

New York City. J. G. RITZ.

—The Zenith carbureter is distinguished from all others by its double concentric jet which is shown at A, Fig. 4, and also by the tube B, a feature which is especially designed for the purpose of rendering starting easy. When the motor is stopped, a supply of gasoline rushes into the tube and remains there until the motor is again started. The level of the gasoline in the tube while the motor is idle will naturally be the same as that in the float chamber. When cranking the motor with the throttle very slightly opened the suction around the edge of the butterfly valve is strong enough to draw the gasoline in the tube through the opening at the edge of the butterfly, making starting very easy. This tube also comes into action at very low speeds, as the suction of the motor is not great enough to keep the gasoline exhausted and, as a result, there is a spray at the inlet near the butterfly valve which really takes on the importance of a third spray-nozzle. The amount of gasoline passing around the tube can be regulated by turning the tube on its axis. The auxiliary jet comes into action after the motor has speeded up sufficiently to suck the gasoline through the passage below the tube besides through the main jet. The faster the motor is running the lower will be the level of the gasoline in the tube B.

Letters Should Be Signed

[THE AUTOMOBILE is holding a few queries and communications which have been received unsigned. If a correspondent does not wish his name published it is merely necessary to state this fact in the letter and a nom de plume will be substituted. As an evidence of good faith, however, it is required that all communications be signed. Those which have been received up to date will be held until the identity of the sender is known. All communications will be answered strictly in the order in which they are received.—EDITOR.]

Great Western Adopts L-Head Motor

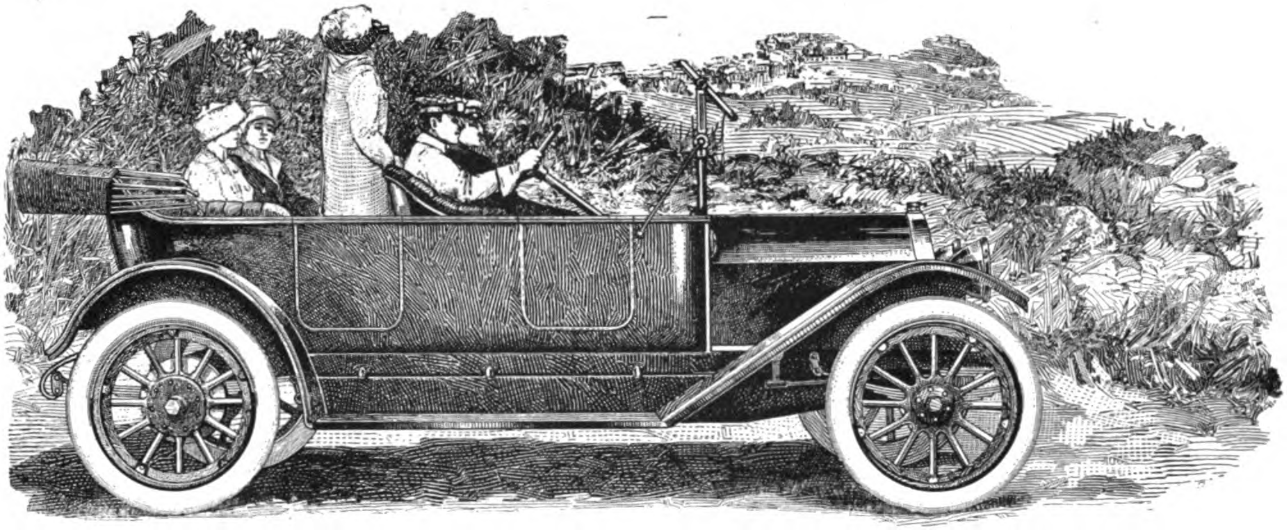

Fig. 1—Touring body fitted to the 1913 chassis brought out by the Great Western Company

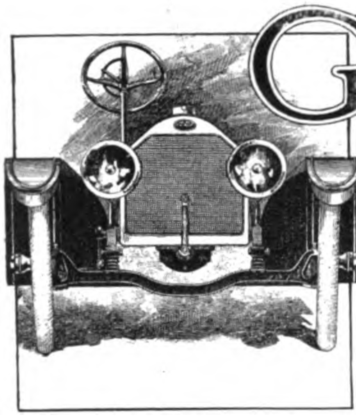

Fig. 2—Front view of Great Western

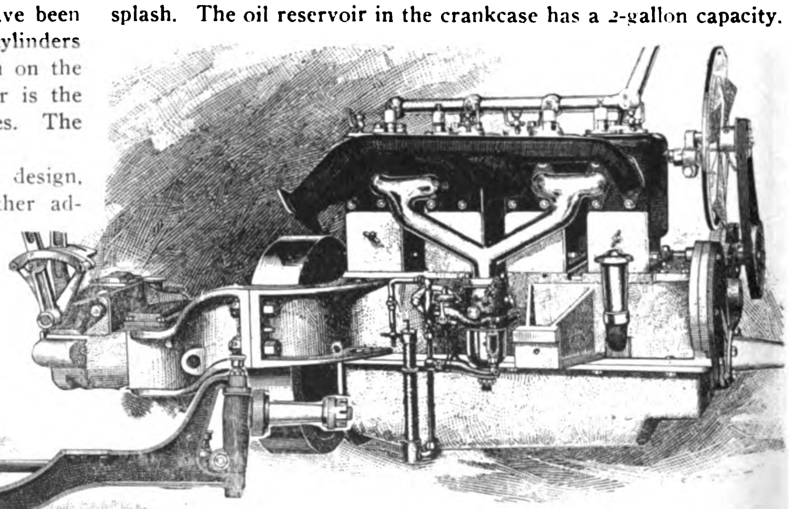
GREAT WESTERN cars for the season of 1913 will consist of four body types, the chassis for all being identical. It will be known as the 40, the same name which has distinguished it during the past two seasons. One radical change marks the introduction of the new cars to the market for the coming year: the Great Western of next year will have an L-head motor. In previous years the inlet valves have been in the top of the cylinders and the exhaust valves on the sides; they are now both on the right side of the motor. Another change in the motor is the lengthening of the stroke to 5 1-2 inches from 5 inches. The bore, however, remains unchanged, being 4 1-2 inches.

The change of stroke did not necessitate a change in design, but besides the advantage of covering the valves another advantage has been taken of the change in the operating mechanism; that is, to use roller valve followers, a step which will tend towards silence. The stems of the valves are of nickel steel, to keep wear at a minimum; while the heads of the valves are of grey cylinder iron. The two parts of the valves are welded electrically.

The Great Western power plant is of unit type. Each of the four cylinders is cast separately. The pistons are of grey iron and have convex heads. Four eccentric rings are on each piston. With the separately cast cylinders plenty of room is left for five generously dimensioned crankshaft bearings, a feature which has characterized the Great Western product of former years. The main bearing surface totals up to 15 11-16 inches. The crankshaft is slightly offset and has its bearing provided with the die-cast babbitt. The camshaft is a solid drop forging. Accessibility of the crankshaft and camshaft bearings has been taken into account by placing hand-hole covers in the lower part of the crankcase just above the oil reservoir, which is located in the bottom of this casting.

The lubrication of the motor is by circulating constant-level splash. The oil reservoir in the crankcase has a 2-gallon capacity.



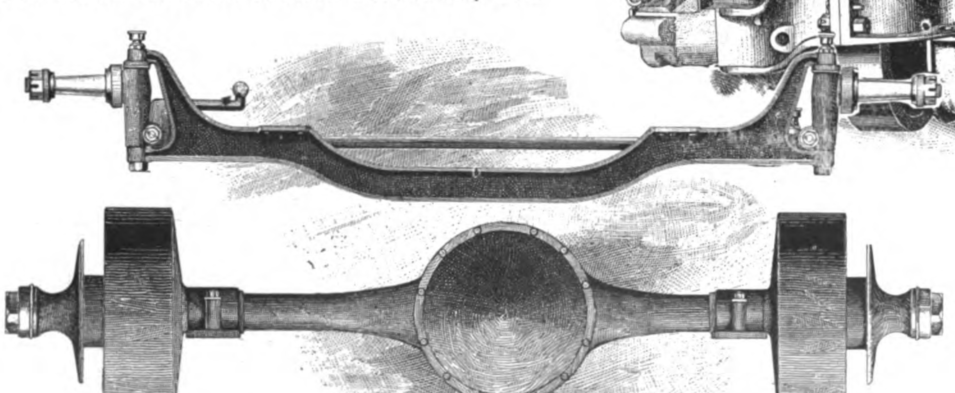


Fig. 3—Front and rear axles with steering connections

Fig. 4—Right or intake side of motor; note unit construction

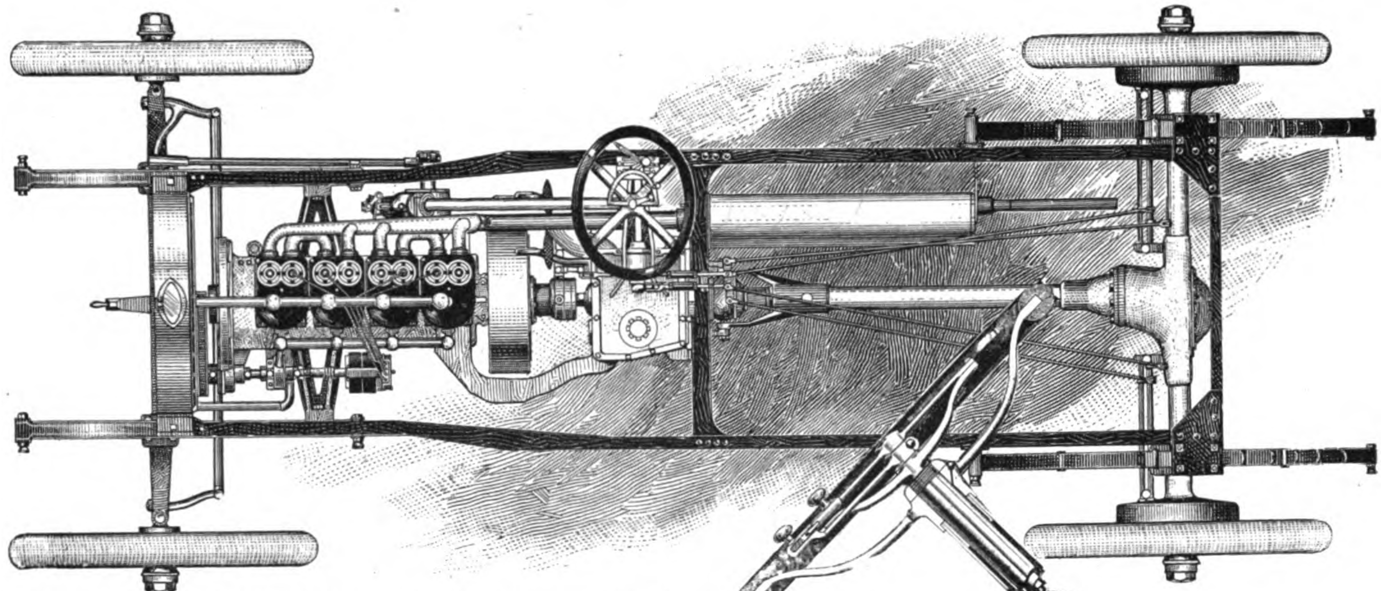

Fig. 5—Plan view of Great Western chassis, showing suspension of motor and drive

A plunger pump driven by one of the cams on the camshaft lifts the oil to the splash troughs in the upper part of the crank-case, where the lower ends of the connecting rods splash into it and throw the oil up into the cylinders. The oil pump is of such capacity that it refills the troughs faster than the oil is taken by the scoops, and as a result there is always an over-flow which finds its way back into the lower part of the crank-case again. After passing through a screen it reaches the pump and is again circulated through the motor.

The cooling, carburetion and ignition systems are all the same as the 1912 model. The water is circulated by means of a centrifugal pump located on the same shaft as the magneto through aluminum pipes to the water jackets and thence to a honeycomb radiator which is hung on the frame by brackets which are not in contact with the radiating surface. A Schebler model L carbureter is employed, while the ignition apparatus is of the Remy dual type with concealed coil and dash kick switch with lock.

The clutch is of the cone type. A change since the 1912 model has been made here in that the angle or the cone has been decreased so that engagement will be more easy and the action will be more gentle. The cone is faced with copper-woven Raybestos and there are six flat springs beneath the facing for easy engagement.

A three-speed gearset is used which runs on a double row of New Departure ball bearings. Ball universal joints are used in the propeller shaft, which is enclosed in a torque tube which connects the gearbox and the differential housing. A floating axle completes the rear system. Hyatt roller bearings are used in the differential and New Departure balls are in the axle. The springs are semi-elliptic front and three-quarter elliptic rear, 40 and 47 inches in length respectively. Double internal brakes are used on the 12-inch drums and equalizers are fitted on the brake rods. Instead of a 114-inch wheelbase, as for 1912, a 4-inch increase has been made. It is now 118 inches. As seen in Fig. 6, the steering gear is of the worm and gear type. Right control and drive has been retained.

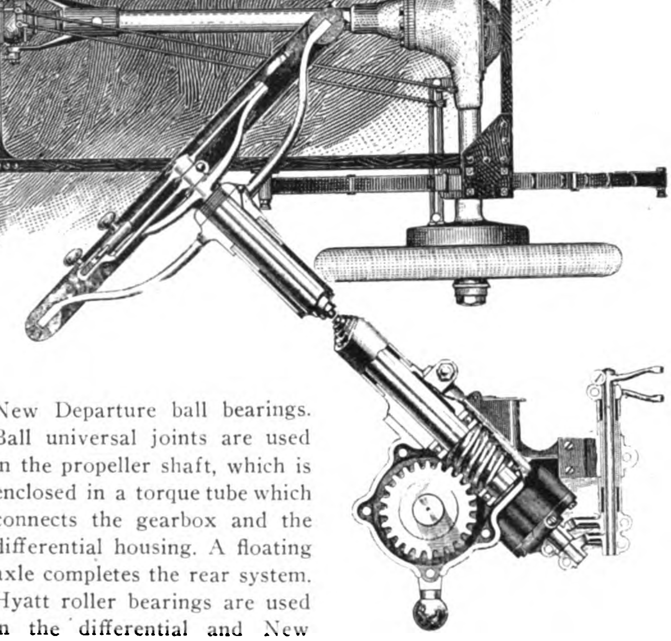

Fig. 6—Worm and gear steering mechanism

The bodies are made of a combination of steel and wood and are upholstered in hand-buffed leather. The five-passenger ton-neau is 45 inches wide. It has a small compartment between the two front seats for memoranda and the door hinges are con-cealed, giving a thoroughly up-to-date construction. The two-passenger roadster has a luggage compartment back of the seats and the four-passenger car has a removable tonneau.

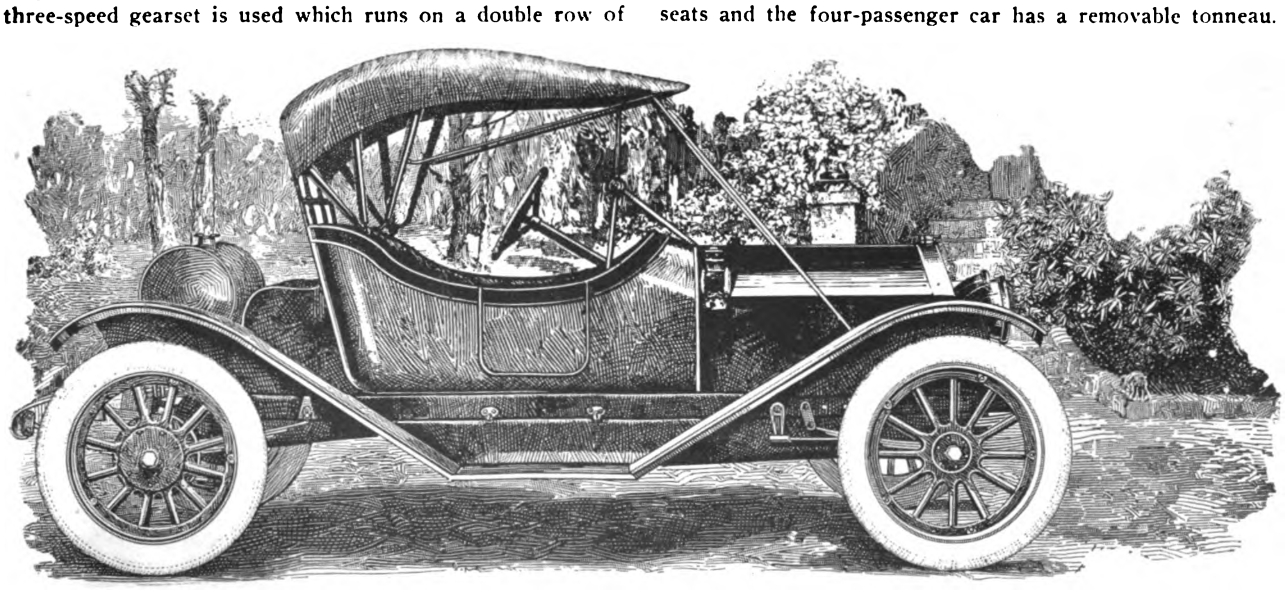

Fig. 7—Great Western Roadster fitted on the standard 1913 chassis

Four Stoddard-Dayton Models for 1913

THERE will be four Stoddard-Dayton models on the market for 1913. One of these will have a Knight motor; another, the valve-in-head plant which has distinguished the Stoddard line for 8 years, while the remaining two will embody motors of the en bloc type. The Knight motor is rated at 70 horsepower. It has six cylinders and will be placed in a chassis having left drive and center control, the same as was employed this year. The valve-in-head motor is rated by the manufacturers at 48 horsepower. All types of bodies are fitted to this model chassis, and right drive and control is used. The two en bloc motors are rated at 38 and 30 horsepower respectively. All standard types of body will be fitted to the 38, while the 30 equipment is limited to touring and compartment roadster bodies. Wire wheels are among the options for the six.

All the changes for next year are of a minor nature. Perhaps the most important change is the redesigning of the steering gear in the Knight car. This is now mounted on roller bearings and is of the worm and sector type W and S, Fig. 3. The shape of the front axle has also been changed, it now having but a single drop in place of the double drop of the 1912 cars. The cellular type of radiator has been retained, but in order to secure greater cooling efficiency it has been enlarged. The wheel hub bearings have also been made larger.

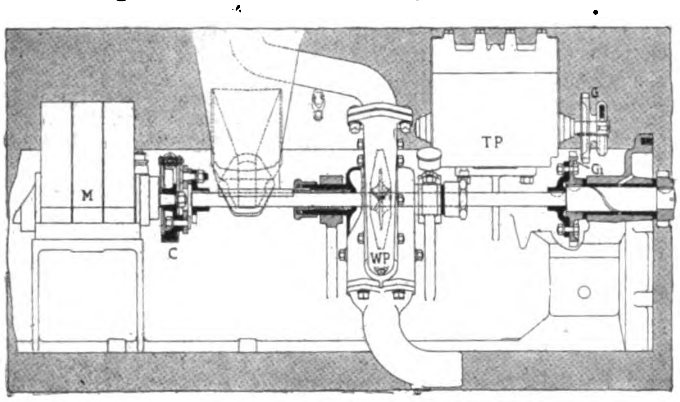

Fig. 1—Magneto and water pump shaft with tire pump on 1913 Stoddard

Valve-in-the-Head Type Will Be Continued in One Model; Two Others of Block Motor Design

The changes in the 48, 38 and 30 are negligible, being very slight and consisting only of sliding front seats which permit of adjustment for any leg-length in the case of the 48. On all the poppet-valve models the bodies are mounted upon rubber blocks to prevent squeaking and to eliminate vibration to a large extent. In fact, all through the Stoddard line the 1913 cars are distinguished more by alternations in body shapes and in added body comfort than by mechanical changes. The bodies are all longer, and in the touring style of the Stoddard-Knight two extra tonneau seats are arranged so that they can be folded into the backs of the front seats and this be out of sight when they are not required. The body presents a straight-line appearance, and the side lamps are fitted in the center of dash ventilators.

The Stoddard-Knight motor has a bore of 4 1-2 inches and a stroke of 5 1-2 inches, giving a stroke-bore ratio of 1.22. The cylinders are cast in two groups of three, the casting being so arranged as to provide for a seven-bearing crankshaft. The motor throughout is of the conventional Knight type, the two sleeves being driven by eccentrics from a longitudinal shaft which is enclosed in the crankcase and driven by a silent chain.

Splash Lubrication Retained

Lubrication of the motor is by self-contained splash with movable troughs. All six troughs are hinged to a single shaft and by a system of linkage inter-connected to the throttle. When the throttle is opened the troughs are automatically raised about their respective hinges allowing the scoops on the bottoms of the connecting rods to plunge to a greater depth into the oil contained in the troughs and to throw more up into the cylinders and over the sleeves for this reason. The sleeve valves are grooved circularly on their outside surfaces for the purpose of distributing the oil thrown upon them by the splash, while to still further aid in this purpose the grooves are supplemented with small holes. An oil pump keeps the troughs constantly full and overflowing, the surplus oil draining back to the reservoir in the lower part of the crankcase whence it is again circulated through the system. In this system the aim has been to follow the practice of keeping the amount of oil supplied in exact proportion to the work done by the motor, this plan making for greater economy and efficiency.

While 916 feet per minute piston speed is reached at 1,000 revolutions per minute, the stroke of each sleeve valve is 1 1-8 inches and at 1,000 revolutions the linear speed of the sleeve is 93.7 feet per minute. The slow movement of the sleeves is relied upon to a great extent

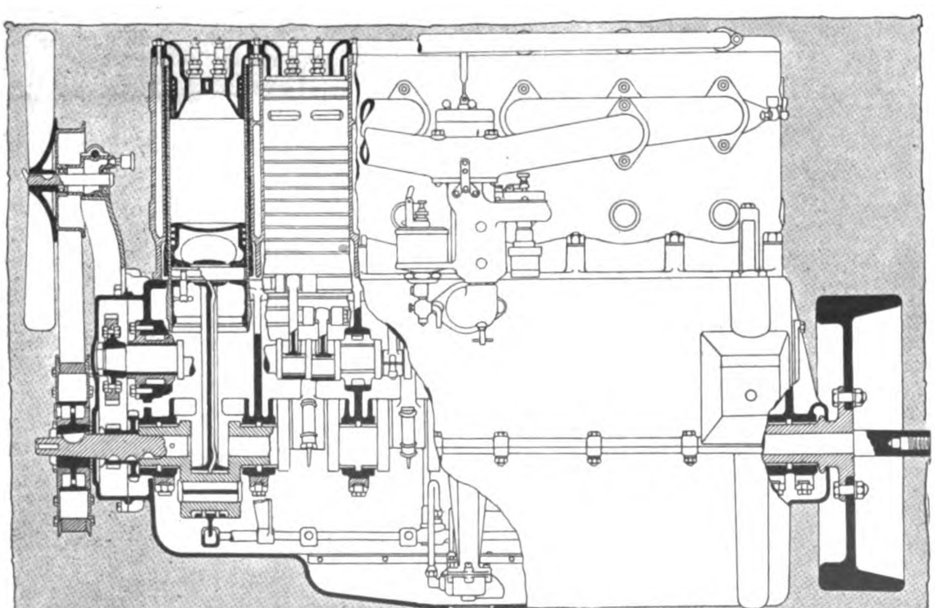

Fig. 2—Partial section of the six-cylinder Stoddard-Knight motor

Knight Sleeve-Valve Type Will Be Leader

Most Important Change is the Re-Designing of the Steering Gear—Wire Wheels Among Options

in aiding the lubrication by distributing the oil between the sleeves themselves and between the sleeves and cylinder wall.

The same ignition system which has been used on the Stoddard-Knight since its inception will be seen on the 1913 cars. It is a high-tension system acting simultaneously through two sets of spark-plugs and operated from one switch and coil on either magneto or battery. A starting vibrator is fitted to the coil which gives sparks all through the firing stroke but which does not fire the charge until the starting button has been pressed. On the magneto shaft is the tire pump, T P, and the water pump, W P, Fig. 1.

Other features of the car are the leather-faced aluminum clutch which has in addition to the leather facing a number of flat springs; the three-speed selective gearset composed of chrome nickel steel running in oil; single universal joint on the forward end of inclosed propeller shaft; bevel type of differential in floating rear axle, and two sets of 2 1-2 by 16-inch brakes. The spring suspension is semi-elliptic front and three-quarter elliptic rear; 2 1-2-inch leaves are used in the spring, giving a broad but shallow construction. The wheelbase is 133 inches and the tread the standard 56 inches.

Valve-in-Head Motor Continued

The equipment is a little more complete than ever before, consisting of best quality mohair top, top boot, storm curtains, windshield, seat covers, electric horn, trunk rack, speedometer, shock absorbers, demountable rims, aluminum running-board tool boxes, robe rail, foot rest, tire holders, tire irons, tire repair kit, a complete set of tools and extra demountable rim.

The 48-horsepower valve-in-head motor has been gradually developed by the Stoddard concern for the past 8 years, and the 1913 announcement shows no changes in the details of its construction. The bore of this motor is 4 3-4 inches and the stroke 5 inches. The four cylinders are cast in pairs, with the valve operation, as the name suggests, entirely in the head of the motor. The valves open inward into the combustion chamber and are actuated by rocker arms which reach across the tops of the cylinders. This motor has been installed in a chassis with a wheelbase of 122 1-2 inches. The two other motors are distinguished by having their four cylinders cast en bloc. They are of the L-head type and are rated at 38 and 30 horsepower respectively. The bore of the larger motor is 4 inches and the stroke 4 1-2 inches and of the 30, 3 3-4 inches and 5 1-8 inches. The wheelbase of the 38 chassis is 114 inches and that of the 30, 106 inches, the tread being standard at 56 inches.

The chassis details of these cars are practically identical. Leather-faced cone clutches with flat springs beneath the surface are used on all types. Ball bearing thrusts are used to destroy any harmful effects resulting from an end thrust on the crankshaft while the motor is running. The gearset on all these cars is of the three-speed selective type, the metal used in the construction of the gears and shafts being in all respects the same as that employed in the Knight car. A different feature, however, in this car is that drive and control are both right side.

A floating rear axle is used as in the Knight model, while the suspension is also the same with semi-elliptic front and three-quarter elliptic rear springs. The equipment is made as complete as can be desired for the 1913 cars, consisting of quick-detachable, demountable rims, mohair top and top boot, storm curtains, windshield, shock absorbers, tire irons, robe rail, foot rail, tool boxes, gas tank, gas headlights, oil side and tail lights and horn.

1913 Pierce-Arrow

Company's Line Will Include Three Models, All of the Six-Cylinder Type—Mechanical Changes Numerous

Gravity Lubrication Succeeded by Force-Feed—New Double-Jet Carbureter on All Models

FOR next year the Pierce-Arrow line of three models will be continued, all being six-cylinder types much altered from the 1912 models. A careful analysis of these three models shows that more mechanical changes have been made for next season than have been made for several years past. The changes made are typical of the three models, so that there is a standardization of design of parts running through them all. These changes, while not affecting the general design or appearance of the parts, are nevertheless important. The motor has been fitted with a pressure-feed oil system to all of the crankshaft and connecting-rod bearings, thus doing away with the gravity tank above the cylinders; a two-jet carbureter has been fitted; a compressed-air starting system has been installed, supplemented by a gasoline priming equipment as used this year; a generator to furnish electric current for the lights and also to charge the storage battery has been fitted; a new four-cylinder air pump has been installed on the gearbox for air pressure on the starting system, and also for tire inflation; there is a new fan belt adjustment; the cone clutch is now leather-faced with cork inserts instead of with German bronze; the gearbox is located farther to the rear, and a splined mainshaft is used; the propeller shaft is a tubing of large diameter instead of a solid bar; the rear axle has been generally altered, making the drive shafts removable, using stuffing boxes to prevent oil leakage and fitting larger bearings; the Pierce-Arrow demountable rim is standard; bodies are generally 2 inches lower; wheelbases are 7.5 inches longer on the seven-passenger types, giving greater space between the dash and driver's seat, and also in the tonneau; sheet aluminum takes the place of cast aluminum in open car bodies, the cast product being continued in the closed types; a new muffler without cut-out has been fitted; there has been a general improvement in the accessibility of parts, some examples being the location of the gearbox 4.5 inches farther to the rear to permit of clutch removal without interfering with the gearbox, mounting the tire pump on the forward end of the gearbox, fitting the double universal between the clutch and gearbox and making drain and test cocks on the motor oiling system more accessible.

The horsepower has been little changed except in what is known this year as model 36, but which has been changed to 38-C for next season. In this the cylinders have been increased from 4 by 5 1-8 inches to 4 by 5.5 inches, with larger valves and larger diameter crankshaft. The motors in the other two models remain unaltered, but their model numbers have been changed by the addition of a letter and now are 66-B, 48-B, and 38-C. In addition, the company is marketing a 48-D model, which is practically the 48 of this year with a Disco self-starter, the Adlake electric lighting system and the 1913 equipment added.

The motor sizes, horsepower, crankshaft speed, and piston displacement of the various models are as follows:

Model	Bore	Stroke	Horse power	Piston Dis.
66-A	5	7	66	825
48-B	4.5	5.5	48	525
48-D	4.5	5.5	48	525
38-C	4	5.5	38	339

While this table shows the factory horsepower ratings, the dynamometer tests show ratings much in advance of these. Model 66-A dynamometer test is 76 per cent. higher than S.A.E.; 48-B is 60 per cent. higher, and 38-C, 47 per cent. higher. The maximum crankshaft speed of 66-A is 1,700 revolutions per minute, and of the other models, all having the same stroke, it is 1,800 revolutions per minute. These speeds give piston speed in feet per minute as follows: 66-A, 1,966; 48-B and 38-C, 1,568 feet.

Changes Are Mostly Mechanical

Externally the 1913 motor bears a strong resemblance to that of this year barring the elimination of the gravity oil tank and the extra piping occasioned by the compressed air starter. Cylinders are made in twin castings with opposite valves and exposed tappets and valve springs. On the right side are the carbureter and magneto, the latter on the forward motor arm; on the left are four units: waterpump, oilpump, starter distributer and Westinghouse generator for lighting and battery charging. Leather disk couplings are used in the magneto, water pump and generator shafts. The disk on the magneto shaft is 4 inches in diameter and 1-4 inch thick and in the water pump shaft 3 inches in diameter and of the same thickness. The seven-bearing crankshaft is continued. The weight of connecting rods and other reciprocating parts is reduced, a connecting rod with its bushings in the 48-B weighing 4 pounds 4 ounces.

The most important change is in the lubricating system. This company was a pioneer in the non-splash circulating system, using as it did a crankcase gear pump to elevate the oil into a large gravity tank above the cylinders. For next year this gravity system has been eliminated and now the oil pump feeds direct to the crankshaft bearings, to the lower connecting rod bearings and to the upper connecting rod bearings or wristpin bearings, as they are frequently designated. The oil pump OP, Fig. 3, delivers through a duct L to filter L1 and thence to a distributer pipe L2 lying along the top of the crankcase. This distributer delivers through a branch 1 to the timing gear, through a branch 2 to the front crankshaft bearing, through a branch 3 to the middle crankshaft bearing, through a branch 4 to the rear crankshaft bearing, and through a continuation 5 to the pressure gauge on the dash. The pump gives a pressure of 20 pounds to all parts. Each connecting rod is fitted with a small copper tube which leads the oil to the hollow wristpin. The crankshaft is liberally drilled so that branch No. 2 supplies the wristpins for cylinders 1 and 2 and also the bearing B2. Branch No. 3 supplies oil to bearings B3 and B4 as well as to the connecting rods for the middle cylinders. Branch No. 4 supplies for crankshaft bearings B6 and B7 and also for the connecting rods for the two rear cylinders. While there are three oil feeds, namely, branches 2, 3 and 4, to three of the crankshaft bearings, it has been demonstrated that one branch is sufficient to furnish oil for all of the crankshaft bearings and the six connecting-rod bearings, this being due to the continuous oilway from end to end of the crankshaft and the pressure of 20 pounds generated by the pump. A double precaution has been taken in the matter of screening the oil between successive circuits of the motor. There are two strainers, S1 surrounding the suction pipe through which the pump draws its supply and SL in the discharge pipe. Both can be readily cleaned, that on the suction side of the pump by removing a plug in the face of the crankcase and the strainer SL by the hinged cap of the chamber L1 in which it is located. Heretofore the Pierce company has used baffle plates in the open ends of the cylinders to prevent an excess of oil being splashed, which might result in carbon deposits; but for 1913 these baffles will not be used, the reason being that with a new pressure oiling system delivering oil up the connecting rods there will not be that amount of oil thrown off the crankpins, and so an excess will not reach the cylinders.

Two commendable improvements in the field of accessibility are noticed in the carrying of the shaft for the drain cock up to the top of the crankcase at H1 and also that for the oil level test cock up to the point H2, making it possible to open each of these without having to reach down among the motor parts. The oil pump is external and is removable by means of the jaw coupling J. Its shaft carries on its upper end the air distributer.

Double-Jet Carbureter Adopted

A new carbureter is used on all models. It is a double-jet type, the first time one of this type has been used by the company. The entire mixing chamber is water-jacketed and the water jacketing extends twice as high as formerly. The two nozzles N and N1, Fig. 4, are located respectively in the center of the concentric float and in the auxiliary air passage. Both are

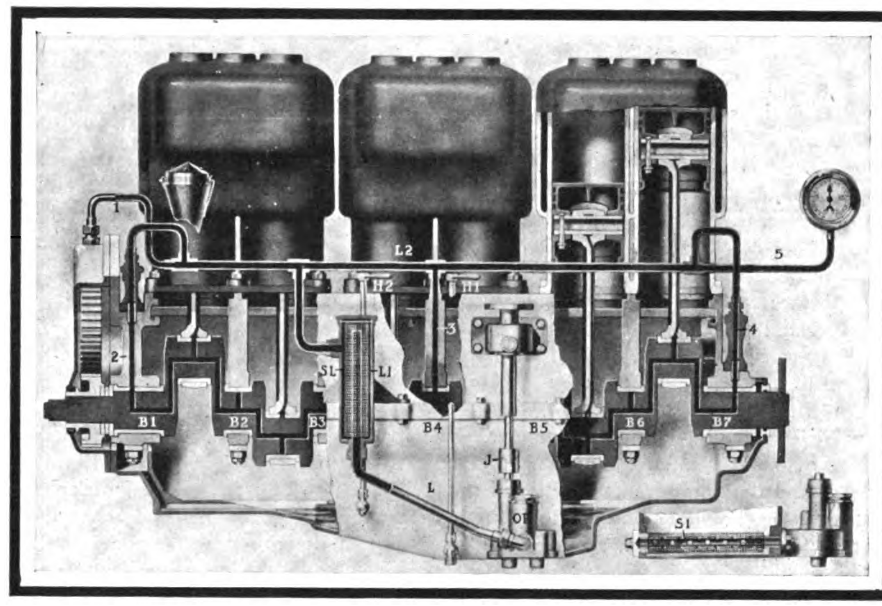

Fig. 5—Force-feed oiling system of Pierce motor, showing bored crankshaft and other oil leads

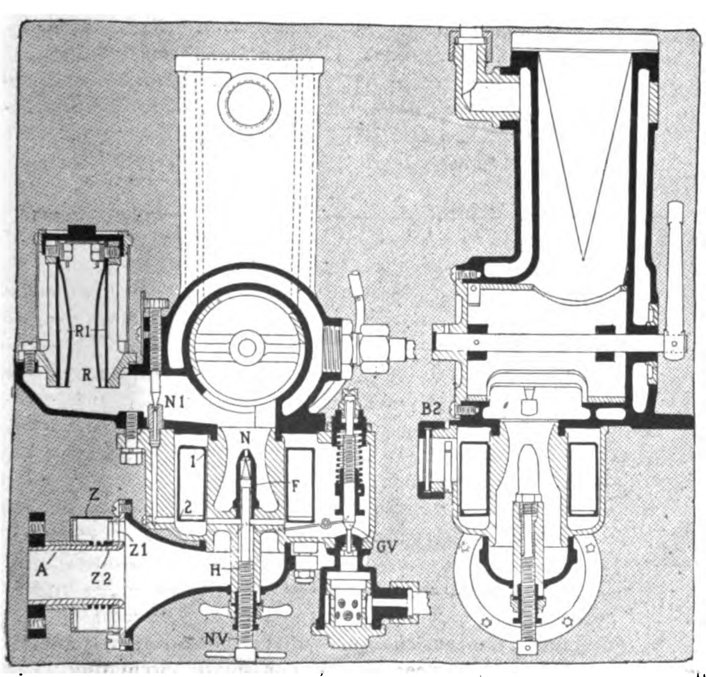

Fig. 6—Double concentric jet carbureter used on Pierce motors

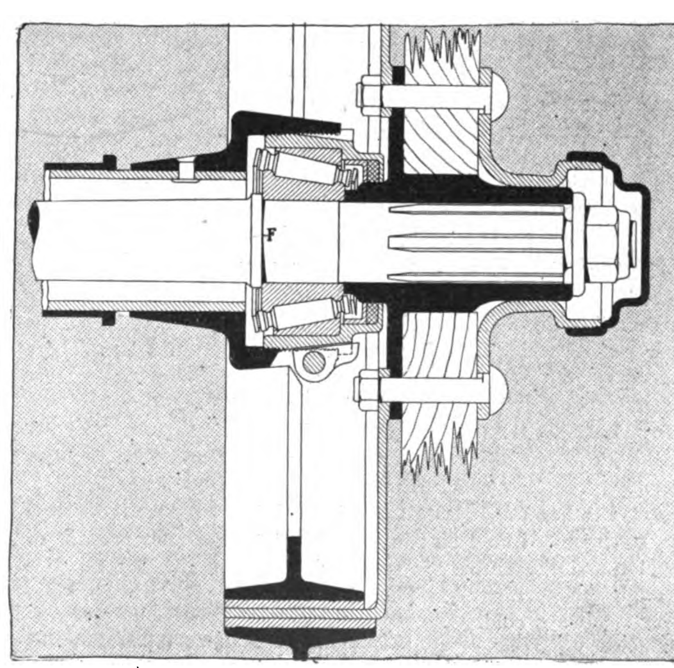

Fig. 7—Section of Pierce rear wheel, showing roller-carried hub

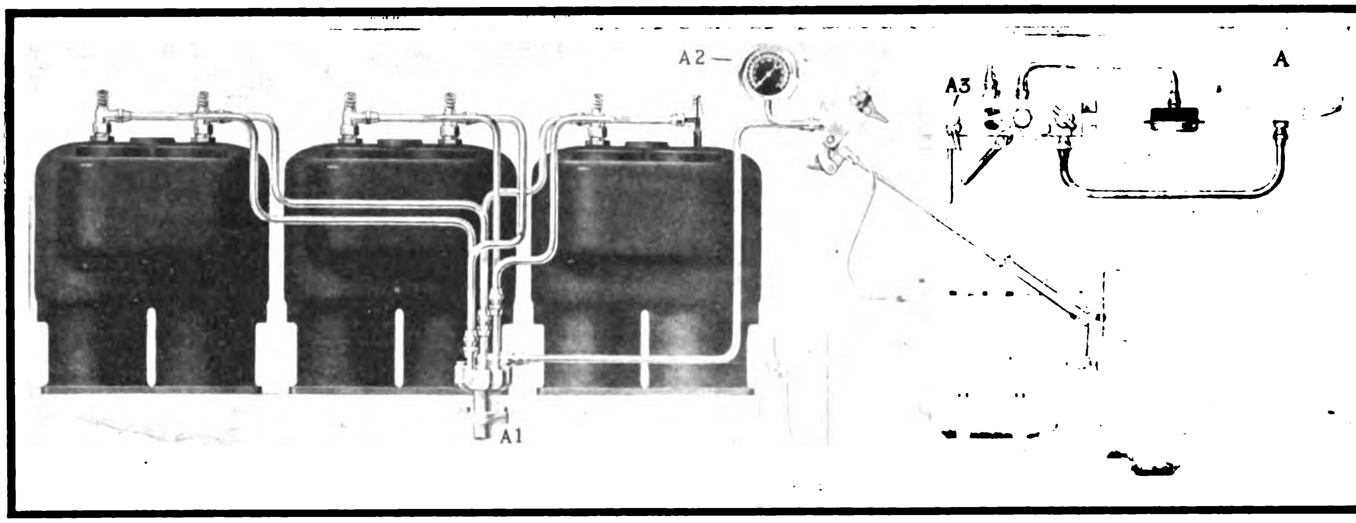

Fig. 3—Schematic view of self-starter and location of pump, air tank and distributer

controlled by hand-adjusted needle valves and are so positioned that the auxiliary nozzle does not come into use until a speed of 800 revolutions per minute is obtained and the auxiliary air valve has opened. Using the two nozzles gives a better carbureter performance on low-speed work and also on high-speed work, than was obtainable with the single-jet used to date. Thus there is a high general average on low, medium and high speeds due to the double-jet combination.

An admirable improvement has been made in the needle valve in the main nozzle. This valve has a 19-degree taper on its upper end and to protect this taper there is an enlarged fluted portion F serving as a guide to insure the point of the needle centering in the opening of the nozzle. There is a second protection for the coned tip by way of a shoulder H on the valve. The valve is a double-threaded diameter, the portion above the shoulder of small diameter, that beneath the shoulder of larger diameter, and the shoulder so positioned that when the valve is set tight on the shoulder the tip of the cone is in its proper closest adjustment. This protection removes the possibility of destroying the cone tip by screwing it up against the opening in the nozzle.

The auxiliary nozzle is a similar cone-tipped, hand-adjusted needle valve. The operation of this nozzle is closely connected with the auxiliary air valve, which has not been changed. This valve consists of two sets of reeds or vertical leaf-shaped springs. The outer set R1 is the weaker and opens partially. For further opening the reeds bear against the inner set R, which are stiffer, thereby giving a progressive opening to the auxiliary air supply. A still further progression is obtained in that one of the reeds R1 is weaker than the other, thereby opening slightly in advance. This is also true of the two reeds R.

Not Affected by Weather Changes

The main air system can be regulated for hot and cold weather. To the pipe A a tube from the muffler pipe connects. Surrounding this is an annular space formed by a housing Z, the inner end of which has a series of circular openings Z1. There is a corresponding circle of openings in the carbureter horn at this point so that by seizing the housing Z by hand and pulling outward against the tension of the spring Z2 the two sets of holes can be locked in different degrees of register and thus regulate a supply of cool air which enters through openings in the housing. In hot weather the holes Z1 are in complete register, admitting the maximum of cool air; in cold weather the holes are out of register and the entire air supply taken from the hot air pipe through the opening A. The air supply through the auxiliary valve is always cold.

The gasoline system in the carbureter remains much as heretofore, but the controlling valve has been re-designed. It has a beveled seat GV with a vertical small-diameter guide projecting downward from it. This seat rests in a corresponding bevel in the casting. Both valve and seat are ground with pumice stone. The valve is of meteor metal, which is largely nickel, much harder than brass, thus being proof against cutting or wearing. To show the gasoline level a bull's eye BZ is placed in the side of the float chamber and in it is a vertical gauge rod on which the proper level of gasoline is indicated. The float is a hollow brass piece soldered at diagonal corners 1 and 2.

Self-Starter on All Models

The company is using for the first time a compressed air-self-starter on all three models, the air pressure coming from the four-cylinder air pump located on the forward end of the countershaft of the gearset and so arranged as to be thrown into operation by pedal at the driver's will. The air from this pump is delivered into the air reservoir A, Fig. 6, where it is held at a pressure of 200 pounds. From this tank it is led to the air distributer A1 located on the left side of the motor between the water pump and lighting dynamo and driven by a continuation of the vertical oil pump shaft. From the air distributing housing piping leads to special connections in the cylinder heads, each of these containing a check valve. The control of the apparatus is from the floor board, where there is also located a gauge A2 to show the air pressure in the tank. A3 shows the control for cutting the air pump in or out of service, and to its left are the other control parts, this illustration being a top view of the control parts. The air distributer is a rotating disk having an oblong circumferential slot. The air supply enters the cover of the distributer centrally and the air delivery pipes enter the distributer case beneath the disk. As the disk rotates its slot

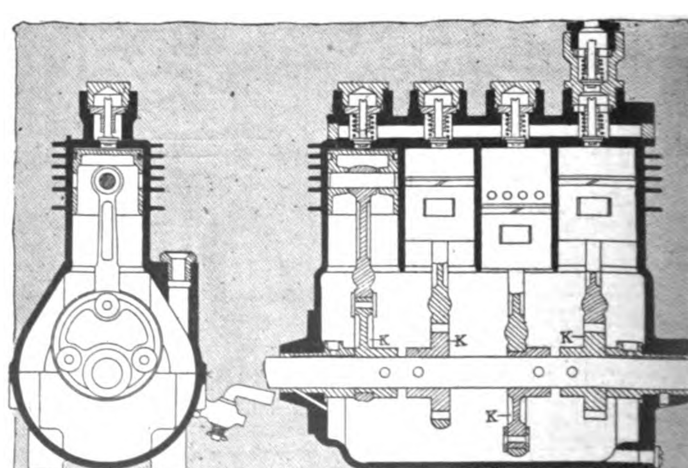

Fig. 4—Cross and longitudial section of Pierce motor

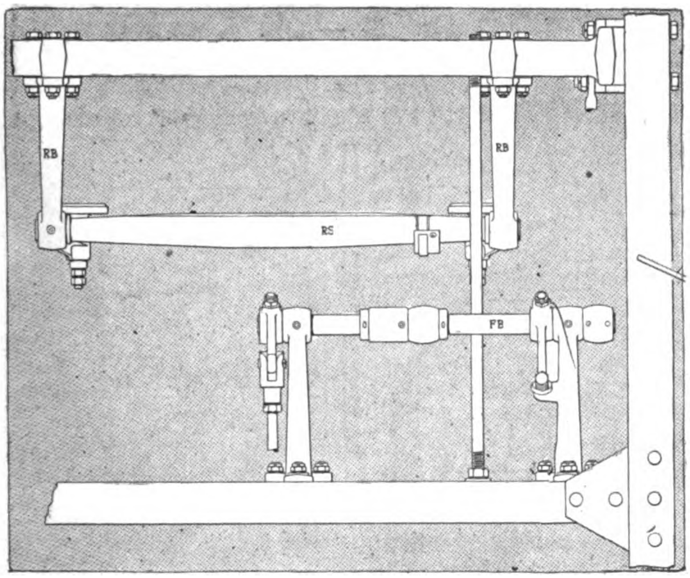

Fig. 8—Method of supporting the clutch rocker shaft on the frame

registers in firing order with the different cylinders delivering the air pressure to the one on suction stroke and to the others in sequence, so as to give a continuous turning movement to the crankshaft.

Tires Are Inflated by Power

A new design of power air pump is used for tire inflation and also to furnish the 200 pounds air pressure needed for the self-starting reservoir. The pump is a Pierce product and is a four-cylinder air-cooled design located at the forward end of the countershaft of the gearset and controlled by clutch mechanism with operating parts on the dash so that the pump only operates when the driver wants it to. The cylinders, of 1 7-16-inch bore and 1 1-4-inch stroke, are formed in one casting which is integral with the upper half of the crankcase. The crankshaft is a 5-8-inch bar on which are mounted the four eccentrics K, Fig. 7, which take the connecting rods. The pistons carry one eccentric ring with diagonal split at the upper end and have large rectangular perforations midway of their height. In each cylinder head is an automatic discharge valve forming a connection between the pump cylinders and the collector tube in the casting head. There is a fifth automatic valve in the delivery tube to the tank reservoir, this valve being located immediately above the valve for the front cylinder.

The pump operates on the two-cycle principle, there being drilled in the cylinder walls a series of small holes at a point immediately above the piston head at the lowest point in its stroke, these holes appearing in the second cylinder in the illustration. The pump has an overall length of 10 inches and a height of 8 inches.

For tire inflation work it is recommended to take the air direct from the pump instead of from the 200-pound reservoir located on the chassis over the muffler, this being due to the possible danger of bursting tires by using the reservoir pressure. Inflating direct from the pump can be done in a 38 by 5 1-2-inch tire in 7 minutes.

Details of Clutch and Gearset

In manufacturing the pump every care has been exercised in the finish of the cylinders, pistons and rings. It operates at one-half crankshaft speed.

Fig. 9 shows the clutching mechanism at the forward end of the gearshaft. The housing G extends and to this bolts the corresponding housing on the pump. The forward end of the countershaft has a jaw clutch G1 with which is engaged a corresponding sliding clutch G2 on the pump shaft.

The four-speed gearbox, which has been a standard of Pierce construction for several years, is continued in improved form. The main shaft MS, Fig. 9, is a fluted design, having six flutes. The rear end of this shaft, where it takes the universal joint member, is also similarly fluted. Both ends of the shaft are provided with self-adjusting glands to prevent oil leakage. These consist of a packing G compressed by a small plunger backed up by spring G1. The entire stuffing box construction is contained within a cap K holding the bearing in place. Similar stuffing boxes are not used on the countershaft for the reason that there is a bearing cap K1 at the rear end which does not offer any chance for oil escaping and at the forward end of this shaft the housing G containing the air pump clutch forms an oilproof connection with the air pump housing.

A new form of interlocking device is used to prevent the engaging of two trains of gears at the same time. This is an automatic arrangement consisting of a small vertical roller R located between the two shifter rods R1 and R2. A slight groove is cut in the adjacent side of the shifter bars at this point, and the width of the roller is such that when resting in one groove the

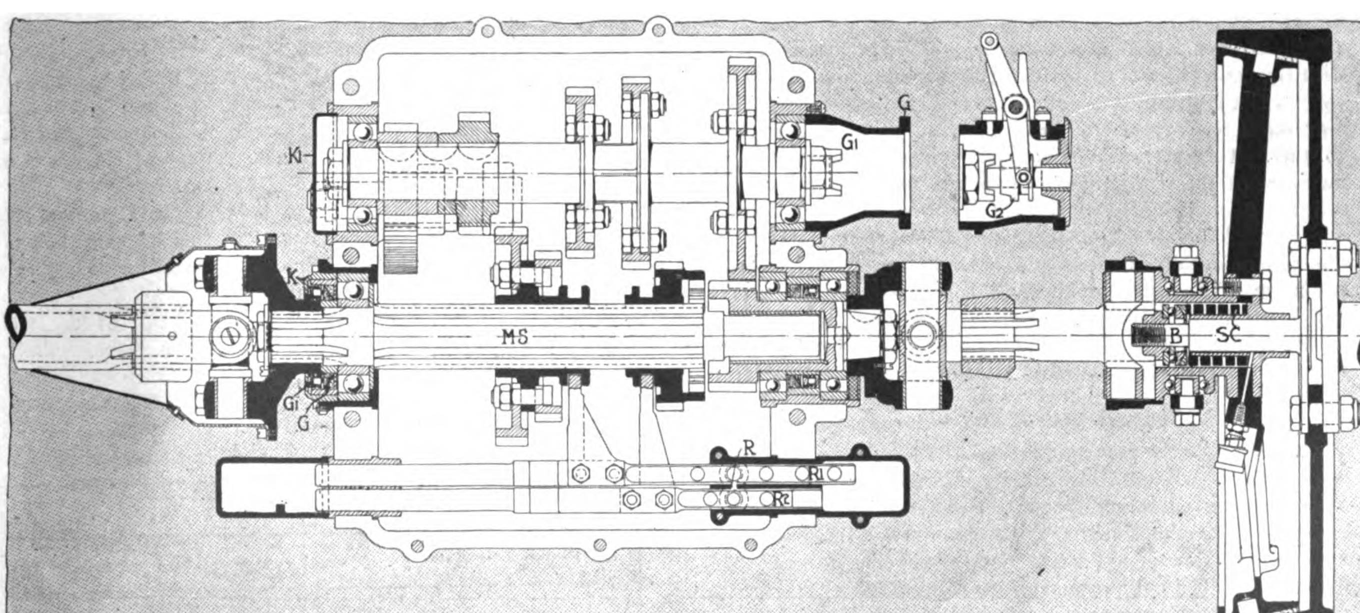

Fig. 9—Sectional view of the four-speed gearset and cone clutch. Attention is called to the arrangement which prevents simultaneous meshing of different gear trains

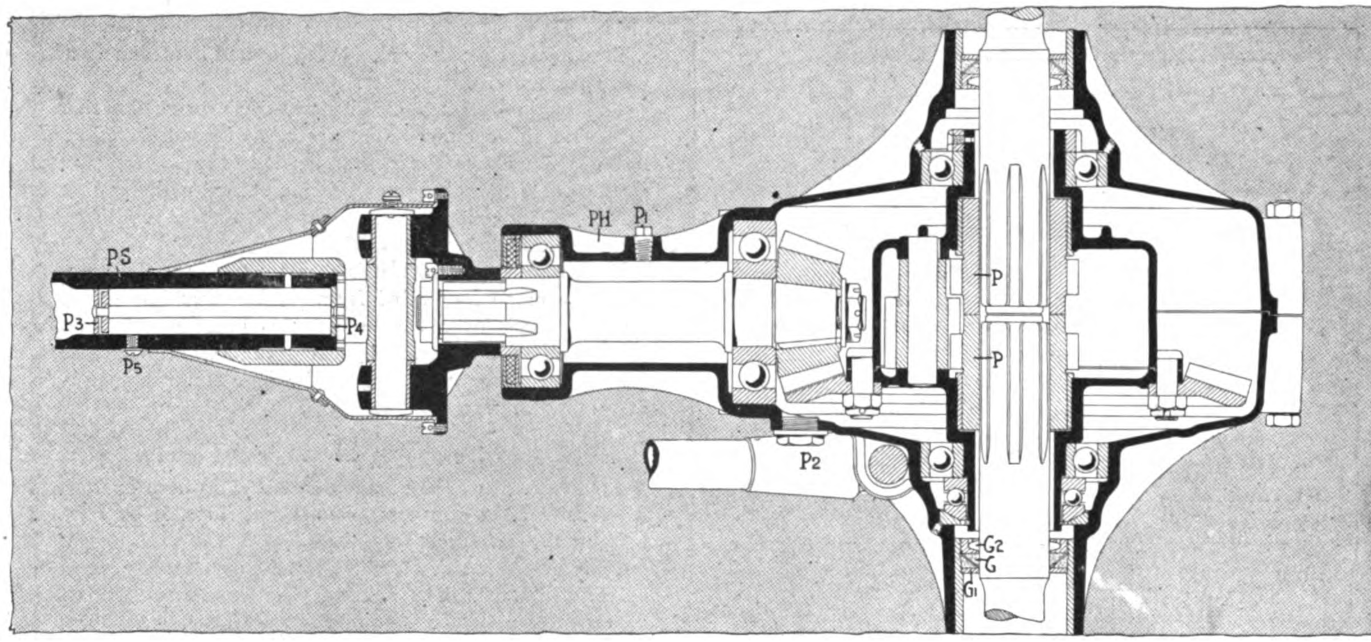

Fig. 10—Horizontal cross-section through end of propeller shaft and differential gearset

other shifter bar is free to move, but there is not sufficient room for the roller should both bars be removed at the same time. With this simple protective measure the old form of interlocking bolt and quadrant type used to insure the clutching being disengaged before gears could be shifted has been eliminated. There was a time when the company considered such protection necessary, but that time is now past.

An important clutch change has been made, in the form of using a leather facing on the cone with cork inserts. Heretofore a German bronze composition has been used. In clutch engineering the aim is to reduce weight to the minimum in the cone itself. This is done to prevent grating and grinding when shifting gears. The leather with cork inserts is lighter than the bronze facing. The clutch is a 13-degree cone angle. The engaging spring SC, Fig. 9, is entirely enclosed and its end thrust is taken by a self-centering thrust bearing B, the self-centering factor being the arc of curvature on the inner thrust plate. There is 4 1-2 inches more space between the clutch and gearbox than this year, making it possible to remove the clutch without interfering with the gearbox. This additional space permits of the use of a double universal joint at this point.

Still another clutch improvement, which is closely associated with the control parts of the car, consists in mounting the clutch rocker shaft RS, Fig. 8, on two brackets RB attached to the rear cross support of the motor, this support being an I-beam forging. This year this rocker shaft is supported on the side members of the frame, but in its new position its easy operation is insured in that should the side members of the frame warp, due to road irregularities, there is no danger of it interfering with the easy operation of the clutch. Hand in hand with this is the mounting of the foot brake shaft FB on similar brackets supported on the cross member of the frame instead of mounting it on the side members. The same object has been in view, namely, the preventing of frame strains interfering with brake operation.

Accessibility of the Rear Axle

On all models the rear axle driveshafts X, Fig. 14, may be withdrawn without dismantling the housing. Heretofore on all models excepting the 66 the differential pinions P have been keyed to the shaft, making withdrawal impossible. The new construction is a floating design, but the removal of the driveshaft calls for the removal of the road wheel together with the Timken bearing supporting the outer end of the axle. Fig. 5, shows the flange F against which the bearing rests and by means of which the end thrust is absorbed. Axle driveshafts are 1-8 inch larger in diameter and they are fluted at the inner and outer ends instead of being keyed at the inner ends and provided with taper and key at the outer end. On Model 66-A ten splines are used on either end of the shaft, whereas models 38 and 48 use six splines.

For 1913 all models will use a heavy black liquid oil for the bevel gears instead of axle grease. This has called for the introduction of packing glands at either side of the differential to prevent oil working out and getting on the brakedrums and wheels. There is a gland at each side consisting of No. 109 Crandell diagonal packing G held between a steel washer G1 resting against a shoulder in the axle sleeve, and a threaded nut G2 at the inner side. As the nut is threaded against the packing the diagonal split allows the halves to gradually slide up against each other forming a tighter joint. The use of liquid as lubricant is due to the fact claimed that with axle grease under continuous running at high speeds the grease is thrown off the pinions by centrifugal force and has not time to come back to them.

Tubular Propeller Shaft Used

The axle housing remains practitcally as heretofore and consists of bell-shaped halves to take the differential, these being steel castings, into which Shelby steel tubing, which forms the axle sleeves, is brazed and riveted in place. A new and longer pinion housing PH is used and is fitted with two Hess-Bright bearings to support the shaft. These bearings are now farther apart, and the rear one, a No. 409, is larger than in previous years, this being done to hold the bevel pinion better up to its work. Axle grease is used in this housing, being inserted through the plugs P1, while P2 serves for inserting the liquid lubricant for the differential bevel.

This illustration shows how the forward end of the pinion shaft has a six-spline ending to take the universal joint. It further shows the use of the tubular propeller shaft PS, which is new on all models. The tubular construction has been used because of lighter weight and greater strength, there being a reduction of 15 per cent. in the weight when compared with solid

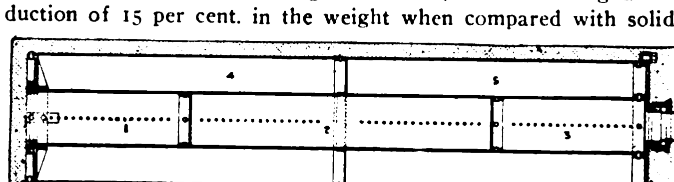

Fig. 11—Double concentric tube muffler giving silence and minimum of back pressure

shafts with increased strength. The added strength is due to the larger diameter which prevents whipping of the shaft and thereby eliminates chattering in the universal joints as well as in the gearbox. On Model 66-A the tubing is 2 1-8 inches in diameter and of 5-16 stock.

A neat method of lubricating is employed for the rear end of the shaft where it takes the sliding joint. The shaft carries six flutes or splines and within it is a packing piston, the forward end P3 being made up of a leather disk between two metal washers, while the rear end is a metal plate P4 fitted against a shoulder on the end of the shaft. Through a plug P5 the chamber between these ends is filled with lubricant which works out through the drilled holes in the shaft. In this particular the hollow propeller shaft is of special merit as it facilitates and insures adequate lubrication of the slip joint.

The Pierce engineers have recently installed a special testing machine to discover amount of backlash in the differential planetary gears. The axle is mounted in its housings and the large spur gear locks. An 18-inch crank is attached to the outer end of one driveshaft. An indicating pressure gauge is adjusted so as just to bear upon this crank. The tester seizes the end of the crank and moving to and fro discovers through the reading of the pressure the exact amount of backlash. In order to guard against backlash the six spur pinions of the gearset are carefully selected with reference to one another, and are retained in sets. If, however, when the final test is made there is too much backlash an entire new selection is made. The reason for special care in the elimination of backlash is that according to the Pierce engineers it is largely responsible for noises which are transmitted to the gearbox, and it also increases tire wear.

Muffler Reduces Back Pressure

The new muffler, Fig. 11, consists of two concentric tubes, the inner tube, 2 3-4 inches in diameter, divided longitudinally into three sections 1, 2 and 3, and the outer one, 6 1-2 inches in diameter, into two sections 4 and 5. Gases enter No. 1 division and escape through openings and expand into No. 4 division. They progress from No. 4 into No. 2, which is double the length of No. 1, and again expand into No. 5 and finally escape through No. 3 to the muffler tail pipe. Back pressure on the motor has thus been reduced to a minimum, as demonstrated by the slight differences when a cutout is used and when not used, the factory conclusion being to discontinue the cutout.

The Westinghouse generator mounted on the left rear side of the motor and driven through a continuation of the waterpump shaft runs at crankshaft speed and will generate sufficient current at 12 miles per hour to supply the lights. The generator weighs 38 pounds and is so compact as not to interfere with valve spring accessibility for the front cylinder casting. The generator discharges into an 80-ampere-hour Exide battery and supplies a lamp equipment made up of 20-candlepower headlights, 4-candlepower dash lamps, one 4-candlepower tail lamp, a 4-candlepower license lamp and a 1-candlepower gauge light on the dash. All lights take a 6-volt current. The generator is fitted with a magnetic clutch which prevents the battery discharging through the generator when idle. On open cars the amperage consumption for the entire lamp equipment is 10.5 amperes and on the enclosed and suburban types, which have dome and side-door lights, the consumption is 11.75 amperes. The wiring is all in copper tubes and the single-wire system is used, that is, the wire leads to the lamp filament and the other end of the filament is grounded. This wiring system for lights is simpler than the double-wire one and permits of a stouter bulb construction. A feature of the generator is that the current is sent through an iron resistance which regulates the voltages and thereby protects the bulbs. On the dash is a voltmeter connected across the battery. The battery in addition to furnishing light is also used for ignition in starting and in emergencies.

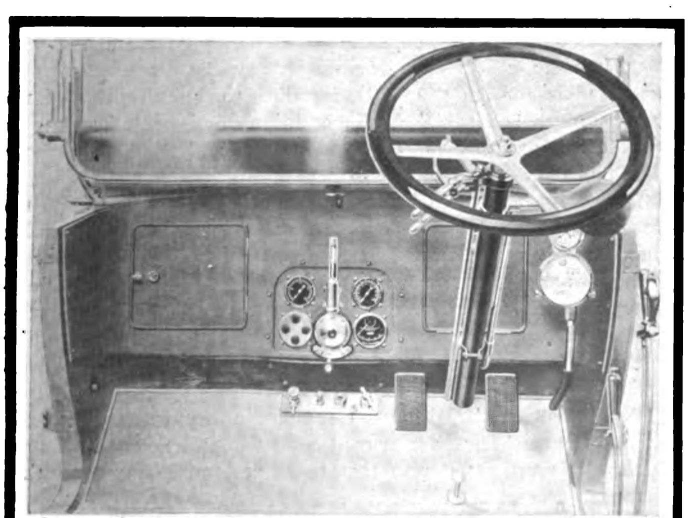

Fig. 12—The appearance of the Pierce 1913 dashboard is simple

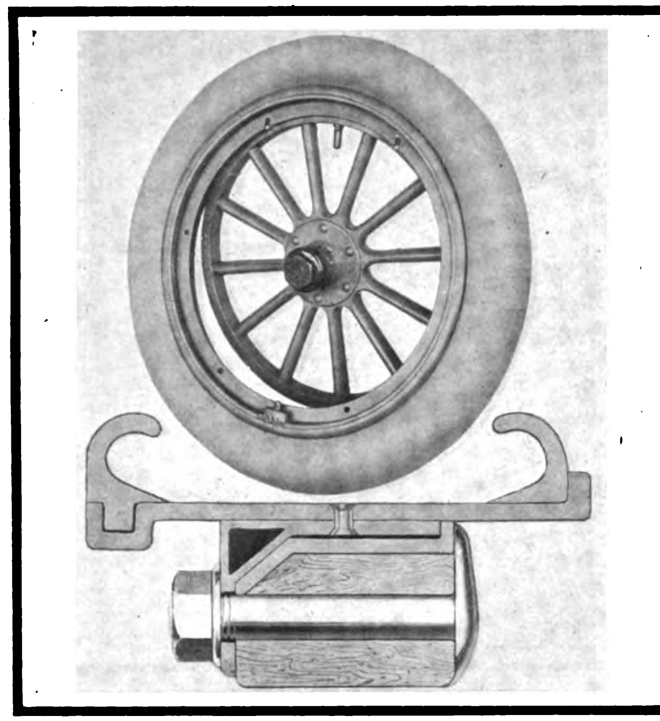

Fig. 13—Rim of Pierce-Arrow cars takes demountable or quick-detachable tires

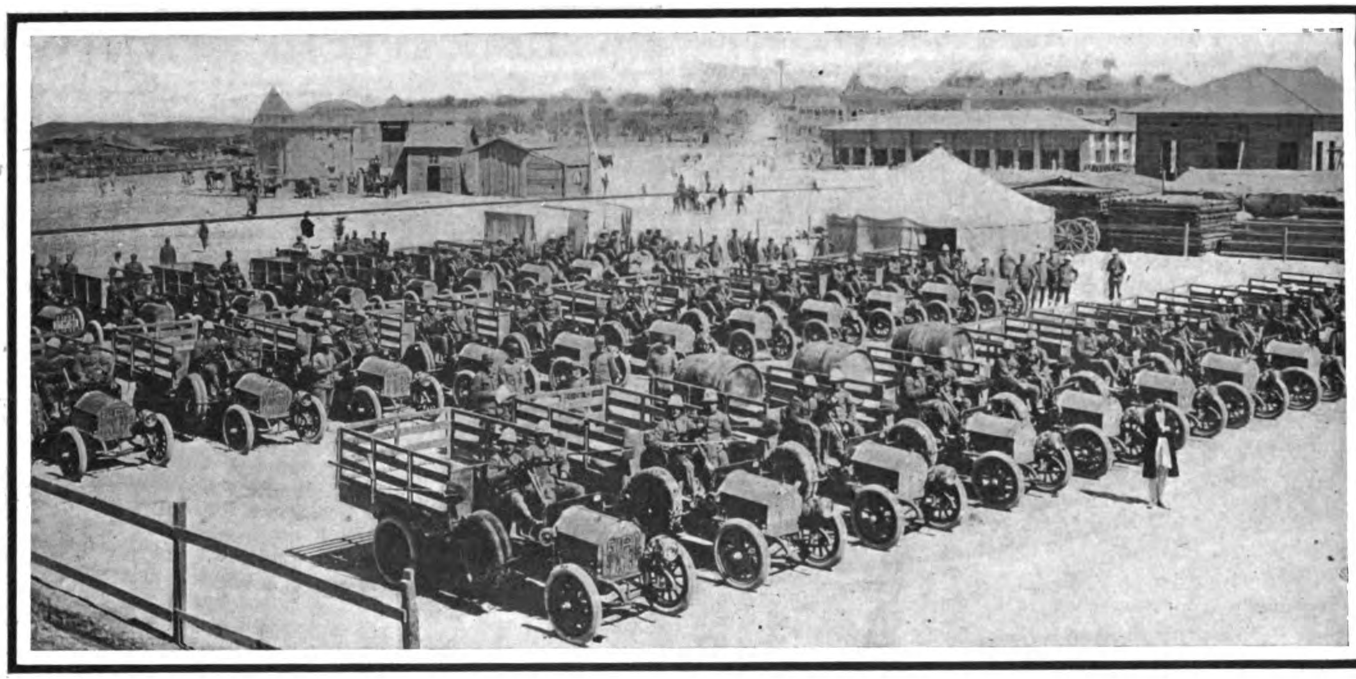
The 1913 braking system is the same as at present, consisting of internal and external sets on the rear hubs. The expanding set is faced with German bronze and the contracting set with asbestos fabric. The bronze has been used by the company for several seasons and gives 15,000 miles service without adjustment. The fabric for emergencies is used so as to have two different brake surfaces; should the metal be affected by heat, the fabric remains in working condition. Drum sizes are the same as before.

Pierce Company Has Own Rim

The company fits its own demountable rims, which will take any type of quick-detachable tires. The wood felloe is bevelled to approximately 45 degrees at one side, this bevel extending one-third distance across the felloe top. Over this is fitted a metal band which receives a corresponding band electrically welded to the inner side of the rim taking the tire. A series of six transverse bolts draws the rim's beveled surface up on the band bevel so that the transverse bolts are not called upon to carry any of the radial load. There is a radial projection on the rim bevel which is brought up tight against the outer side of the wood felloe and at the same time the rim is brought up against a shoulder on the felloe band at the inner side of the felloe. The transverse bolts are made with large, strong heads.



An encampment of motor trucks in the Tripoli war district—These trucks have all been requisitioned from their owners in Italy

Motor Trucks in Tripoli

Fleets of Home-Built Vehicles Enable Italians to Wage Effective War in Enemy's Country

Specially Equipped to Carry Water, Provisions, Baggage, Ammunition and Other Necessities

NEVER has a modern war been conducted with so little publicity as that which Italy wages against the Turks in Tripoli and Cyrenaica, those once fertile and prosperous provinces along the African coast of the Mediterranean Sea where the suzerainty of the Sultan of Turkey over the native Arabs for many years has been maintained only in name and by the religious bonds which unite all of Islam. Japan's example in successfully excluding the war correspondents from all early and real knowledge of the war movements in its recent war with Russia has, it is supposed, had much to do with the policy of silence which Italy has adopted, but still more powerful in this respect has been the desire of the Italian army and navy departments to keep all which might be learned with regard to the use of automobiles and aeronautic war equipment for themselves. From such sporadic accounts as have leaked out, it appears, however, that the passanger automobile has not so far proved itself of great utility, the war being one of slow penetration and occupation in which the rapid movement of troops has counted for so much less as the roads were mostly non-existent when the war began over a year ago and could be built and pushed forward only in the measure as the occupation proceeded and was safeguarded against the guerrilla attacks of the intrepid Arabian tribes. In the reconnoitring service aeroplanes were hit and brought down with rifle bullets whenever the pilots ventured near enough to the ground to make an intelligent croquis of the situation, but the dirigible balloons, on the other hand, being not forced to maintain themselves in the air by high speed and being able to carry a larger number of competent observers, are reported in several instances to have brought home valuable tactical information gleaned from an altitude of 6,000 feet above the territory which it was the intention to occupy next.

The transportation of materials wherewith to fortify and secure every advance gained by the infantry has in this slow conquest played an important part, and for this reason the motor truck has been much more conspicuous than the automobile of the passenger-carrying type. But the motor truck has no more been in the foreground of events than its lighter and faster kin. Its mission has been to carry the supplies from one camp already established and secured to another next in order to be prepared as a permanent fort in this campaign of forcible colonization, by which Italy hopes to keep her sons under her own jurisdiction and stem the flood of emigration to the United States. The accompanying illustration shows a division of these motor trucks, all of Italian manufacture, parked in safety and ready for their next errand of peaceful carrying of useful loads.

Foreign Markets for Motor Vehicles

Washington, D. C., Aug. 3—The fact that the motor car makers of the United States are annually making enormous strides in their invasion of the foreign markets is brought out forcibly in a monograph entitled "Foreign Markets for Motor Vehicles," just issued by the federal bureau of manufactures. This publication is a compilation of reports from American consuls stationed in every part of the globe, and is arranged with the particular end in view of aiding American manufacturers to extend their foreign sales. It describes the peculiarities of the various markets, special local conditions and prejudices to be considered, foreign competition to be met and the best methods of selling cars.

Canada is the United States' best market, the majority of the cars in use in the territory of our northern neighbor being either made entirely in the United States or made by Canadian branches or affiliations of American firms. The high-road clearance, flexibility and moderate price of the American car are steadily winning it favor in regions where highway conditions are similar to those in the United States. The market in Australia and New Zealand is already being well cultivated by American exporters, while Argentina, Brazil and Uruguay in South America, and British South Africa are named as promising fields for future sales. It is estimated also that there are more American than European cars in use in Mexico.

In the Far East, Ceylon, India, Japan, Siam, and the Straights Settlements are the most likely markets. China has little use for motor cars, as most of the roads of that country do not permit their use. The reputation of American-made cars in India suffered some years ago because some inferior cars were sent among the earlier shipments to that country, but the cars brought from the United States recently have been of such high grade as to dispel this prejudice. In the Straights Settlements the principal buyers are wealthy Chinese, who demand comfort and luxury in their cars rather than high power. As a result, low-hung, smooth running cars are the most popular, and the local trade often demands that each car be fitted in accordance with the individual taste of the owner. Right-hand drive is essential there, as in the Orient all traffic turns to the left, instead of to the right, as in the United States.

The United Kingdom has been and continues to be an excellent market for American cars, ranking next to Canada in purchases from the United States, but the sales in continental Europe have thus far not been extensive. The excellent roads of most of the European countries permit the use of a heavier, lower-hung car than is found commonly in the United States. In England, however, the low prices and complete equipment of American cars are fast increasing their popularity, while they are rapidly overcoming the prejudice against them, caused by doubt as to their durability due to the sale of many cheap, unsubstantial American-made bicycles in England some years ago. The method of American makers in putting their cars on the market fully equipped is in strong contrast with the practice of continental makers, who quote prices on the chassis only, with the body and all equipment listed as extras.

New York's Fire Rules Revised

The first revision of the rules of the New York Fire Department has been made since 1905 and a neat little manual has been issued to govern the department. There is surprisingly little mention of automobile fire apparatus, considering that such a large fraction of the fire-fighting machines installed in New York is composed of motor-driven vehicles.

Among the rules specifically directed at the automobile apparatus are the following:

In section 34 it is ordered that the company commander shall ride alongside the chauffeur. Section 75 provides for special reports as to the effect of inferior gasoline upon motors. Section 112 forbids any member of the department to ride in an automobile not the property of the department and requires all members to prevent any person not a member of the department from riding on a department automobile.

Several of the rules provide for maintaining and caring for motor apparatus, but there is nothing different in their language than in that applied to the horse-drawn engines.

The department is organized under the new rules as a military body with Commissioner Joseph Johnson as honorary colonel and Chief Kenlon as colonel commanding.

Canadians After Car Smugglers

MONTREAL, Aug. 1—Wholesale smuggling of automobiles between the United States and Canada has been going on this summer, and the Canadian customs officials have already punished several offenders, while the Canadian manufacturers are bitterly protesting against American-made cars being brought into Canada without payment of duty.

Naturally the majority of dealers in the city who represent United States firms either deny the charge or refuse to discuss it at all; but the fact remains that a special customs officer has had a busy time of it all summer working up evidence upon which seizure could be made, and at least one agent, who is interested in a Canadian make of car, admits it.

"It is simply a question of some of the United States automobile manufacturers getting even with some of the Canadian fur and clothing manufacturers who for years have sold goods to the United States visitors with the understanding that they are to

Calendar of Coming Events

What the Months Ahead Have in Store for the Automobilist—Shows, Conventions, Race Meets, Etc.

American and Foreign Fixtures of Importance Set Down in Chronological Order

Shows, Conventions, Etc.

Sept. 17-20........Denver, Col., Convention International Association of Fire Engineers.
Sept. 23-Oct. 3....New York City, Rubber Show, Grand Central Palace.
Dec. 7-22..........Paris, France, Paris Automobile Show, Grand Palais.
Jan. 4-11..........Cleveland, O., Annual Automobile Show.
Jan. 11-25, 1913...New York City, Thirteenth Annual Show, Madison Square Garden and Grand Central Palace, Automobile Board of Trade.
Jan. 20-25.........Philadelphia, Pa., Annual Automobile Show.

Nov. 8-16.........London, England, Olympia Automobile Show.
Jan. 11-22.........Brussels, Belgium, Annual Belgian Automobile Show, Centenary Palace.

be delivered into the United States without paying duy," said he.

"To deliver an automobile free of duty is a big thing, for the duty upon autos from the United States amounts to about one third of their value. Naturally leaving the question of deceiving the Government out altogether, the smuggling of automobiles is decidedly unfair to the Canadian factories."

Custom house officials decline to discuss the matter, but admit that a number of automobiles manufactured in the United States have been seized here for non-payment of duty.

The total number could not be ascertained, nor the names of the purchasers, but one customs man said "The number is very large."

It was also ascertained that while the customs people were not anxious to hold the sinners in this matter up to public opprobrium, they have, by order from headquarters in Ottawa, treated them severely, and have in each case given them the choice of losing their car or paying its equivalent in money, according to the listed price, to the Treasurer of the Dominion.

As imported cars are seldom listed under the $1,000 mark, but more often up to the $4,000 and $5,000 figure, it is easy to see that the amount of seizure money climbs up pretty fast.

As another customs official said, the smuggling of automobiles is a most difficult thing to guard against on account of the tremendous length of the border line.

A Virgin Field

TO manufacturers branching into the commercial car zone there is not any greater opportunity than that offered in the agricultural field for a gasoline tractor selling at $1,200 or $1,500 at the outside. Today the makers of agricultural tractors have been building for the $2,500 field and up, and while the demand is large it is nothing compared with that for a machine at approximately half that price. A tractor selling for a little over $1,000 has an unlimited field. Every owner of one-quarter section of land, 160 acres, and up is in the market for such a machine. They are in the market in this class because the present machine is too high-priced for their holdings.

The expansion of many agricultural tracts is so great today that motor-propelled machinery is the only solution. The people are waiting for the machine and the opportunity is offered as never before: The missionary work has already been done. For years the builders of steam engines catered to the agricultural field, but in a very limited sphere because of the excessive weight of the product. For a decade the gasoline engine maker has been exploiting this fruitful territory; and for several seasons the interest has been sufficiently great to promote annual contests for the education of the agriculturists and greatly to the benefit of the maker. There is today a wider market for the $1,000 tractor than there is for any type of pleasure car.

Improving Lubrication

Pressure Feed Being Used

NEARLY every automobile maker has announced several changes in the motor lubrication for his 1913 models, and while the general plan with many of them remains unaltered there have been minor changes which indicate a feeling of uncertainty as to the adequacy of previous systems. One maker who relied on the splash system has installed a positive feed system to all of the crankshaft and connecting rod bearings; another that used a pressure feed to the crankshaft and lower connecting rods with splash to the wrist pins and cylinder walls has eliminated the splash and now feeds by pressure up the connecting rods to the wrist pins, the overflow reaching the cylinder walls. Another maker has added an interconnection between the throttle and the lubrication feed, insuring more oil to the bearings with a wider opening of the throttle and vice versa. Still another maker, who made use of baffle plates in the open ends of the cylinders, has eliminated them. A score of makers have wrestled with the problem of eliminating smoking on closed or partially closed throttle: So the program of changes proceeds, all indicating an unsettled situation, due primarily to the greater requirements on the oiling system because of higher crankshaft and piston speeds as well as increased motor efficiency. In a word, the maker has learned that when the power output of the motor has been increased by larger-diameter valves, by lighter pistons and connecting rods, by larger-diameter crankshafts, by stouter crankcase and cylinder casings, by multi-point ignition, by improvements in carburetion, there must be commensurate improvements in the oiling system, because truly it is the lubricant that keeps the motor working.

There have been several makers who for the present season overlooked the question of perspective between the lubrication system and the other systems of the car. Heretofore the lubrication one had been the acme of satisfaction and they concluded that it would continue so, but discovered an error. It lagged behind. They learned the lesson that perspective enters into every department of the motor and chiefly into the lubrication system. After discovering their error some of them added auxiliary systems, only to incorporate them into the car total at the first opportunity.

Not only have the improvements in motor design placed a heavier load on the oiling system, but municipal regulations against smoking have rendered higher efficiency imperative. This has introduced the problem of good lubrication at slow speeds, and chiefly with partially closed throttles. To handle this question called for action based on the fact that with the throttle in a partially closed position there is more of a vacuum created above the piston and consequently a stronger tendency to pull the oil up the cylinder walls past the piston and into the combustion chamber, where it is burned and passes through the exhaust system as smoke or rests as carbon in the combustion and valve chambers. Various schemes have been utilized to counteract this suction, if the expression may be used. A common one has been the scraper groove in the piston in conjuction with holes drilled from this groove to the inside of the piston thereby setting up an equilibrium of pressure in the space beneath the piston and whatever space there remains between the piston and the cylinder wall. This has given special satisfaction in many places. The anti-smoke crusade has also brought improvements in testing the oil level in the crankcase as well as in giving greater accessibility to the drain cock of the crankcase and also the overflow cock. Both of these are now in many cars, fitted with upwardly extending handles, permitting of their operation without having to reach down to the base of the crankcase or make use of a special door in the underpan.

Extra life has been given the oil used in many motors by the discontinuance of the splash system, which has been gaining followers each season for several years. With the big lower end of the connecting rod dipping into the oil level the lubricant was unnecessarily churned and only a very small percentage of that splash reached the desired points. The viscosity of the oil was needlessly lowered. To avoid this the trough oiling system was introduced with the small scoop on the end of the connecting rod. Even with this the adequacy was not what was at all times desired, and the next step taken by many makers was the entire elimination of the splash and the adoption of the pressure system, a trend of progress which has been carving its way in Europe for the last 5 years. It is a certainty that 1914 will witness vast strides in this direction.

S.A.E. Detroit Branch Meets

Decides That Negotiations With Bureau of Standards Be Left to National Council—Discuss Bearing Standards

DETROIT, MICH., Aug. 3—The keynote of the meeting of the Detroit Section of the Society of Automobile Engineers held on August first was the discussion of the proposed standards work to be done for the automobile industry by the Bureau of Standards at Washington. It was the general sentiment of the members of the section present that any negotiations which are to be carried on with the Bureau should be done by the national council of the Society, since the communications of this body would carry more prestige than would those of any local branch of the Society. A motion made by H. W. Alden discharging the Detroit committee which was appointed to confer with the officials of the Bureau of Standards and recommending that the work be carried on by a committee appointed by the National Council of the Society, was carried. It was also recommended that J. O. Heinze and E. J. Stoddard be placed on this national committee.

D. F. Graham, expert on bearings, stated that one thing which could be standardized to immense advantage and on which there is a wide difference of opinion is the exact size of gauges and plugs for accurate measurements. There is a difference in the manner of use of micrometers, which often results in varying ideas of the same accurate dimension. It is hard to tell just what the size of a hole or the diameter of a piece is. Standards for such measurements should all agree, and since each manufacturer can not afford to carry such a set, due to its expense, one set should be kept for the use of all.

In further discussing the subject, Mr. Heinze made the Society's position clear by stating that it should ask the Bureau of Standards to tell it only those things which it cannot find out for itself, due to the lack of apparatus for such research, or to lack of time to carry on such exhaustive tests as were necessary.

In speaking of the proposed testing laboratory in Detroit, for the joint use of all automobile manufacturers, as proposed at the summer meeting of the entire Society, Mr. Heinze stated that while some of the privately owned laboratories now existing are good, none of them are complete. If there was one which had some eminent professor in charge who was unbiased by commercial considerations, and who had all the time he needed to do his work, such a laboratory would be of great benefit. The expense of such an institution would be much less than the total cost of operating individual laboratories. The project would cost about $100,000, and Mr. Heinze stated that unless it could be carried out as it should be, it would better be left alone.

Hub After Joy-Ride Officials

Investigation Shows That City Spends More for Maintenance Than Cars Cost Originally—Municipal Garage Possible

BOSTON, Aug. 2.—Following the discharge of Chief Clerk Casey, of the School Commission, of a charge of joy-riding in using the motor car belonging to the commission, the Boston Finance Commission has inserted its probe into the care and maintenance of the city motor cars. It was Casey's second offense, and the first time he suffered a reduction in salary of $500 a year. It is expected that when the report of the Finance Commission is made public some startling figures will be given out and there may follow some drastic action. According to the City Auditor's books $89,473.35 was spent during the past fiscal year on the 54 cars and trucks in the service of the city. The figures show that the Public Works department spent the larger amount, but as it has 17 cars this is not surprising.

Mayor Fitzgerald, although he has but one car, has spent $5,494.09 for its maintenance, or more than the car cost the city new. This is nearly as large as the amount spent for the maintenance of all seven cars by the Police Department. The Mayor has just bought a new car for $3,200. The cost of maintenance for the departments follow: Bath department, three cars, $6,845.07; park department, four cars, $7,781.67; health department, four cars, $3,327.04; school department, two cars, $4,505.48; public works department, Central office, one car, $1,162.31; bridge and ferry division, three cars, one out of use, $4,755.66; paving division, three cars, $5,706.29; sanitary division, two cars, $1,947.87; street cleaning division, two cars, $3,981.50; sewer division, four cars, $4,004.24; water division, three cars, $7,989.17.

That some of the cars are used for evening and Sunday outings is well known. When the matter of joy-riding came up before the council passed an order to have all city cars marked, but this is a joke, for the cars bear little metal plates a few inches square with initials only on the sides near the running boards where they are not noticed. It is expected that following the Finance Commission's report there will be established a municipal garage where a check can be kept on all cars. Now they are kept anywhere and the chauffeurs can get them any time they want them and the officials get the cars, too, at any old time.

NEGOTIATIONS have been completed for the purchase of the E-M-F Studebaker plant at Port Huron, Mich., by the Havers Motor Car Company, which has met with much success in the building of moderate-priced six-cylinder cars. The Havers company will take immediate possession and push its plans for the greatly increased output for 1913.

London's Rubber Market

Prospects of Artificial Product Has Depressing Influence During Trade Period Ending June 30

Cheaper Rubber Does Not Necessarily Mean Cheaper Tires—Production Figures and Prices

LONDON, Aug. 1—Plantation rubber had a cheerful effect on an otherwise dull market, considering the commercial period ending June 30. The synthetic rubber scare, as it was called, depressed rubber shares and it was on that account that a strong demand, as shown at the plantation auction of the end of June, was so cheering. The lack of stability of the rubber market is adequately reflected in the effect of the synthetic rubber announcement, which almost precipitated a panic. In the interim crude rubber is in fair demand, selling at 4s. 6 3-4 d. ($1.13 1-2) per pound. But this showing merely indicates something of the extent to which rubber enters the arts. Those who have occasion to use rubber, if they run short, find it expedient to replenish the supply in their vaults, and when the synthetic scare struck the market, purchasing of crude was the natural order of the day. The result of this heavy buying movement was favorable to a hardening market, but there is nothing in this situation which would lead one to believe that plantation (rubber) shareholders feel very comfortable.

There are two possibilities in conjunction with the announcement of synthetic rubber, *viz.*, that plantation rubber is likely to get a severe setback, and that British tire makers are confronted by a demand for lower prices for their wares—the average Britisher still believes that the prices are high for the tires, due to the high price of crude. The more enlightened English motorists, however, point out that the percentage of actual rubber in a tire is very low. They also say: the fabric, if it is of the best grade, and the expenditure represented in the cost for skilled labor employed in tire making, coupled with a rather heavy selling propoganda, are sufficient grounds for believing that the cost of tires to motorists here will scarcely be lowered, even assuming that synthetic rubber takes hold of the market to the extent of supplanting plantation products.

It is pointed out that tire makers have but themselves to blame for the rather awkward situation which confronts them. The average man thinks that it is the high price of crude which serves as the foundation for the high price for tires. Naturally these mistaken individuals, of which there is a legion, will clamor for a reduction in the price of tires, the very minute that the cost of crude is tapered down. That they will be disappointed, is almost certain. In order to balk an awkward situation, it is claimed in some quarters that tire makers are depreciating the claim that synthetic rubber is in the nature of a great discovery. One individual has expressed the opinion that synthetic rubber has a very high nuisance value. Whether or not the users of rubber would prefer to pay enough to suppress the production of rubber on a synthetic basis, remains to be seen.

Deep Price Cuts Not Probable

For the near future, it is claimed that the market position of Para rubber is secure. One feature which supports Para crude is the progressive consumption of rubber. One point is overlooked in the attack which is being made upon synthetic rubber by tire makers in England, viz.: When it is said that synthetic rubber will fall below the quality required in the manufacture of tires, no mention is made of the possibility of relieving the pressure on Para, through the simple expedient of employing synthetic rubber in the many situations which now command the use of either Para crude or seed crude *via* plantations.

There is one thing which cannot escape the notice of the market. The synthetic rubber scare is almost sure to snub plantation effort. This, in the face of a progressive demand, spells stability of Para for several years to come if synthetic rubber fails to take a strong production position in the near future. Indeed, it is quite plain that the three forces here in operation must lead to a famine of the best grades of crude. The three forces are: Increasing rate of demand, reduced plantation output, and the failur (if it does fail) of synthetic rubber to make up for the deficit. All of which, taking it for granted that Para output will hold its own, but no more.

The output of Para crude at the present time is reported statistically, about as follows:

From Brazil, for 12 months ending June 30, including Cancho, 32,360 tons. Just to show that this source of supply is not progressive, it is only necessary to state that the output from these sources was 37,565 tons and 32,140 tons respectively for the two preceding seasons.

At the end of this year (June 30) the stock of crude in hand, but not shipped, at the port of Para, was 3,050 tons. This is in the nature of an actual reduction of the Para annual hold-over of crude by some 1,500 tons as compared with last year.

The reduction in crop hold-over at Para of 1,500 tons is offset by the lower production of one of the two preceding years, whereas a progressive demand for crude is shown, not by any increase of movement in Para deliveries, but in the movement of plantation crude. In this connection it is pointed out that, if tire makers do not support the plantation market, it is then, quite evident that plantation crude enters into the other arts, relieving Para to that extent, thus enabling tire makers to monopolize Para in their more exacting requirement.

Referring specifically to plantation production of crude, it is reported from the Federated Malay States that over 542,877 acres of land are now devoted to rubber cultivation. This grand total of acreage was due to an increase of upwards of 70 per cent. increase in Malay production between 1910 and 1911, the latter being the date of the last authentic acreage report from these states.

The conditions at Ceylon are backward as compared with the progress which has been recorded for Malay. It follows, therefore, that synthetic rubber will strike the hardest blow at Ceylon. But the Ceylon planters go in for supplementary crops of tea, coffee, and cocoa. In this way expenses are kept down and the effect of a depressed rubber market will scarcely be so pronounced.

Synthetic Bogy May Scare Investors

In the Straits Settlement, if financial tinkering in London is a reflection plantation rubber is seeking additional financial support, just at a time when this support is lacking. In the same way, Kepitigalla rubber conditions are somewhat backward. The rubber output, as reported by the Kepitigalla Estates during the year ending March 31, was 90,025 pounds. But there is a certain measure of consolation in this report, due to the actual increase of 48,601 pounds for last year over the previous year. Then, too, these estates score on tea and pepper. The actual results of the combined efforts at rubber, tea, and pepper growing enabled these estates to declare a 4 per cent. dividend on the capital stock this year, this being an increase from the dividend of 2 1-2 per cent. which was declared last year. The rubber produced brought an average price of 4s. 2d. ($1.12) at the English auction, this being low in view of the higher average price of 5s. 7 1-2d. ($1.40) for the previous year.

It would scarcely be of interest to bring these matters of the rubber market to the attention of the average automobilist in the ordinary sense, but it is worthy of note that plantation rubber promised to serve as the balance wheel for Para, and, with a synthetic scare confronting them, it is more than likely that British investors will withdraw their support, letting plantation enterprises sink or swim as best they can. It is feared in some quarters that plantation enterprises are not sufficiently advanced to strike out, unbuoyed by outside financial aid.

New York Rubber Show

Twenty-two Nations Represented in Exposition Which Will Open Next Month in the Palace

Comparisons To Be Made of the Value of the Indigenous and the Plantation Products

UNDER the auspices of twenty-two governments, each of which will be officially represented by accredited delegates, the International Rubber and Allied Trades Exposition will open September 23 at Grand Central Palace and will remain open until October 3. Most of the twenty-two governments concerned in the undertaking are states of the British empire, South and Central American republics and territories of the United States, The list includes the following: Ceylon, Straits Settlements, Federated Malay States, British Guiana, Jamaica, Dutch Guiana, Belgium, France, States of Para and Manaos and the Republic of Brazil, Southern India, Mexico, Portugal, Honduras, Costa Rica, Indo-China, Lower Burma, Hawaii and the Philippines.

Already the booths are being prepared to house the exhibits although 6 weeks will elapse before the opening of the show.

The general plan of the expositions is comprehensive and is being carefully worked out. In the main exhibition hall of the Palace, where the automobile show was held last winter, will be installed the exhibits of rubber-making machinery and rubber manufactures. Here will be given actual demonstrations of the various processes that lie between the collection of latex to the production of automobile tires and other finished goods.

The lobby, entrance, grand stairway and even some of the pavement in front of the building will be covered with rubber to demonstrate the value of the substance in that way.

The mezzanine floor, where the commercial cars were shown last winter, will house the exhibits showing the reclaiming of rubber, compositions and chemicals.

Hawaiian Product Will Be Shown

The floor above will be devoted to exhibits of crude rubber in various shapes and forms. Brazil will have an immense booth showing the importance of the indigenous production and close by will be the exhibit of Ceylon, depicting the condition of the plantation industry.

One of the most interesting sections of the show will be the exhibit from Hawaii. Recently the cultivation of rubber in the Hawaiian archipelago was rewarded by success and 1 ton of plantation rubber grown from seeds of the Hevea Brasiliensis will be shown. The industry has not made very satisfactory progress in the Philippines, having had a poor start.

Probably the most valuable and illuminating feature of the show will be the comparison that will be made of the relative value to the industry and public at large of the indigenous and plantation product. Mr. Manders called attention to the fact that the plantation rubber marketed so far this year in the regular fortnightly auctions in London is far in excess of the 1911 figures for the same period.

He looks for the maintenance at least, of the indigenous yield and consequently expects a tremendous increase in the volume of crude rubber susceptible to manufacturing uses of the industry.

Mr. Manders says that with the increase in the volume of crude rubber, thousands of things not made of rubber at present will be made of rubber then and that fully 1,000 new uses will be found for the substance.

In spite of the large additional demand, he states that he expects a gradual reduction in the price of crude because of the augmented supply from the plantations which can produce rubber at a profit at 25 cents a pound.

Doubtful as to Artificial Rubber

He holds that synthetic rubber has made no material advance in 20 years, but that it may come eventually. In his desk at the Palace he has a bit of vulcanized synthetic rubber which he says cost $120 a pound to make out of Russian turpentine. In appearance and resilience this bit of rubber seems like ordinary vulcanized Para. As to its values as a commercial proposition he is not enthusiastic.

"I hope it can be made on a commercial basis," said Mr. Manders, "because it might prove valuable as a mixture with gum rubber for certain uses. Every factor in the problem is important enough to deserve close study, because the discovery of an element that can serve to supply a need of the public is always important and if the mixture of synthetic rubber with natural gum will serve to release some of the present or future demand for natural gum, it will release a certain amount of crude rubber from its present uses and allow of its being used in some other direction."

During the exposition an International Rubber Congress will be in session for at least a week. The convention hall will be located on the fourth floor of the Palace above the crude rubber floor. Planters, scientists, chemists, manufacturers and others will attend the congress which will be presided over by Henry C. Pearson.

President Taft has agreed to act as patron of the exposition on account of the tremendous importance of the rubber industry to the United States. There are seventy prominent American business men on the advisory committee, including representatives of the United States and practically every republic and dependency on the western continent. A. Staines Manders, who managed the London expositions, is in charge.

The conclusions reached among the men who make it a point to see into the future of market situations, may be summed up as follows:

A—Tire makers have little to fear from any of the causes which so convulse the rubber market, due to the small percentage of actual rubber used in tire production.

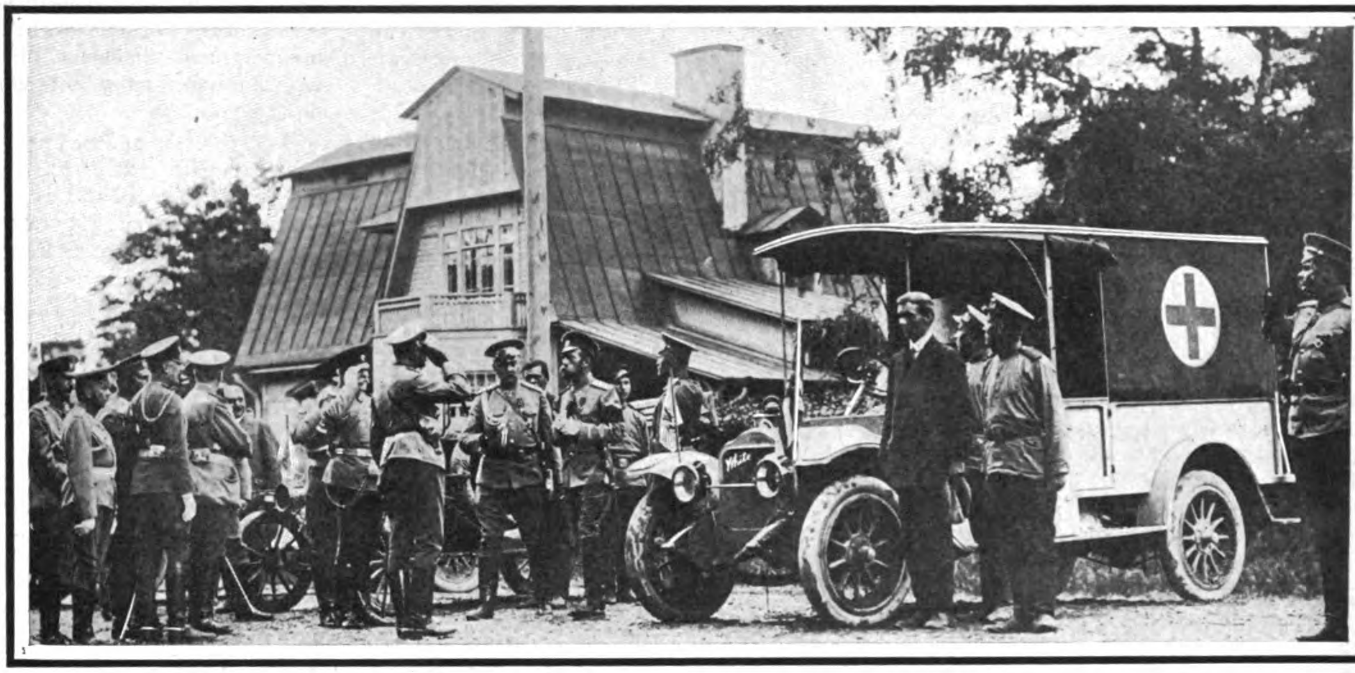
B—The commercializing of synthetic rubber production will take considerable time, and, in the interim:

C—Plantation enterprises will suffer, due to lack of British financial support. In the meantime:

D—Para will remain, as it always has been, the source of fully 90 per cent. of the actual supply of quality crude.

Referring to synthetic rubber, that recently discovered compound, representative of one of nature's strange substances which, fortunately or otherwise, has strayed into the world of mechanics, the strength of its possibilities is reflected in the savage way that certain of the tire interests attack it; the best argument that they present is that synthetic rubber is another echo of an old story. In the meantime the compounding of this product has been accomplished on a definite basis.

The process seems to be capable of perfection on a commercial basis, and fortunately, the raw material required in the process is abundant in nature and low in price. In the process as it has been outlined, there is no waste products. The two outputs are (a) synthetic rubber and (b) alcohol (fuel). The synthetic rubber is in two grades—(1) of a fluid consistency, and (2) a solid residuum. The grade 1 latex, if such it may be called, is for use in the production of rubber products in the ordinary way; the grade 2 solid constituent serves as a foreign substance, so called to put into a batch of natural rubber latex, to form a tough compound, as the treads of tires, where great toughness is the prime requisite. The fuel by-product may not be of present great value, but gasoline in England is either scarce or controlled as to price; at all events it would take the acumen of a Yankee to make a purchase of gasoline at a shilling (about 25 cents). The ruling price at supply stations is variable, at over a shilling per gallon. As a rule, the retail price of gasoline in England is about double what it costs in the United States.



The Czar of Russia inspecting the fleet of White vehicles which took part in the recent military maneuvers

WHITES Bought By Russia—Russia has bought the five White cars which went through a test arranged by the Russian Government to determine the adaptabilty of motor vehicles for army service in all of its branches. A reliabilty run of 1,960 miles over very hard roads was held, in which the pick of European cars and the five Whites entered. After a rigid examination, the White cars were found to be in perfect condition.

Ruby Chemical Company Moves—After July 15, the Ruby Chemical Company will be located at 157 West State street, Columbus, O.

White Handles Marion Advertising—Mr. W. McK. White has moved to Indianapolis, Ind., to become advertising manager of the Marion Motor Car Company.

Stratton Joins the Everett—Mr. E. Vincent Stratton has resigned as sales manager for the Packard Dealers at Albany, N. Y., to affiliate himself with the new Everett organization.

Brown Designs Motor Truck—Mr. J. Grave Brown, of Groton, N. Y., formerly chief engineer of the Monarch Roller Company, has designed a motor truck especially adapted for contractor's service.

Hupmobile in New Quarters—Frank P. Anderson, Syracuse agent of Hupmobile cars, has removed to his new location at No. 600 South Salina street, taking the garage formerly occupied by the Joseph J. McCarthy Taxicab Company.

Kelly Truck Shows Speed—A fire occurred recently at Mr. E. S. Kelly's residence, Whitehall, Pa., which is about 10 miles away from the nearest fire engine house, and was practically saved by the quick work of the Kelly truck, which made the trip in 14 minutes.

Cole Adds to Service—C. J. Corkhill, a Middle West automobile man with experience, has been appointed assistant sales manager of the Cole Motor Car Company, with headquarters at Omaha, Neb. J. R. Moler is to hold a similar position in the territory west of the Rockies, up and down the coast. His headquarters will be with the main Cole distributors, but he will do continual traveling among Cole agents. J. R. Hamilton will be associated with Mr. Moler as the west coast Cole service expert. W. B. Lacer is second Cole service expert added.

Indianapolis Tire Men Activities—The Indianapolis sales and Indiana distributing branch of the Diamond Tire Company has moved to 431-433 North Capitol avenue, Motor Row, Indianapolis. A new three-story building has also been completed at Capitol avenue and Michigan street and has been occupied by the sales branch of the Goodyear Tire Company, the Carl Fisher company, which has the agency for the Stutz and Packard, the Archey-Atkins company, distributors of the Pierce-Arrow, Detroit electric and Hudson, and the Ideal Motor Car Company.

Wheel Tax Repeal Asked—Repeal of the wheel tax on automobiles is urged by the commissioners in Washington, D. C., and W. P. Richards, assessor of the district. The officials declare the tax to be unjust and unequal in its workings, as it was imposed by Congress without request of the municipal authorities for an option as to its advisability. At present there are four charges against motor vehicles. First—an operator's permit must be obtained for which a fee of $2 is charged; second, an identification tag is required at a cost of $2; third, a wheel tax is assessed against all automobiles; fourth, should the automobile be a public vehicle, a special tax license is required for each vehicle not exceeding ten passengers.

Overland Enlarges Salesroom—The Northwestern Overland Company, of Minneapolis, Minn., has added to its salesroom so as to facilitate better handling of its goods.

Automobile Club May Buy—The Cincinnati Automobile Club, Cincinnati, O., is negotiating for the property known as the Williamson farm on Colerain pike near Groesback.

Paris Resigns from Olds—Rupert E. Paris, general sales manager and assistant manager of the Olds Motor works, has resigned. His resignation is to take effect September 1.

Tags for 75,000 Motors—Pennsylvania will order 75,000 license tags for the year 1913, and increase of 15,000 over the present year. The color adopted for 1913 is olive-green with white letters and figures.

Bonness Takes Miller Tire Agency—C. J. Bonness, formerly with Chancelor & Lyon, more recently with the U. S. Tire Company, has taken the agency for the Miller tires in Seattle, Wash.

Nichols Assists Percy Owen—F. W. Nichols, former manager of the Whitten-Gilmore Company, of Boston, has been made assistant to sales manager Percy Owen, of the Chalmers Motor Company, Detroit, Mich.

Schmelz is Now With Poss—W. F. Schmelz, formerly with the Detroit Steel Products Company, has been made special sales representative for the Poss Motor Car Company, with territory in Kentucky, Indiana and Ohio.

Dallas Studebaker Branch Expands—C. W. Hartman, branch manager for the Studebaker Corporation at Dallas, Texas, has had his territory extended somewhat. A subsidiary distributing point to this branch has been opened at San Antonio.

Barnesboro's Automobile Tour—The business men of Barnesboro, Pa., will conduct an automobile tour through Indiana county August 1. The purpose of the tour is to boom Barnesboro and the fourth annual street fair to be held August 12 to 19.

East Takes Olds Advertising Reins—G. L. East, former advertising manager of the Olds Motor Works of Lansing, Mich., has taken a similar position with the Amplex Motor Car Company, of Mishawaka. His headquarters will be in Chicago, however.

Bacon to Join Packers Service—Mr. Carter M. Bacon, former inspector for the American Locomotive Company of their own Alco cars, at their factory in Providence, R. I., will join the Packers service in the capacity of service department manager.

Automobile Plates for 1913—Secretary of State Lazansky has contracted for 90,500 pairs of automobile license number plates for 1913. The contract, for which bids were invited, was awarded to the Manhattan Supply Company, of New York, which furnished the plates used this year.

Utah Club Helps Transcontinentalists—The Automobile Club, of Utah, has opened a free bureau of touring information at 251 South State street, Salt Lake City, Utah. Tourists are handed cards and asked to write back to the club giving road conditions and information for others following.

Getting Ohio Show Ready—Dealers in automobiles in Columbus, O., and some of the manufacturers of both pleasure cars and motor trucks are preparing to have a large exhibit at the Ohio State Fair and Columbus, O., Centennial Celebration which will be combined and will take place August 26 to 31.

Indianapolis Wants Motor Equipment—The city authorities of Indianapolis have under consideration the adoption of motor equipment in the street cleaning department, to include several motor driven sweepers and sprinklers. Concerns manufacturing such apparatus are being communicated with by the board of public works.

Slater Joins Mighty Michigan—The latest addition to the forces of the Michigan Buggy Company is William J. Slater, of the Firestone Tire & Rubber Company. He becomes assistant sales manager of the Michigan. Mr. Slater was advertising manager of the Firestone Tire & Rubber Company prior to coming to Kalamazoo.

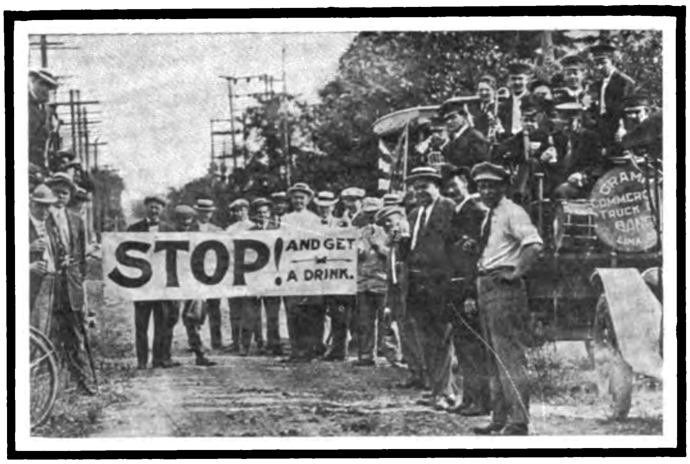
Banquet at Nyberg Plant—After a parade around the city of Anderson, Ind., the employees of the Nyberg Automobile Works gathered around a banquet table in one of the large buildings of the Nyberg plant, in celebration of the splendid record made by Nyberg cars in the recent tour of Indiana-made automobiles through four states.

Yosemite Park's Bad Roads—Despite the requests of several California Congressmen, that automobiles be allowed in Yosemite Park this year, Secretary of the Interior Fisher has ordered that motor cars be not allowed in the park. The superintendent has reported that the roads are too narrow and steep for safety. Legislation is to be pushed at the next session to improve these roads.

Selling Electrics in Fleets—The Waverley Company of Indianapolis, Ind., has recently filled an order from the Louisville Lighting Company of Louisville, Ky., for six Waverley Electric roadsters for the use of the latter's trouble and repair departments. These are in addition to four light delivery wagons of the same make and for the same service. The picture on this page represents these roadsters drawn up before the Waverley office and the factory ready for shipment. The light delivery wagons will be forwarded in a later shipment.

Packard Engineering Force Developments—The engineereing forces of the Packard Motor Car Company, Detroit, Mich., have been added to, J. G. Vincent having resigned as assistant engineer to Howard Coffin, of the Hudson company, to take an engineering position with the former concern. Russell Huff has been made consulting engineer and C. J. Moore manufacturing engineer, of the Packard Company. These two men, together with Mr. Vincent, will form an advisory board, which will have general supervision of the engineering affairs of the company.

Fleet of Waverley electrics now in the service of the trouble and repair departments of the Louisville Lighting Company



Four-States tourists were held up by the Gramm Company

Hupp-Yeats Electric in South—Hupp-Yeats electrics will be represented in the South, A. J. Carter having been appointed southern wholesale representative.

Texas Studebaker Dealers Co-operate—The Studebaker Automobile Dealers of Texas have organized. The stated object of this organization is that the Studebaker dealers of Texas may co-operate for the further distribution of the cars in the state.

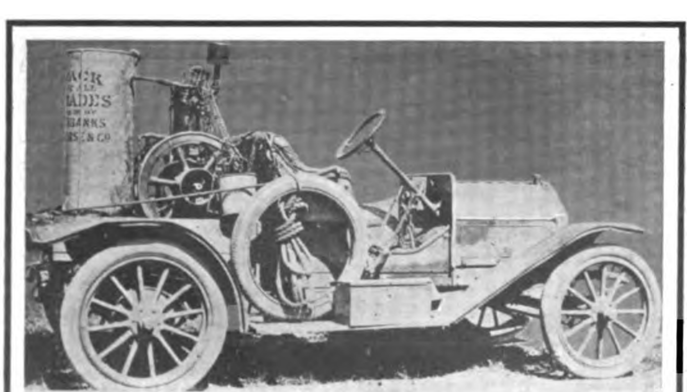
Lexington Selects Boston Quarters—The Lexington Company, of New England, has leased the building on Northampton street, Boston, formerly occupied by the Premier branch as a service station, the former company using it for the same purpose.

Clark-Carter 1913 Plans—The factory of the Clark-Carter Automobile Company, Jackson, Mich., manufacturer of Cutting cars, was recently visited by a number of dealers who inspected the plant, talked over the 1913 campaign and renewed their contracts.

Giltner Goes to Plow Maker—C. E. Giltner, who for several years has been manager of the Omaha branch of the Rambler factory, resigned August 1 to go to Moline, Ill., to become manager of the Velie automobile department of the John Deere Plow Company.

Wiles Experiment Superintendent of Velie—E. H. Wiles has accepted a position with the Velie Motor Vehicle Company, Moline, Ill., being appointed superintendent of experimental work, a department which is meeting with special attention from the Velie company.

Taxi Motor Cab Company Grows—The Taxi Motor Cab Company, of Boston, has just installed fifty new cabs, all painted light gray. They are larger than the old machines formerly used by the company, having a seating capacity of five instead of four, and electric lights to replace the oil lamps.



Studebaker 30 which replaces forty-six horses on Wyoming ranch

Baltimore Locomobile Branch Moves—The Locomobile Company, of America, Baltimore, Md., is now in its new branch house 109 to 121 West Mount Royal avenue, formerly headquarters of the Stoddard-Dayton Auto Company branch. T. W. Wilson is manager of the local branch of the Locomobile company.

Shur-Go to Make Its Starter—Announcement has been made by the Shur-Go Starter Company that it has purchased the patents and equipment required in the manufacture of its self-starter, and contemplates the manufacture of the device in New York. It is stated by the company that deliveries will be made by September 1. The officers of the new organization are: James E. Taylor, president; W. G. Rand, vice-president and general manager and E. Chamberlain, secretary and treasurer.

Automobile Incorporations

AUTOMOBILES AND PARTS

Boston, Mass.—Elliott Motor Engine Company; capital, $300,000; to manufacture engines. Incorporators: G. R. Elliott, F. P. Harris.

Brooklyn, N. Y.—Penn Automobile Company; capital, $5,000; to engage in automobile business. Incorporators: L. Wendell, H. Partridge, M. Wolf.

Brooklyn, N. Y.—Cold Radiating Company; capital, $250,000; to manufacture radiators. Incorporators: F. Baker, Irene I. McCarthy, R. L. Weaver.

Buffalo, N. Y.—Mutual Motor Car Company; capital, $125,000; to manufacture motor cars. Incorporators: Albert Poppenberg, F. C. Carter, O. E. Yeager.

Cambridge, Mass.—Blake Automobile Company; capital, $100,000; to engage in automobile business. Incorporators: E. C. Blake.

Camden, N. J.—Service Motor Truck Company; capital, $50,000; general automobile business. Incorporators: R. L. Smith, C. D. Hackett, E. J. Eldridge.

Cedarburg, Wis.—A. H. Meyer Motor Car Company; capital, $25,000; to manufacture automobiles. Incorporators: J. Armbruster, J. Dietrich, J. F. Bruss.

Cincinnati, O.—Welbon Motor Car Company; capital, $25,000; to manufacture automobiles. Incorporators: W. E. Welborn, H. S. Leyman, C. D. Wilson, C. W. Shepler, H. S. Welbon.

Cincinnati, O.—Cincinnati Motor Car Company; capital, $10,000; to manufacture automobiles. Incorporators: C. D. Wilson, H. E. Heisey, C. W. Shepler, J. C. Miller.

Cincinnati, O.—Central Automobile Company of Kentucky; capital, $25,000. Incorporators: W. Dickerson, G. Koehler, M. Emrich.

Cleveland, O.—Arter Automobile Carriage Company; capital, $20,000; to manufacture automobiles. Incorporators: J. S. Arter, B. Hexter, J. B. Buhl, C. A. Chapman, C. B. Lammon.

Columbus, O.—Central Motor Car Company; capital, $25,000; to manufacture automobiles. Incorporators: Anna Herr and others.

Detroit, Mich.—Ford Motor Car Company; capital, $750,000; to manufacture automobiles.

Detroit, Mich.—Manufacturers' Sales & Engineering Company; capital, $1,000; to deal in automobiles.

Detroit, Mich.—Hercules Motor Truck Selling Company; capital, $50,000; to engage in automobile business. Incorporators: A. Smith, J. O. Murfin, W. E. Webb.

Detroit, Mich.—Durham Easy Truck Company; capital, $50,000; to manufacture trucks. Incorporators: J. M. Mackey.

Kansas City, Mo.—Hudson Latham Company; capital, $100,000; to manufacture motors. Incorporators: W. A. Latham, C. B. Boyd, W. M. Boyd, B. Downing.

Jamesburg, N. Y.—Ex-Cel Motor Truck Company; capital, $250,000; to conduct a general automobile business. Incorporators: T. C. Corwin, A. Englehart, A. A. Kelley.

Newark, N. J.—Sullivan Automobile Company; capital, $25,000; to engage in a general automobile business. Incorporators: J. Sullivan, C. Bagnole, W. N. Frankel.

New York City.—Standard Automobile Company; capital, $10,000; to deal in automobiles. Incorporators: E. H. Erichman, H. D. Chapin.

New York City.—Wallace Automobile Company; capital, $300,000; to manufacture automobiles. Incorporators: S. E. Robertson, H. W. Davis.

Reno, Nev.—Mack Auto Company; capital, $50,000; to engage in the automobile business. Incorporators: M. J. Mack and others.

South Bend, Ind.—South Bend Auto Body Company; capital, $20,000; to manufacture automobile bodies. Incorporators: V. E. Paxson, S. W. Nicholson, J. C. Paxson.

St. Louis, Mo.—Burns Ramsden Motor Car Company; capital, $10,000; to manufacture and deal in automobiles. Incorporator: Louis N. Burns.

St. Louis, Mo.—Model Auto & Sales Company; capital, $3,000; to engage in the automobile business. Incorporators: Oscar Sonntag, Roy E. Stutts, Otto F. Karbe.

Toledo, O.—W. H. McIntyre Company; capital, $10,000; to engage in the automobile business. Incorporators: W. H. McIntyre, William Vollmayer, Frank Carabin, Edward Lakey, Frank Kelly.

Westfield, N. J.—Darby Motor Car Company; capital, $25,000; to engage in the automobile business. Incorporators: L. D. Darby, H. C. Darby, A. B. Darby.

GARAGES AND ACCESSORIES

Akron, O.—Akron Airless Tire; capital, $56,000; to manufacture puncture-proof tires. Incorporators: W. S. Brooks, T. N. Thompson, F. H. Beyea, H. L. Cole.

Akron, O.—Majestic Rubber Company; capital, $3,000; to manufacture and deal in tires and rubber goods. Incorporators: A. L. Neiswanger, O. W. Baum, J. H. Ault, J. A. H. Myers.

Baltimore, Md.—Jewell Electric Company; capital, $10,000; to manufacture electrical devices. Incorporators: J. C. M. Lucas, H. Percy Lucas, Clay Jewell.

Boston, Mass.—Maiden Gas & Electric Company; capital, $15,000; to manufacture electrical devices of all kinds.

Will Inspect European Branches—W. H. Lalley, foreign sales manager of the Studebaker Corporation, will leave Detroit this week for a tour of inspection of the firm's European branches.

Australian Visits Studebaker Plant—R. E. Kemsley, Studebaker distributer for Australia, New Zealand and Tasmania, with headquarters at Melbourne, Australia, was a recent visitor to the Detroit plant.

Groff Takes Boston Paige—H. M. Groff has been sent to Boston to take charge of the New England branch of the Paige-Detroit car, and he will make his headquarters in Boston at the local agency on Hereford street.

King Appoints Canadian Agent—The King Motor Car Company has designated the Matheson Automobile Company, of Toronto, Canada, of which Scott Innes is manager, as its sales agent for a large part of Ontario.

New concrete building of Firestone Tire Company in St. Louis

Automobile Incorporations

Yonkers, N. Y.—International Auto Lamp Manufacturing Company; capital, $50,000; to manufacture automobile lamps. Incorporators: Hyman Age, Thomas Cunningham.

Buffalo, N. Y.—Hall Automobile Coupler Company; capital, $250,000; to manufacture a patent hose coupling. Incorporators: John W. Blackman, Lucas M. Hall, Edward S. Hall.

Cincinnati, O.—Oil Industrial Company; capital, $10,000; to deal in oils, greases, belt dressings, etc. Incorporators: E. G. Holden, John C. Rogers, Ezra H. Passel, George C. Schmidt, Jr., E. R. Heisel.

Cincinnati, O.—Swing Wheel Company; capital, $50,000; to manufacture automobile wheels. Incorporators: Richard E. Werner, Rupert H. Langdale, C. A. Bickett, Richard A. Bickett.

Cincinnati, O.—Victor Auto Parts Company; capital, $20,000; to make automobile accessories. Incorporators: William J. Corcoran, Edward B. Corcoran, John L. Corcoran, Harvey R. Corcoran, H. R. Kerans.

Cleveland, O.—Knox Rubber & Supply Company; capital, $10,000; to manufacture rubber goods, tires, etc. Incorporators: R. A. Lang, C. S. Wachner, H. H. Burton, A. S. Dael, P. F. Blaine.

Dayton, O.—Automobile Lamp Control Company; capital, $15,000; to make automatic lamp-control devices for automobiles. Incorporators: Henry Ehlen, Ernest A. Eastman, William B. Meeker.

Detroit, Mich.—Detroit Battery & Ignition Company; capital, $200,000; to manufacture storage batteries, automobile lighting and ignition devices, etc. Incorporators: Charles R. Baxter, Louis C. Knop, Charles L. Tomlinson.

Detroit, Mich.—Kenyon Searchlight Company; capital, $75,000; to manufacture searchlights and other automobile accessories. Incorporators: H. B. Kenyon, H. E. Bloomingdale, C. F. Bloomingdale.

Detroit, Mich.—Michigan Motor Specialties Company; capital, $20,000; to manufacture automobile accessories. Incorporators: Nellie M. Beck, Charles W. Beck, Charles Wright, Jr.

Detroit, Mich.—Mote Demountable & Detachable Rim Company; capital, $30,000; to manufacture rims. Incorporators: Herman Mote, H. L. Beck, W. M. Elliott.

Dunkirkville, Ind.—Anto Transportation Company; capital, $85,000; to engage in the transfer and transportation business. Incorporators: G. W. Carr, J. H. Prescott, Thomas E. Boyd, F. Bertolette.

Hudson, N. Y.—Warren Street Garage Company; capital, $3,000; to engage in the garage business. Incorporators: John T. Hester, Henry B. Hester, Dennis Hester, Jr.

Middletown, Pa.—Middletown Auto Club; to advance the interest of local automobile owners. Incorporators: D. W. C. Laverty, A. H. Luckenbill, I. O. Nissley, W. P. Evans, T. M. Yost.

Nashville, Tenn.—City Taxicab Company; capital, $3,500; to operate taxicabs. Incorporators: E. D. Dakin, T. O. Perkins, J. D. Andrews, W. V. Andrews, F. M. Swann.

New York City.—Automobile Importers Alliance; capital, $750; to look after the interests of automobile importers. Incorporators: George J. Ginsburg, Bernard C. Wyner.

New York City.—Protective Auto League Company; capital, $1,000. Incorporators: I. Fogg, D. G. Hopkins, G. W. Dillman.

New York City.—Wadsworth Garage, Inc.; capital, $9,000; to conduct a garage. Incorporators: William Daly, Albert C. Christian, George A. Boyd.

Paterson, N. J.—Paterson & New York Motor Express Company; capital, $50,000; to conduct a general transfer and express business. Incorporators: J. M. Simpson, M. Brooks, H. Smith.

Racine, Wis.—Faultless Starter Company; capital, $10,000; to manufacture a self-starter. Incorporators: D. I. Shoop, Samuel Hansen, Morton Walker, J. Barker.

St. Louis, Mo.—Pugh Auto Chain Company; capital, $5,000; to manufacture and deal in automobile chains. Incorporators: John Schulz, Webster Groves, Arville A. Van Cleave, Edward Brockschnitt.

Trenton, N. J.—M. & M. Tire Company; capital, $20,000; to manufacture rubber goods and tires. Incorporators: William McGinnis, Edgar W. Greene, Walter A. Wood.

Washington, D. C.—Automobile Engineering College; capital, $5,000; to educate chauffeurs. Incorporators: Frank N. Justice, Edgar L. Turner, Thomas W. Smithfield, Garfield H. Street.

CHANGES OF NAME AND CAPITAL

Cleveland, O.—Cleveland Auto Starter Company; capital increased from $25,000 to $50,000.

Detroit, Mich.—English Company; capital increased from $5,000 to $100,000.

Monroe, Mich.—Elkhart Manufacturing Company; capital increased from $60,000 to $110,000.

Racine, Wis.—Racine Rubber Company; changed name to Belle City Rubber Company.

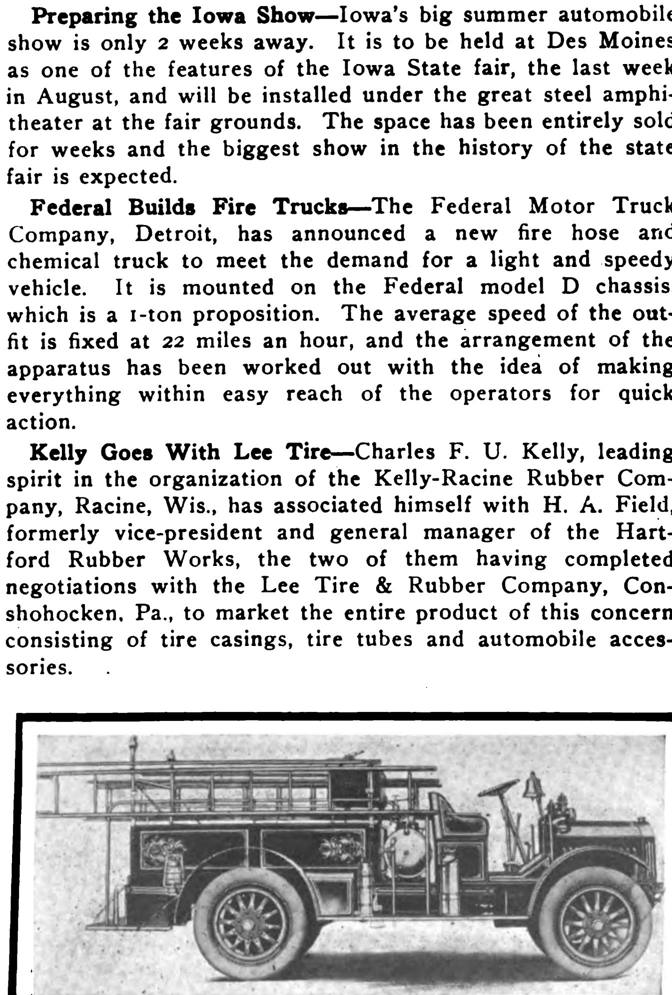
Hall Now Olds Sales Manager—J. V. Hall, formerly manager of the Oldsmobile Company, of Illinois, has been appointed general sales manager of the Olds Motor Works, of Lansing, Mich., to succeed R. E. Paris, resigned. Mr. Hall will assume his duties at Lansing on September 1.

Oakland Sales Branch in Detroit—The Oakland Motor Car Company, Pontiac, Mich., has opened a sales branch in Detroit with William R. Tracy, for the past two seasons sales manager of the Oakland Sales Company, Ltd., as its manager. J. F. Montgomery has resigned from the Bemb-Robinson Company to take a sales position with this new firm.

Preparing the Iowa Show—Iowa's big summer automobile show is only 2 weeks away. It is to be held at Des Moines as one of the features of the Iowa State fair, the last week in August, and will be installed under the great steel amphitheater at the fair grounds. The space has been entirely sold for weeks and the biggest show in the history of the state fair is expected.

Federal Builds Fire Trucks—The Federal Motor Truck Company, Detroit, has announced a new fire hose and chemical truck to meet the demand for a light and speedy vehicle. It is mounted on the Federal model D chassis, which is a 1-ton proposition. The average speed of the outfit is fixed at 22 miles an hour, and the arrangement of the apparatus has been worked out with the idea of making everything within easy reach of the operators for quick action.

Kelly Goes With Lee Tire—Charles F. U. Kelly, leading spirit in the organization of the Kelly-Racine Rubber Company, Racine, Wis., has associated himself with H. A. Field, formerly vice-president and general manager of the Hartford Rubber Works, the two of them having completed negotiations with the Lee Tire & Rubber Company, Conshohocken, Pa., to market the entire product of this concern consisting of tire casings, tire tubes and automobile accessories.



Kelly chemical wagon loaned to the Springfield, O., fire department

Factory Miscellany

Plant of the Keeton Motor Company, at Wyandotte, Mich., to be devoted to the making of six-cylinder cars

Keeton Buys Seitz Factory—The plant of the Seitz Automobile & Transmission Company, Wyandotte, Mich., has been acquired by the Keeton Motor Company. The building, which is shown on this page, will be equipped by the purchaser for the manufacture of six-cylinder cars.

Austin to Build Factory—The Austin Automobile Company, Grand Rapids, Mich., has bought 6 acres of land upon which it will soon erect a factory.

Kisselkar Plant Being Increased—The Kissel Motor Car Company, Hartford, Wis., has just begun the erection of an addition to its automobile factory.

Chalmers to Add to Plant—An addition to the Chalmers factory is being planned, which is to enable the company to cope with the growing demand of cars.

Longstreth Company Negotiating for Plant—The Longstreth Motor Car Company, Philadelphia, Pa., has opened negotiations for a building at 2126 Market street.

Canadian Factory Being Built—A contract for the construction of an Amherst, N. S., factory of the Nova Scotia Carriage & Motor Company has been awarded to a firm of contractors of that town.

Stewart Iron Works Resurrection—The burned-down plant of the Stewart Iron Works Company, Cincinnati, O., which was recently destroyed by fire, will be replaced by a new structure having 100 by 415 feet floor space.

Toronto Gets New Factory—A new factory for Toronto, Ont., will be erected in the near future by the Russell Motor Car Company on North Keele street. The building will be of reinforced concrete and cost approximately $75,000.

Parr Company Buys Land—The Parr Wagon Company, South Greensburg, Pa., has bought 3 acres of land on which stands a large factory building. The company will soon begin to manufacture trucks and automobiles in the new plant.

Clark Brothers Rebuild Plant—Clark Brothers, whose factory at Belmont, N. Y., was burned recently, have completed their plans for the erection of a new factory which will comprise two steel-and-concrete structures covering 100 by 300 feet each.

Buick Plant Bought by Jackson—The Jackson Automobile Company, Jackson, Mich., is said to have acquired the plant of the Buick Motor Company located in that city. This deal places the Jackson concern in the possession of two modern factories in the same city.

Corcoran to Manufacture Accessories—The manufacture of tools and accessories is the object of the Corcoran Manufacturing Company, Cincinnati, O. The company has leased a five-story plant at Second and Elm streets, which will soon be equipped so that manufacturing operation may be started.

Overland Factory Is Improved—Improvements, the cost of which aggregates about $45,000, were begun last week in the Willys-Overland Company's plant at Toledo, O. The changes comprise a new blacksmith shop and an addition to the repair shop. The A. Bentley & Sons Company has received the contract for the work.

Leech Company Will Manufacture—A new type of gasoline engine will soon be manufactured by the Leech Automobile Company, Lima, O., a newly founded $100,000 corporation.

Long Has Factory Constructed—The contracts for the erection of a $50,000 factory of automobile parts has been given out by the Long Manufacturing Company, Detroit, Mich.

Lumen Factory Being Enlarged—An addition to the factory of the Lumen Bearing Company, Buffalo, N. Y., is under way. The company at present has a manufacturing floor space of 70,000 square feet and the addition now planned will comprise a two-story machine shop, which will make the firm's plant one of the largest establishments of its kind in this country.

Minneapolis Republic Company Will Build—The Republic Motor Company, of Minneapolis, Minn., has secured a site for a factory building to be erected in the near future.

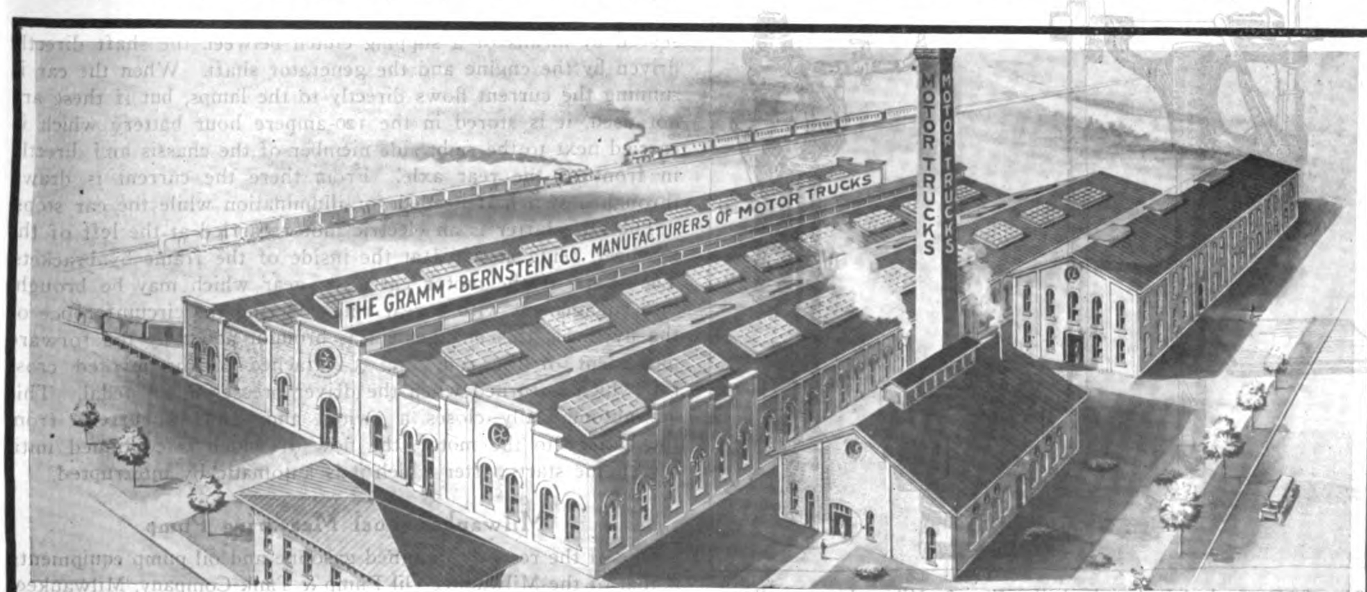
Geneva Supply Factory Building—Karlsene & Skarin, Geneva, Ill., are getting ready to construct a factory building, 50 by 65 feet, where automobile supplies will be manufactured.

Ford Minneapolis Plant Being Rushed—Kees & Colburn, the Minneapolis architects who have received the contract for the erection of a factory of the Ford Motor Company, are making haste in preparing the plans for this work.

Cutting Factory Increases Capacity—The Clark-Carter Automobile Company, Jackson, Mich., has now almost completed a four-story addition to its present plant, which will enable it to considerably increase its output for 1913.

Harris to Build Wheels—The mill building at the junction of Union street and Payson avenue, Easthampton, Mass., owned by Dibble & Warner, has been purchased by Charles Harris, who is to use it in which to manufacture automobile wheels.

Fitchburg Seeks Durant's Factory—R. D. Redfern, industrial secretary of the Fitchburg, Mass., Board of Trade, has got into communication with W. C. Durant, who is the head of the Republic Motor Company, and has made him an offer to establish one of the company's plants in that city.



New plant of the Gramm-Bernstein Company which makes motor trucks, at Lima, Ohio

Electric Bench Drill; Explosion-Proof Garage Heater; Powerful Self-Starter; Gasoline Equipment; Economic Electric Headlight; Rear View Mirror; Floorboard Material; Spring Shock Absorber; Lamp Lighter; Enriches Gasoline

Deer Electric Bench Drill

AN electric bench drill having an 8 1-4 by 10 1-2 table is made by the A. J. Deer Company, Hornell, N. Y. The drill, Fig. 1, is a simple design and all its moving parts are made of high-speed tool steel. The vertical movement of the drilling spindle is 2 1-4 inches and the space of vertical adjustment of the table 8 3-4 inches. From the center of the spindle to the column it is 5 1-4 inches, and from chuck to table 8 3-4 inches. The drill capacity of the machine is 1-4 inch. It may be operated at five different speeds, being driven by either an alternating or direct-current motor using 110-220 volt current. The net weight of the drill without the motor is 120 pounds.

Scientific Garage Heater

The Scientific Heater Company, 2123 East Second street, Cleveland, O., manufactures a small and safe garage heater which, when once lighted, serves an establishment throughout a season without requiring any further care. The device, Fig. 7, is square in shape, 39 inches long, 38 inches high and 12 1-2 inches wide; it is preferably attached to the wall and can be located at any suitable height. The fuel for the garage heater is city gas or natural gas. To start the heater the fire door, so-called, is opened and a match applied to pilot light. Then the fire door is closed and by turning a valve the gas is admitted to the burner, where it is ignited. The necessary air is now drawn in through a close wire-mesh screen which insures the safety of the lamp in the same way as it guarantees that of a Davy lamp used by miners.

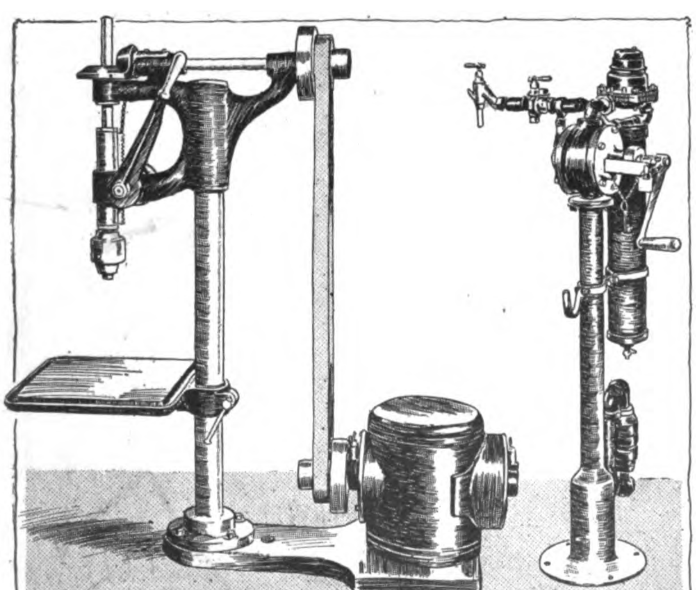


Fig. 1—Deer electric bench drill. Fig. 2—Milwaukee gasoline measuring pump

Peerless Electric Self-Starter

The Peerless Motor Car Company, Cleveland, O., is equipping its 1913 product with a complete electric starting and lighting system made by Gray & Davis, Boston, Mass. The lighting generator of this system, which also produces the current used afterward for starting the engine, is mounted adjacent to the engine and is driven therefrom at constant speed which is pre-

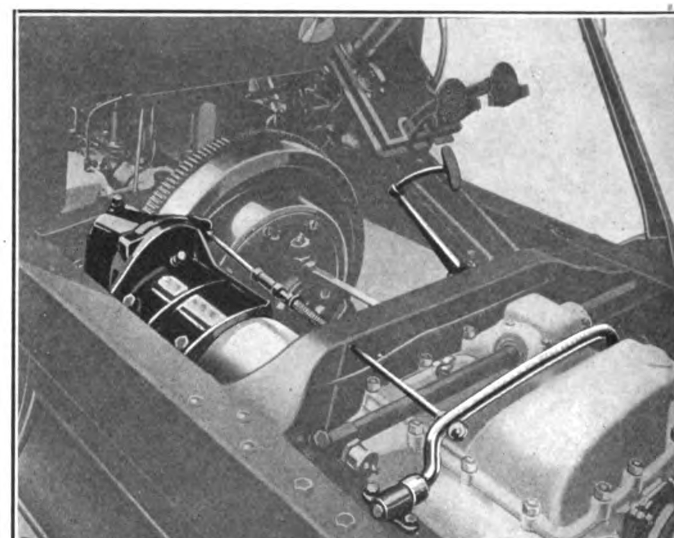

Fig. 3—Gray & Davis self-starter with which 1913 Peerless cars are fitted

served by means of a slipping clutch between the shaft directly driven by the engine and the generator shaft. When the car is running the current flows directly to the lamps, but if these are not used, it is stored in the 120-ampere hour battery which is carried next to the right side member of the chassis and directly in front of the rear axle. From there the current is drawn through a switch if needed for illumination while the car stops.

The self-starter is an electric motor carried at the left of the flywheel, being attached at the inside of the frame by brackets. The shaft of the motor carries a gear which may be brought into engagement with a gear ring covering the circumference of the flywheel; this engagement is brought about by the forward movement of the rod, Fig. 3, attached to the pivoted cross rail which is turned when the driver presses down pedal. This act automatically closes a switch and sends a current from the battery to the motor, the flow of which is continued until the engine starts, after which it is automatically interrupted.

Milwaukee Fuel Measuring Pump

One of the recently designed gasoline and oil pump equipments is that of the Milwaukee Oil Pump & Tank Company, Milwaukee, Wis., Fig. 2. This outfit consists of a measuring pump and a tank; the pump is of the plunger type, but no leather washers or valves are used inside the pump cylinder. All the working parts are made of bronze. The pump may also be used for the handling of thick liquids such as varnish; it is furnished with a seamless steel tank. Furthermore the equipment ordinarily includes a filter, meter and nozzle, which, however, may be omitted if the purchaser so desires.

New Automobile Mazda Lamp

The General Electric Company, Schenectady, N. Y., has just put on the market a new type of Mazda lamp specially designed for automobile headlights. This lamp, Fig. 4, has a tungsten filament formed in a coil without an anchor, making it very compact and strong and sending out all the light from a very small space, so that the total volume of rays may be brought into the focus of a parabolic lamp. The lamp is made in sizes ranging from 9 to 24 candlepower. It is claimed that this lamp gives over twice as much light as a carbon lamp consuming the same amount of current.

The Eclipse Rear View Mirror

A new model of the Eclipse rear view mirror, made by the Eclipse Specialty Company, 250 West Fifty-fourth street, New York City, is shown in Fig. 5. While the shape and appearance of the mirror remain the same as formerly, the method of attachment has been modified and improved. Instead of using the ball-and-socket joint of the old model, the new type uses a bracket which is clamped by a thumb screw to a horizontal rod which is turnable around its axis and around the vertical support to which it is attached. The mirror comes in brass, nickel and black finish.

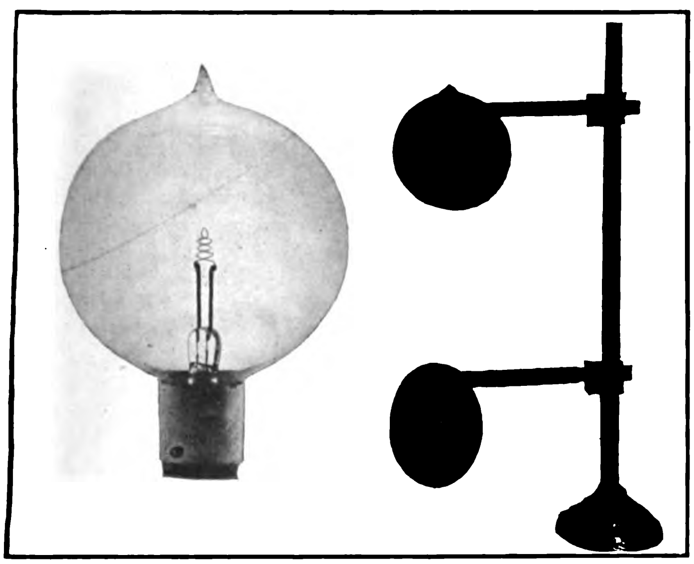

Fig. 4—G. E. Mazda automobile headlight. Fig. 5—Eclipse rear-view mirror

Acetrol Fuel Enriching Mixture

Utilizing the solubility of acetylene in acetone, which is used in filling gas tanks, the Acetrol Manufacturing Company, Milwaukee, Wis., has put on the market a mixture which is said to considerably increase the fuel value of gasoline, if 1 pint of it is mixed with about 16 gallons of gasoline.

Goodnow Gasoline Tank Gauge

A gasoline gauge of the stick type is being marketed by the Goodnow Manufacturing Company, 754 Old South Building, Boston, Mass. The gauge is a black stick of square section, upon which twenty brass markers are slidably arranged. Each marker carries a number, ranging from 1 to 20, and by filling the gasoline in a tank gallon by gallon and adjusting the gauge to the varying level of the fuel in the tank, the gauge may be used for any shape of container, be it square, oval or irregular. The gauge is also made with thirty markers for the use in connection with specially deep tanks.

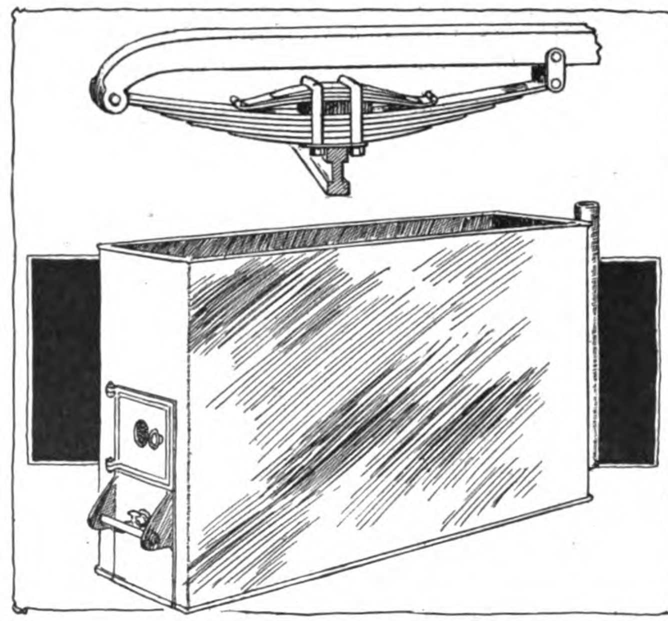

Fig. 6—Amos spring shock absorber. Fig. 7—Scientific safety garage heater

Corubia Acetylene Lamp Lighter

To light acetylene lamps without the use of matches or batteries and spark coils, the Corubia Manufacturing Company, 71 Third avenue, New York City, now makes a small burner to which a self-lighting device is attached. The latter consists of a stem in the top of which a hard-steel gear is pivoted which is in contact with the lava arm of the burner. The lower end of the stem carries a round plate and the steel gear is held in its highest possible position by the tension of a small spring wound around the above-mentioned stem. If the plate at the end of the stem is pressed downward, the friction between steel and lava results in a series of sparks which are directed in the center of the burner space, where they ignite the acetylene coming from the tank. When the plate is released the steel gear returns again to its normal position and is then ready for the next application

Ames Leaf-Spring Shock Absorber

To check the rebound of the lower leaves of elliptic springs the Ames shock absorber, made by O. B. Ames, Brewster, N. Y., has been designed. It consists of a small three-leaf spring attached to the elliptic spring by a double U-clip, Fig. 6; a rubber cushion is inserted between the two springs. This arrangement does not limit the free movement of the main spring as long as only moderate road inequalities are encountered but when the car strikes a bump or thank-you-ma'am the small spring counteracts the excessive movement of the large one as well as its sudden rebound, thereby adding to the life of the spring proper.

Adamat Composition Floorboard

The Flintkote Mfg. Co., New York City, maker of waterproofing specialties, is now in the market with a new product, Adamat, which is a composition flooring material. It consists of a water and fireproof body which is covered, on both sides, with a comparatively thick, rubber-like skin. The material does not absorb or permit the passage through it of a drop of moisture and is claimed to be unaffected by ordinary gases and fumes. Since both sides are prepared with the same finish and color, the material may be turned around when one side is worn. Adamat is made in red and black, coming in 36- and 72-inch width in the red material, and 36 inches in the black one.

FENDER for Motor Vehicles—Being a design on which the fender is turned when the front wheels are moved laterally by the steering gear action.

This patent refers to the construction of a fender, Fig. 3. Brackets are clamped to the steering gear and have longitudinally slotted standards rotatably fastened to them. To the standards a fender is secured projecting beyond the wheel.

No. 1,033,750—to Albertus Tift, Deer Harbor, Wash. Granted July 23, 1912; filed August 8, 1911.

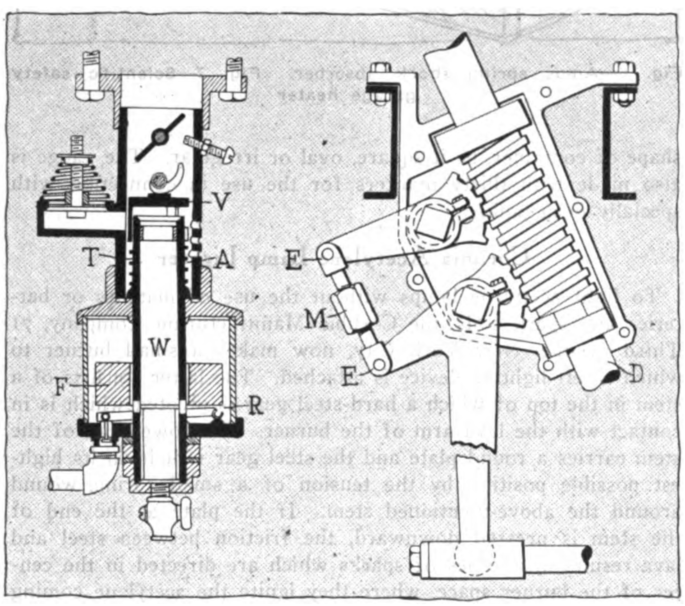

Fig. 1—Morris-Merritt wick-feed carbureter. Fig. 2—Moore steering gear

Lock Nut—Being the combination of a nut and lock washer, which latter is a resilient plate.

The lock washer W., Fig. 4, is a resilient plate, folded around a nut, with three parallel corrugations; it has rounded channels and crests permitting the corrugations to yield under pressure, thereby securing a lateral sliding action which is accompanied by a spring resistance between the washer and the parts between which it is clamped. The intermediate corrugations have a bolt opening with an inward lug adapted to engage a bolt groove G.

No. 1,033,759—to Granville A. Humason, Shreveport, La. Granted July 23, 1912; filed April 26, 1910.

Shock Absorber and Spring—A design combining the functions of these two members, which is held to axle and body.

In Fig. 5 is shown the subject-matter of this patent, which comprises upper and lower spring-retaining plates P1 and P2 plates and an intermediate body-retaining plate B, between which springs are positioned in the following manner: The plates have on their edges annular flanges which serve to brace and strengthen them and are connected by bolts C. Spring-receiving sockets S are arranged on the plates around the bolts, and coiled springs surround the bolts.

No. 1,033,657—to Julian Seay Bashaw, Gainesville, Fla. Granted July 23, 1912; filed April 11, 1911.

Wick-Feed Carbureter—In which the normal air intake surrounds a wick the end of which is submerged in the fuel.

The subject-matter of this patent, a wick-feed carbureter, is shown in Fig. 1; it consists of a fuel reservoir R containing a float F for controlling the admission of fuel thereto. Above the reservoir an air chamber A with air openings is placed, and a vertical tube T is so stationed that its upper, open end is within the air chamber, while the lower end is in the reservoir R. A wick W is located in the tube T, and its lower end is immersed in the fuel in R, the upper end being in the chamber A and tube is adapted to be closed by a valve V.

No. 1,033,443—to Charles A. Morris and Walter H. Merritt, Red Bank, N. J. Granted July 23, 1912; filed March 27, 1911.

Steering Gear Mechanism—In which two or more gears or sections engage the steering worm.

This patent refers to a steering gear, Fig. 5, consisting of a worm D which is engaged by two or more pivotally mounted members D, which may be of the gear or sector type. These members engage the worm oppositely at different threads.

No. 1,033,442—to Van Zandt M. Moore, Cleveland, O. Granted July 23, 1912; filed March 15, 1911.

Vol. XXVII NEW YORK—THURSDAY, AUGUST 15, 1912—CHICAGO No. 7

The AUTOMOBILE

Dyer Licenses To Be Taken Out By Automobile Board of Trade

Present and Future Membership of Manufacturers' Organization Provided for Up to Certain Limit Under Lump Sum Agreement—Board Will Turn Over the Minor Patents

Suits Now Pending Against Members to Be Withdrawn When Licenses Are Issued—Negotiations Have Been Pending for 6 Months—Patent Runs 13 Years

CONSEQUENT upon negotiations extending over a period of more than 6 months, the Automobile Board of Trade and the Enterprize Automobile Company have finally reached an agreement.

Manufacturing licenses under the Dyer patents, covering selective transmission, and direct drive epicyclic transmission, also known as planetary, the right to use the H change-plate and other devices covered by the patents, has been secured for a certain number of the present and future members of the Automobile Board of Trade, under an agreement dated August 15, 1912. The contract securing these rights is voluminous, but its exact terms have not been made public.

Under the contract the Board of Trade pays a lump sum to the Enterprize Automobile Company, of Hoboken, N. J., the holding corporation that owns the Dyer patents and secures the right from the Enterprize company to apply for licenses for its membership without cost up to a certain specified number. It is also provided that in case the individually licensed company leaves the Automobile Board of Trade or abandons manufacturing, the license shall expire. In the contingency of the dissolution of the Board of Trade, the agreement, as such, will be nullified. Just what will be done with applications for license in excess of the specified number was not revealed by either side.

As a further consideration for the contract it is provided that the Patents Holding Association, a subsidiary of the old Association of Licensed Automobile Manufacturers and which was inherited by the Automobile Board of Trade, shall convey all right, title and interest held by it in the five Dyer patents covering the H-change-plate, removable rigid motor frame, planetary gear and other gear patents, to the Enterprize Automobile Company and that the licenses issued by the Enterprize Automobile Company shall include rights to manufacture under all the patents involved in the settlement and any further automobile patents that may be taken out by Leonard H. Dyer.

The rights of the Patents Holding Association consisted of exclusive rights to issue licenses under the five minor patents referred to. These rights have been held by the association for over 6 years.

The Enterprize company is left free to grant licenses to other manufacturers on a royalty basis.

The rights secured to the members of the Automobile Board of Trade are very broad.

The most important patent included in the license rights attained under the agreement is number 885,986, a division of the application filed by Leonard H. Dyer, February 3, 1900. This patent is remarkably broad in its view and is outlined in fifty-seven separate claims. It is dated April 28, 1908, and consequently will run until April 28, 1925, a trifle less than 13 years.

The Enterprize Automobile Company has issued two manufacturing licenses so far. One was to the makers of the Correja and the other to the manufacturers of the G. J. G. Three importers' licenses have been granted and over eighty individual licenses.

Suit was commenced against four companies affiliated with the Automobile Board of Trade last year and the minor suits were pressed, according to Mr. Dyer, to demonstrate what basis of

The five Dyer patents which have been assigned to the Enterprize Automobile Company by the Automobile Board of Trade, all apply to improvements in the gearing for automobiles. They are numbered respectively, 643,595, 657,650, 662,400, 662,401 and 676,223.

The first of them was applied for June 8, 1898, and was granted September 11, 1900, and covers a fixed guide plate with recesses and notches to hold the gear-shifting lever. This is patent No. 657,650.

Patent 643,595, granted February 13, 1900, is for two gears and an intermediate epicyclic gearing interposed between one of the gears and the driven axle.

Patent 662,400, granted November 27, 1900, covers the subject of two shafts with spur gearing and means for intermeshing the gear wheels so as to transmit power from the driving to the driven shaft.

Patent 662,401 is for a multiple-speed transmission gearing, and similar to the main patent, save that the gears cannot be shifted as an entirety and the principle of direct drive with all gearing quiescent is not covered.

Patent 676,223 covers a removable ridged bridge to carry the motor and operating parts.

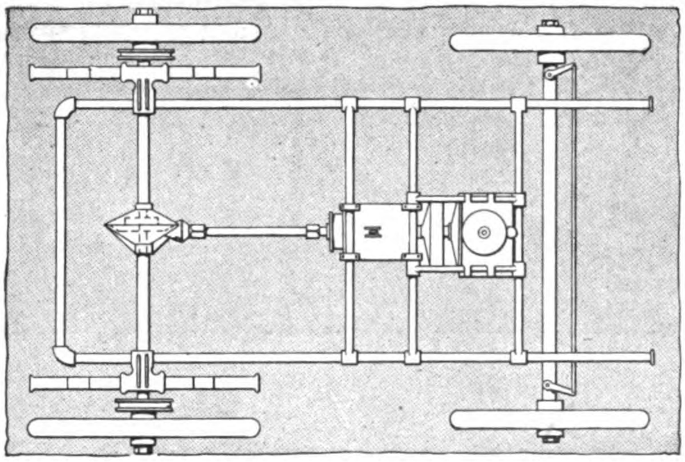

Fig. 2—Showing location of Dyer's device from above

royalty should be charged pending the determination of the main suits.

This campaign will probably be continued for a time despite the withdrawal of the main suits in question as soon as licenses have been issued to the defendant companies.

According to William A. Redding, patent counsel, associated with Frederick P. Fish, in representing the Automobile Board of Trade, the Dyer transmission patent is broader and more intimately related to the automobile trade than the Selden patent was deemed to be. The devices described by Mr. Dyer in patent 885,986 cover the selective type of transmission in fifty-seven phases, and Mr. Redding declares that the present type of selective transmission in general use throughout the industry comes within the terms of the patent.

The full text of the claims made by Mr. Dyer is reproduced on another page.

The effect of the agreement will be to check prosecutions for infringement against the licensed members of the Automobile Board of Trade and the sellers and users of their product. The four suits now pending against the Maxwell-Briscoe Motor Company, Locomobile Company, of America, Winton Motor Carriage Company and the Saurer manufacturers will be withdrawn when licenses have been granted to the four companies.

These suits were entered last summer and fall on behalf of the Enterprize Automobile Company as assignee of the patent rights of Leonard H. Dyer. They called upon the court to grant an injunction against further infringement and asked for an accounting for profits derived from past infringement and damages for the alleged infringements.

In discussing the litigation, Mr. Redding said:

"The suits have been in the United States District Court, Southern District of New York, for about a year. Even before the filing of the formal actions we had begun a systematic search of the prior art. At a cost of thousands of dollars the United States Patent Office, and the similar institutions of Switzerland, Germany, France, Belgium, Italy and Great Britain were thoroughly examined. Time and money was spent in profusion to make the search radical and comprehensive and I can say that in the 38 years during which I have handled patent matters, none has come under my notice in which more care was used or more pains exerted.

Redding Describes Breadth of Patent

The patent is imposing in its breadth and has been a threatening element in the industry up to this time. Our search disclosed a mass of data, but the industry can draw its own conclusions from the fact that my clients were strongly advised by me, as early as last winter, to take out licenses and avoid the possible danger and expense that must have followed a complete and favorable adjudication of the patents in question.

"Since that period, numerous conferences have been held between the interested parties and an option was given by the Enterprize Automobile Company to take out licenses. This option would have expired August 15. I am not at liberty to detail the terms of the instrument nor the particulars of the agreement we have just made. There were some changes in the original proposition submitted on behalf of the Enterprize company and some changes in the counter-proposition made by my clients to the Enterprize company, but I can say that the agreement is satisfactory to both sides. It raises the shadow cast by the likelihood of suits against makers and users of automobiles produced by the Automobile Board of Trade members and gives them certain valuable rights under the patents and at the same time the acknowledgment of the validity of the patents by the act of taking licenses under them must prove agreeable to the patentee and his assigns."

It was stated by Mr. Redding that his efforts had been directed solely toward bringing about the present settlement ever since the search conducted under his direction for devices anticipating the Dyer patents had been concluded. His answer, a most voluminous document, has been finished for nearly 6 months, and while it was never filed, due notice of its readiness had been served upon the complainants. Numerous continuances have marked the progress of the suits on motion of Mr. Redding.

The Enterprize company consented to these delays so that the negotiations for settlement might be pursued. These stipulations granted extensions of time to file the answer and were renewed regularly, rule day after rule day.

The contract for licenses under the lump sum agreement provides for the present membership of the Automobile Board of Trade if applications are made and all companies that join that organization in the future up to a certain number. As a merger of the Automobile Board of Trade and the National Association of Automobile Manufacturers is pending, the members of the National Association, who are not already members of the Board of Trade, will be entitled to licenses on that basis.

The procedure by which the licenses will be granted contemplates an application by the Board of Trade to the Enterprize Automobile Company for such license. The number is not limited, but it is unquestionably true that future members of the Board of Trade will have to pay more for the license privilege than the present membership, including the N. A. A. M.

Eligible to License Under Agreement

The present membership of the Automobile Board of Trade is as follows:

Autocar Company, Buick Motor Company, Cadillac Motor Car Company, Cartercar Company, Chalmers Motor Company, Jas. Cunningham Sons and Company, Elmore Manufacturing Company, H. H. Franklin Manufacturing Company, Garford Company, Haynes Automobile Company, Hudson Motor Car Company, International Motor Company, Jackson Automobile Company, Knox Automobile Company, Locomobile Company, of America, Lozier Motor Company, Marquette Motor Company, Matheson Automobile Company, Mercer Automobile Company, Metzger Motor Car Company, Mitchell-Lewis Motor Company, Moline Automobile Company, Moon Motor Car Company, National Motor Vehicle Company, Nordyke and Marmon Company, Oakland Motor Car Company, Olds Motor Works, Packard Motor Car Company, Peerless Motor Car Company, Pierce-Arrow Motor Car Company, Pope Manufacturing Company, Premier Motor Manufacturing Company, Pullman Motor Car Company, Rapid Motor Vehicle Company, Reliance Motor Truck Company, Reo Motor Car Company, Selden Motor Vehicle Company, F. B. Stearns Company, Stevens-Duryea Company, S. G. V. Company, E. R. Thomas Motor Company, United States Motor Company, Warren Motor Car Company, White Company, Willys-Overland Company, Winton Motor Carriage Company.

The list totals forty-six. In the event of application for license of the constituent companies of the United States Motor Company and the International Motor Company, this number would be increased to fifty-one.

The full roster of the N. A. A. M. includes the following cars:

Auburn, Abbott, Alco, American, Detroit, Electric, Apperson, Austin, Autocar, Babcock electric, Baker, Glide, Brush, Buick, Cadillac, Cartercar, Chalmers, Cutting, Cole, Columbia, Firestone-Columbus, Corbin, Stoddard-Dayton, De Tamble, Duryea, Elmore, E-M-F, Federal truck, Fiat, Ford, Franklin, Garford, Grabowsky, Gramm, Great Western, Haynes, Hewitt, Hudson, Hupmobile, Imperial, Interstate, Jackson, Rambler, Kelly truck, Kissel, Knox, Krit, Locomobile, Lozier, Stutz, International Motor Car Manufacturing Company, Marquette, Matheson, Maxwell, Everitt, Mitchell, Moline, Moon, National, Marmon, Oakland, Ohio electric, Oldsmobile, Packard, Peerless, Pierce-Arrow, Case, Pope, Premier, Pullman, R. C. H., Rapid, Rauch and Lang, Regal. Reliance, Reo, Royal Tourist, Selden, Simplex, Staver, Stearns, Stevens-Duryea, Studebaker, Thomas, Velie, Walter, Waverley, White, Winton, Woods, Overland, Warner. This makes a total of ninety-two members.

There are forty-four members of the N. A. M. who are not represented in the Board of Trade, but among them are six makers of electrics, a duplication of the Studebaker Corporation and E-M-F and several companies that are not active at the moment. The United States Motor Company, comprising the Brush, Maxwell, Columbia, Stoddard-Dayton and Sampson lines is expected to take out four licenses for the last four companies named. This will bring the total number of licenses to be granted to the members of the merged organizations about seventy-five.

In the list of members are the names of several companies whose product is deemed to be outside the patents. Precisely which companies are included in this list will appear when the licenses are granted.

One Reason for Merger Disclosed

The outcome of the successful negotiations uncovers one of of the main reasons for the pending merging between the two national organizations. The membership of the Board of Trade is almost entirely included in the National association, but the National Association under its charter is not allowed to hold patent rights as such. Therefore, if the license rights are assumed by the Automobile Board of Trade and the two organizations are merged, the members of the National Association will be able to enjoy the privilege of license rights granted through the Board of Trade.

An interesting sidelight on the matter is shed by a statement made to THE AUTOMOBILE by Herman Cuntz, patent counsel for the Board of Trade. Mr. Cuntz returned from a trip abroad recently, having been commissioned to conclude negotiations between the General Vehicle Company and the Daimler company for the exclusive American rights to manufacture Daimler commercial vehicles by the former company. Trucks of this type use a selective type of transmission under British patents dated in 1898. Mr. Cuntz was asked whether this device did not anticipate the Dyer patents in such a way as to defeat them; he replied in the negative, saying that there were vital points of difference between the Daimler patented device and that covered by the Dyer patents. The chief point, he said, was that the Dyer device is shiftable as an entirety, while that employed since 1899 in the Daimler commercial wagons constitutes a series of shifts in order to vary speed and reverse. Mr. Cuntz characterized the later improvements now used in the Mercedes and Daimler pleasure automobiles as changes and modifications of the original idea.

The main Dyer patent in the limelight at present is number 885,986, issued April 28, 1908, on application filed January 22, 1906, but in reality extending back in its effect to the statutory period before February 3, 1900. The reason for this retroactive effect of the patent is that it is declared to be a division of an application for patent filed at that date by Leonard H. Dyer and which was later issued as patent 921,963 under date of May 18, 1909.

Patent 921,963 underlies the other as a sort of foundation for it. It is for an automobile vehicle, covering improvements in the frame, driving gear and changing and reversing mechanisms. According to the language of the patent, the object of the invention is to improve automobile construction by direct driving connections between the motor and the differential with such reduction as is necessary owing to the relatively different speeds of such parts. In connection with this direct drive mechanism is provided an additional low speed gearing, and if necessary, a back or reverse gearing, either of which will be introduced when required.

The invention also comprises in a rectangular metal framework, supported by means of springs, upon wheels with a driving motor carried thereon. Connection is made between the driving engine and the longitudinal shaft by means of the usual friction clutch and the shaft may be provided if necessary with one or more flexible or knuckle joints to permit the framework to oscillate independently of the wheels and yet allow the driving mechanism to run freely.

What Underlying Patent Contains

To provide a speed-changing gear the longtitudinal shaft is formed in two parts with a releasable connection between, combined with means for rotating the two shaft parts at different speeds. The invention is broad enough to permit of any form of mechanism being used for this purpose, but an auxiliary is preferred, so mounted as to be parallel with the two parts of the main shaft, with a system of spur-gearing, which is normally not in mesh but which can be inter-meshed after the two shaft parts have been separated.

Combined with the speed reducing gear is a reversing gear, which may be of any type but a series of gears mounted upon another auxilliary shaft with bevel gearing so arranged that the two parts of the longitudinal shaft may be caused to rotate in opposite directions is preferred.

The claims under this patent number three and are as follows:

1—The combination in a vehicle of a spring-supported frame, driving and steering wheels, a motor mounted upon the front of the frame, a shaft driven by such motor and in line with the shaft of the motor, the said shaft being longitudinally arranged substantially at an equal distance between the wheels and substantially parallel with the ground, a friction clutch connecting the shaft to the motor, a second shaft in line with the first shaft, means for directly connecting the two shafts for driving the second shaft without reduction in speed, means for breaking the connection between the two shafts and for connecting them together through power transmitting mechanism, affording a reduced speed, a differential gear between the second shaft and the wheels of the vehicle, and a reversing gear for reversing the direction of travel of the vehicle.

2—The combination in a vehicle of a spring supported frame, driving and steering wheels, a motor mounted upon the front of the frame, a shaft driven by such motor and in line with the shaft of such motor, the said shaft being longitudinally arranged between the wheels, a friction clutch connecting the shaft to the motor, a second shaft in line with the first shaft, means for directly connecting the two shafts for driving the second shaft without reduction in speed, and means for breaking the connecting between the two shafts and for connecting them together through power-transmitting mechanism, affording a reduced speed.

3—The combination in a vehicle, of a spring supported frame, driving and steering wheels, a motor mounted upon the front of the frame, a shaft driven by such motor and in line with the shaft of the motor, the said shaft being longitudinally arranged between the wheels, a friction clutch connecting the shaft with the motor, a second shaft in line with the first shaft, means for directly connecting the two shafts for driving the second shaft without reduction of speed, means for breaking the connection between the two shafts and for connecting them together through power-transmission mechanism, affording a reduced speed, and a reversing gear for reversing the direction of travel of the vehicle.

Referring to the accompanying illustrations designated as

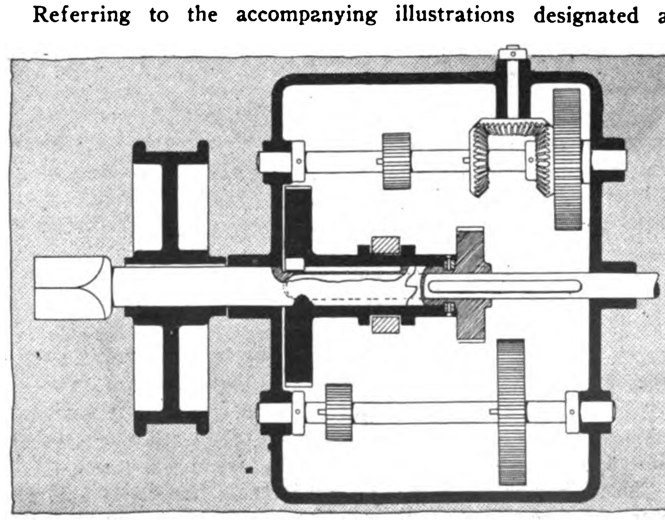

Fig. 3—Low speed and reversing gear claimed in patent

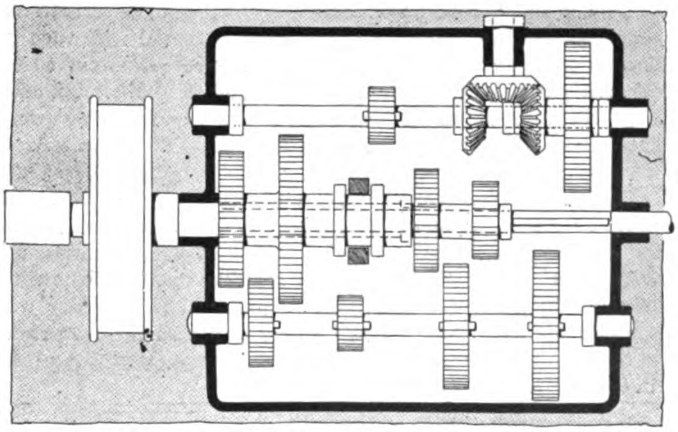

Fig. 5—Low and reverse with additional forward speeds

Figures 2, 3, 5, 6 and 7 and taken from the official drawings shown in the patent papers, Fig. 2 shows the location of the patented device, looking down upon a motor vehicle chassis; Fig. 3 shows the low speed and reversing gears; Fig. 5 shows the low, reverse and additional forward speeds secured by the addition of extra secondary gears upon one of the auxiliary shafts together with extra gears on the main driving shaft. Figs. 6 and 7 are views of the device from above and from one end.

The claims of patent 885,986 are as follows:

1—In a transmission for automobiles, the combination of a driving member, a driven member, a driving gear for the former, a plurality of intermediate gears, including a reversing gear and means, including mechanism shiftable as an entirety for driving said driven member through any one of said intermediate gears.

2—In a transmission gear for automobiles, the combination of a driving member, a driven member, a driving gear for the former, a plurality of intermediate gears including a reversing gear and means, including mechanism shiftable as an entirety, for coupling said driving member to said driven member and for also driving said driven member through any one of the said intermediate gears.

3—Transmission mechanism for motor vehicles, the same comprising a driving member, a driven member, means to couple said driven member to said driving member to be driven by the latter and means comprising mechanism shiftable as an entirety to drive said driven member at a different speed for said driving member and to drive said driven member in reverse direction from said driving member.

4—Transmission mechanism for motor vehicles, the same comprising a driving member, a driven shaft axially aligned therewith, means to couple said member and shaft, one to the other for direct drive of the latter by the former, a plurality of gears arranged out of line with the axis of said shaft and driven by said member, and a shiftable transmission device on said shaft and adapted to engage the said plurality of gears to drive said shaft in the same, and also in a reverse direction.

5—In a transmission gear for automobiles, the combination of a driving member, a driven member, and means comprising mechanism shiftable as an entirety coupling said driving member to said driven member to drive the latter from the former and for varying the speed and direction of movement transmitted from said driving member to said driven member.

6—Transmission mechanism for automobiles, the same comprising a driving shaft, a plurality of fixed intermediate gears, including a reversing gear, means for supporting said gears, a driven shaft and means comprising a longitudinal, shiftable transmission device to rotate the latter from the driving shaft to any one of said intermediate gears.

7—Transmission mechanism for automobiles, same comprising a driving shaft, gear supporting means driven therefrom at a reduced speed, a plurality of fixed intermediate gears, including a reversing gear, a driven shaft and means comprising a longitudinal, shiftable transmission device to rotate the latter from the driving shaft through any one of said intermediate gears.

Claims Cover Shiftable Mechanism

8—TRANSMISSION mechanism for motor vehicles comprising a driving member, a driven member, a shiftable transmission member, means coordinate therewith to couple said driven member to said driving member, one or more stationary intermediate gears driven by said driving member and means to bring said transmission member into separate engagement and disengagement with said one or more intermediate gears.

9—Transmission mechanism comprising a driving member and a driven member adapted to be driven one by the other at the same speed, at different speeds, or in a reverse direction and mechanism longitudinally shiftable as an entirety for obtaining such changes in speed and direction.

10—Transmission mechanism for motor vehicle comprising a driving member, a driven shaft axially aligned therewith, a shiftable transmission device on said shaft, means for coupling said driving member and said driven shaft one to the other for the direct drive of the latter by the former, one or more stationary gears arranged at one side of the axis of said shaft and driven by said driving member and means to shift such transmission device into engagement with the said one or more gears.

11—In a motor vehicle, a motor, clutch, driving gear and driven shaft, all axially aligned, intermediate gears between said driven shaft and driving gear, mechanism shiftable as an entirety to couple said driven shaft to said driving gear and to drive said shaft from said driving gear through any one of said intermediate gears, a jack-shaft arranged at an angle with said driven shaft and driven therefrom and vehicle driving wheels connected with and driven from said jack-shaft.

12—In a motor vehicle, a motor, clutch, driving shaft and driven shaft, all axially aligned, means comprising mechanism shiftable as an entirety for varying the speed and direction of movement transmitted from said driving shaft to said driven shaft, a jack-shaft arranged at an angle with said driven shaft and driven therefrom and vehicle driving wheels connected with and driven from said jack-shaft.

13—In a transmission gear for automobiles the combination of a driving member, a driven member, axially aligned therewith and means comprising mechanism shiftable as an entirety to couple said driving and driven members together and to vary the speed and direction of movements transmitted from said driving member to said driven member.

14—In a speed changing gear for motor vehicles, the combination with a motor shaft, a driven shaft, means for connecting the two together to secure high speed, a low speed gearing consisting of a plurality of gear wheels caused to engage by longitudinal shifting movements and means for producing reverse rotation of the driven shaft.

15—In a motor vehicle the combination with the motor and driving wheels, of a gearing connecting the driving wheels and motors, the said gearing comprising a longitudinal shaft and a clutch connecting the shaft to the motor, and by means of which it will be driven, of means for rotating the wheels and a portion of the shaft at a different speed ratio, the said means including a jaw-clutch and longitudinally sliding gears, a single lever for sliding the gears and engaging and disengaging the jaw-clutch and a reverse gearing, and means operated by the said lever for engaging the reverse gearing.

16—In a motor vehicle the combination with a driving motor and driving wheels, of a gearing connecting the two, the said gearing comprising longitudinally aligned driving and driven shafts and a clutch connecting the driving shaft to the motor, and by means of which it will be driven, connections between the driven shaft and the driving wheels, gearing connecting the longitudinal shaft to positively drive the driven shaft at low or high speed, and comprising longitudinally sliding gears and a second clutch, and a single manually operated sliding device for sliding the gears, and for engaging the second clutch.

17—In a motor vehicle, the combination with a driving motor and driving wheels, of a gearing connecting the two, said gearing comprising longitudinally aligned driving and driven shafts and a clutch connecting the driving shaft to the motor and by means of which it will be driven, connections between the driven shaft and the driving wheels, gearing connecting the longitudinal shafts to positively drive the driven shaft at low or high speeds, and comprising longitudinally sliding gears and a second clutch, and a single actuating lever for sliding the gears and for engaging and disengaging the second clutch.

Gears Still When Disconnected

18—In a motor vehicle, the combination with the motor and driving wheels, of a gearing connecting the two, the said gearing comprising longitudinally aligned driving and driven shafts and a clutch for connecting the two, for driving the driven shaft at high speed, and reduced speed gearing for positively driving the driven shaft at a reduced speed and means for engaging the said reduced speed gearing, the said reduced speed gearing being entirely disconnected when not in use, and being introduced and disengaged by a longitudinally sliding movement.

19—In a motor vehicle, the combination with the motor and driving wheels of a gearing connecting the two, the said gearing comprising longitudinally aligned driving and driven shafts and a clutch for connecting the two for driving the driven shaft at high speed, and reduced speed gearing and reverse gearing for positively driving the shaft at a reduced speed, or in the reverse direction, and means for engaging the said reduced gearing and reverse gearing, the said reduced speed gearing and reverse gearing being entirely disconnected when not in use, and being introduced and disengaged by a longitudinally sliding movement.

20—In a motor vehicle the combination with the motor and driving wheels, of a gearing connecting the two, the said gearing comprising a longitudinal shaft, a clutch connecting the shaft to the motor and by means of which it is driven, connections between the shaft and the driving wheels, and a change speed device for rotating a portion of the shaft at a less speed than the motor, the said change speed device comprising an auxiliary shaft and gears on the longitudinal shaft, and means for intermeshing the gears by a sliding movement.

21—In a motor vehicle, the combination with the motor and driving wheels of a gearing connecting the two, the said gearing comprising a longitudinal shaft, a clutch connecting the shaft to the motor, and by means of which it is driven, connections between the shaft and the driving wheels and a change speed device for rotating a portion of the shaft at a less speed than the motor, the said change speed device comprising an auxiliary shaft, and gears on the longitudinal shaft and means for intermeshing the gears by a sliding movement, the said means comprising a single manually operated lever.

22—In a motor vehicle the combination with the motor and driving wheels, of a gearing connecting the two, the said gearing comprising a longitudinal shaft, a clutch connecting the shaft to the motor, and by means of which it is driven, connections between the shaft and the driving wheels and a change speed device for rotating a portion of the shaft at a less speed than the motor, the said change speed device comprising an auxiliary shaft, mounted in rigid bearings, gears rigidly mounted on the auxiliary shaft and gears on the longitudinal shaft, and means for intermeshing the gears by a sliding movement.

23—In a motor vehicle the combination with a driving shaft made in two parts, of a clutch made in two parts and connecting the shaft parts, one of the clutch parts sliding upon its supporting shaft part, a gear connected to the sliding clutch part and sliding with it, an auxiliary shaft, gears thereon and means for sliding the moving clutch part and its companion gear to disengage the two shaft parts and engage the gear with a gear on the auxiliary shaft, to cause the two shaft parts to rotate at a different speed relation.

24—In a motor vehicle the combination with a driving shaft in two parts, of a clutch made in two parts and connecting the shaft parts, one of the clutch parts sliding upon its supporting shaft part, a gear connected to the sliding clutch part and sliding with it, a gear on the other shaft part and rotating with it, an auxiliary shaft gear thereon, the said shaft being mounted in rigid bearings and means for sliding the moving clutch part and its companion gear to disengage the two shaft parts and engage the gear with a gear on the auxiliary shaft, to cause the two shaft parts to rotate in a different relation.

25—In a motor vehicle, the combination with a driving shaft made in two parts, of a clutch made in two parts and connecting the two shaft parts, one of the clutch parts sliding upon its supporting shaft part, a gear connected to the sliding clutch part and sliding with it, a gear on the other shaft part and rotating with it, an auxiliary shaft, gears thereon, the gears being rigidly mounted on the shaft and means for sliding the moving clutch part and its companion gear to disengage the two shaft parts and engage the gear with a gear on the auxiliary shaft to cause the two shaft parts to rotate in a different speed relation.

26—In a motor vehicle the combination with a driving shaft made in two parts, of a gear case, a clutch made in two parts and connecting the two shaft parts, one of the clutch parts sliding upon its supporting shaft part, a gear connected to the sliding clutch part and sliding with it, a gear on the other shaft part and rotating with it, an auxiliary shaft, mounted in rigid bearings, carried by the gear case, gears movable in a fixed plane with respect to said shaft, on the auxiliary shaft and means for longitudinally sliding the moving clutch part and its companion gear to disengage the two shaft parts and engage the gear with a gear on the auxiliary shaft to cause the two shaft parts to rotate in a different speed relation.

27—In a motor vehicle, the combination with a driving shaft made in two parts, of a gear case, bearings on the gear case for the shaft parts, a clutch made in two parts and connecting the two shaft parts, one of the clutch parts sliding upon its supporting shaft part, a gear connected to the sliding clutch part and sliding with it, a gear on the other shaft part and rotating with it, an auxiliary shaft, mounted in rigid bearings, carried by the gear case, gears on the auxiliary shaft, the said gears being rigidly mounted on the shaft and means for sliding the moving clutch part and its companion gear to disengage the two shaft parts and engage the gear with a gear on the auxiliary shaft to cause the two shaft parts to rotate in a different speed relation.

28—In a motor vehicle, the combination with a shaft made in two parts of a gear case, bearings on the gear case for the shaft parts, a clutch made in two parts and connecting the two shaft parts, one of the clutch parts sliding upon its supporting shaft part, a gear connected to the sliding clutch part and sliding with it, a gear upon the other shaft part and rotating with it, an auxiliary shaft, mounted in rigid bearings carried by the gear case, gears on the auxiliary shaft, and means carried within the gear case for sliding the moving clutch part and its companion gear to disengage the two shaft parts and engage the gear with a gear on the auxiliary shaft to cause the two shaft parts to rotate in a different speed relation.

29—In a motor vehicle the combination with a driving shaft made in two parts, of a gear case, bearings on the gear case for the shaft parts, a clutch made in two parts and connecting the two shaft parts, one of the clutch parts sliding upon its supporting shaft part, a gear connected to the sliding clutch part and sliding with it, a gear on the other shaft part and rotating with it, an auxiliary shaft mounted in rigid bearings carried by the gear case, gears on the auxiliary shaft, the said gears being rigidly mounted on the shaft, and means carried within the gear case for sliding the moving clutch part and its companion to disengage the two shaft parts and engage the gear with a gear on the auxiliary shaft to cause the two shaft parts to rotate in a different speed relation.

Two Sections Rotate Separately

30—A motor vehicle having driving wheels, a motor, a shaft in line with the motor shaft, a clutch connecting the two to cause the shaft to rotate at the same speed as the motor, the shaft being longitudinally arranged between the driving wheels and divided into two sections, a device for connecting and disconnecting the two sections for causing them to rotate as an entirety or to permit independent rotation, means for rotating the rear section of the shaft at a lesser speed than the motor or in a reverse direction, said means including sliding gears, longitudinally movable in a fixed plane with respect to said shaft and mechanism for so moving said gears, and connections between the rear section of said shaft and the driving wheels, substantially as set forth.

31—In a motor vehicle, the combination with a shaft formed of two parts, a connecting clutch and a gear on each shaft part, of a second shaft and gears thereon, and a single lever for shifting the gears on the first shaft and actuating the clutch, substantially as set forth.

32—Transmission for a motor vehicle, having a shaft formed of two parts, one telescoping within the other, connecting clutch, a gear carried by one clutch member, a second gear connected to the first gear but freely rotatable with respect thereto, a second shaft, and gears thereon and a single lever for shifting said first gears, and actuating the clutch substantially as described.

33—In a motor vehicle, the combination with a shaft formed of two parts, of a clutch connecting the two parts, a sleeve surrounding the abutting ends of the two parts, a gear formed integral with the clutch, and engaging with one part, a second gear formed integral with the sleeve and engaging with the other part, an auxiliary shaft, gears thereon disengaged at the high speed, intermediate gears interposed between the gears on the second shaft, and means for moving the sleeve, clutch and gears to disengage the two shaft parts and intermesh the gears, whereby the two parts of the shaft may be caused to rotate in different speed relations, substantially as described.

34—Transmission gearing for a motor vehicle having a shaft formed of two parts, one telescoping within the other, a connecting clutch, a gear integrally formed upon one clutch member, a second gear, a sleeve thereon, connecting with, but freely rotatable with respect to the first gear, a second shaft with gears thereon and a single-shifting lever for sliding said first gears and disengaging the clutch, substantially as described.

35—In a motor vehicle, a gear case therefor, having a cover and supporting brackets, with a set of common securing bolts.

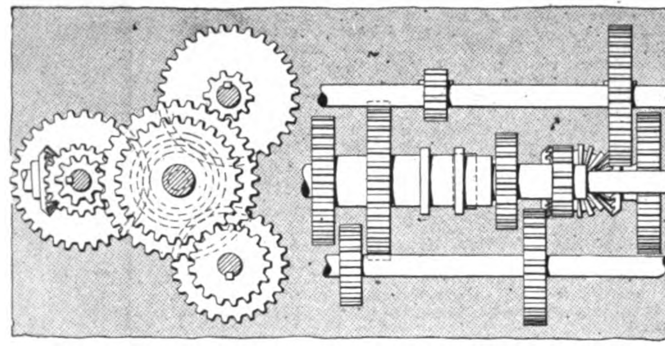
36—In a motor vehicle, a combination of a shaft therefor, formed in two parts, a fixed clutch member on one part, a movable clutch member on the other, gears connected to said movable member, a plurality of auxiliary shafts, gears thereon, and means for sliding said movable clutch member and connected gears along the shaft to disengage the clutch and intermesh the gears seriatim, substantially as and for the purposes set forth.

37—In a motor vehicle, the combination with the shaft, formed in two parts, of a clutch for connecting parts together to cause the shaft to rotate as an entirety, slidable gears on the shaft's parts, connecting to and working with one clutch member, auxiliary shafts with gears thereon, and means, which being moved, will first disengage the clutch and move the gears to a position to engage with the gears on one auxiliary shaft to cause the shaft's parts to partake of the different speed relations, and the continuation of the movement will cause the gears to engage with the gears on the other auxiliary shaft and cause the shaft's parts to rotate in opposite directions, substantially as and for the purposes set forth.

38—In a motor vehicle, the combination with an operating motor, of connections between the motor and the driving wheels, comprising a two-piece shaft connected thereto, connections to said shaft and driving wheels, a clutch connecting the two parts of the shaft, a gear carried by one part of the shaft, a second gear carried by the other part, connections between the gears and the clutch for moving altogether, an auxiliary shaft, two gears secured thereto, out of mesh with the other two gears at the high speed, a second auxiliary shaft, two gears secured thereto, normally out of mesh with the first two gears, intermediate gearing interposed between the two gears on the second auxiliary shaft, and means for disengaging the clutch and intermeshing the different gears, whereby the two parts of the shaft may be caused to rotate in different speed relations.

39—In a motor vehicle, the combination with the driving shaft made in two parts, of the clutch connecting the two parts, a sleeve surrounding the abutting ends of the two parts, a gear formed integral with the clutch, a second gear formed integral with the sleeve and engaging with the other part, and an auxiliary shaft, gears thereon, disengaged at a high speed, and means for moving the sleeve, clutch and gears to disengage the two shaft parts and intermesh the gears, whereby the two parts of the shaft may be caused to rotate in different speed relations.

40—In a motor vehicle, the combination with the driving shaft made in two parts of a clutch connecting the two parts, a sleeve surrounding the abutting ends of the two parts, a gear formed integral with the clutch,



Figs. 6 and 7—End and top views of patented device

a second gear formed integral with the sleeve and engaging with the other part, an auxiliary shaft, gears thereon, disengaged at the high speed, a second auxiliary shaft, gears thereon, disengaged at the high speed and means for moving the sleeve, gears and clutch to disengage the two shaft parts and intermesh the gears, whereby the two parts of the shaft may be caused to rotate in different speed relations.

41—In a motor vehicle, the combination with the driving shaft made in two parts, of a clutch connecting the two parts, a sleeve surrounding the abutting ends of the two parts, a gear formed integral with the clutch and engaging with one part, a second gear formed integral with the sleeve and engaging with the other part, and an auxiliary shaft, gears thereon, disengaged at the high speed, intermediate gearing interposed between the gears, means for moving the sleeve, clutch and gears to disengage the two shaft parts and intermesh the gears, whereby the two parts of the shaft may be caused to rotate in different speed relations.

42—In a motor vehicle, the combination with a motor and driving wheels, of connections between said motor and the driving wheels, including a two-piece shaft, a clutch connecting the two shaft pieces, gears upon the shaft pieces and auxiliary shaft with gears thereon, said gears being so arranged as to be out of mesh when the clutch is engaged, and an element longitudinally shiftable as an entirety for actuating said clutch and intermeshing said gears, substantially as and for the purposes set forth.

43—In a motor vehicle, the combination with the shaft formed in two parts, one telescoping within the other, of a connecting clutch, a gear integrally formed upon one clutch member, a second gear connected to the first gear but freely rotatable with respect thereto, a second shaft, and gears thereon and a single lever for shifting said first gears and actuating the clutch, substantially as described.

44—In a motor vehicle, the combination with the driving shaft formed in two parts, of a fixed clutch member on one part, a sliding clutch member on the other part, a gear rigidly connected to said slidable member, a gear rotatably connected to said slidable member, an auxiliary shaft, gears thereon, and means for moving said slidable clutch member and connected gears along the shaft to disengage the clutch and intermesh the gears, substantially as and for the purposes set forth.

45—In a motor vehicle, the combination with an operating motor, of connections between the motor and the driving wheels, comprising a two-piece shaft connected thereto, the connections between said shaft and driving wheels, a clutch connecting the two parts of the shaft, a gear carried by one part of the shaft, a second gear carried by the other part, connections between the gears and clutch for moving all together, an auxiliary shaft, two gears secured together, out of mesh with the other two gears at the high speed, a second auxiliary shaft, two gears secured thereto out of mesh with the first two gears at the high speed, and means for disengaging the clutch and intermeshing the gears, whereby the two parts of the shaft may be caused to rotate in different speed relations.

46—In a motor vehicle, the combination of the driving wheels, the motor, the driving shaft between the motor and driving wheels, made of two longitudinally aligned sections, a clutch arranged to couple the sections so that the driving shaft may turn as an entirety and longitudinally sliding speed reducing gearing arranged to connect the shaft sections, and so coordinated with said clutch that the engagement of said gearing will effect the prior disengagement of said clutch and vice versa, substantially as described.

Details of Dyer's Transmission Claims

47—In combination in a change speed mechanism, a driving shaft, a driven shaft, gears mounted upon said driving shaft and driven shaft, intermediate gears on an axis in fixed relation with the axis of said driving and driven shafts, means for transmitting power from said driving shaft to said driven shaft through said intermediate gears, and means movable on the driven shaft for directly connecting the driving and driven shaft with all intermediate gears at rest.

48—In combination in a change speed mechanism, a driving and a driven shaft arranged in the same axial line and adapted to have independent movement, change gears carried upon the driving and driven shafts, means for varying the position of said gears, power transmitting means adapted to connect a gear on said driving shaft and on said driven shaft and a clutch mechanism for directly connecting said driving and driven shafts.

49—In combination in a change speed mechanism, a driving shaft, a gear borne upon said shaft, a counter shaft, a gear borne upon the counter shaft and meshing with the gear upon the driving shaft, a driven shaft operatively arranged with relation to the driving shaft and provided with a clutch mechanism adapted to clutch it directly to said shaft, and intermediate gears borne upon the driven shaft and counter shaft, whereby the speed of the former may be varied with relation to the speed of the latter.

50—In combination in a change speed mechanism, a driving shaft and driven shaft, a driving gear for the former, a plurality of intermediate gears including a reversing gear and means for driving said driven shaft through any one of said intermediate gears.

51—In combination in a change speed mechanism, a driving shaft, a driven shaft, a plurality of transmission gears mounted to slide thereon, a plurality of intermediate gears arranged to engage and drive respectively, but singly, the said transmission gears, and means to couple said driven shaft directly to said driving shaft.

52—In a motor vehicle, the motor, clutch, driving gear and driven shaft, all axially aligned, means to drive said driven shaft from said driving gear at the same and also at different speeds, a jack-shaft arranged at an angle with said driven shaft and driven therefrom, and vehicle driving wheels connected with and driven from said jack-shaft.

53—In combination in a change speed mechanism, a driving shaft, a driven shaft, a counter shaft in fixed relation to said driving and driven shafts, an operative gearing on said shafts, and inclosing casing, a bearing in said casing for one end of the driven shaft, the other bearing for said driven shaft being in the driving shaft.

54—In combination in a change speed mechanism, a driving shaft and a driven shaft, operatively arranged, an inclosing casing, a bearing in said casing for one end of one of said shafts, the other end of said shaft having a bearing in the other shaft, a counter shaft in fixed relation to said driving and driven shafts and a plurality of gears connecting said counter driving and driven shafts.

55—In combination in a change speed mechanism, a driving shaft and a driven shaft axially aligned, a counter shaft in fixed relation to said driving and driven shafts, a plurality of gears connecting and said counter, driving and driven shafts, an inclosing casing, a bearing in said casing for one end of the driven shaft, the other end having a bearing in the driving shaft.

56—In combination in a change mechanism, a driving shaft and a driven shaft, the driven shaft having a bearing in the driving shaft, and means movable on the driven shaft to engage the surrounding end of the driving shaft to rotate the two shafts at the same speed, a counter shaft in operative fixed relation to said driving and driven shafts and a plurality of gears connecting said counter, driving and driven shafts.

57—In a transmission mechanism, for motor vehicles, a casing, a driving shaft or shaft section projecting into said casing at one side, a bearing therefor, in the wall of said casing, a gear and clutch part fixedly secured on or integral with said shaft section, and entirely on one side of said bearing within said casing, a driven shaft in said casing having a movable complementary clutch part, a counter shaft in fixed relation to said driving and driven shaft, and a plurality of gears on said shaft whereby varying speeds are transmitted to a shaft projecting from said casing.

Leonard Huntress Dyer
(Photo by Mrs. Dyer)

High-lights in Inventor's Life

Leonard H. Dyer was born May 13, 1873, in Washington, D. C. He was educated in the schools of Washington and later at Columbian University and Georgetown University, specializing in mechanics and electric science. From early boyhood his trend toward inventions has been apparent. Among his inventions is numbered an electric steering gear for ships, which is now owned by the General Electric Company and several improvements upon apparatus related to the cotton industry.

Early in the career of Mr. Dyer he became interested in automobiles and he has always held the belief gained from his investigation that the internal combustion engine would be a favorite of destiny.

In 1897 he devoted the entire year to the building of automobiles and constructed three cars of full size that were successfully demonstrated, all using gasoline engines, thus indicating that he was among the pioneer builders of the industry.

In 1903 he entered the firm of Dyer, Dyer and Taylor and engaged in the practice of patent law. In 1908 the two patents mainly involved in the license rights granted to the Automobile Board of Trade were transferred to the Enterprize Automobile Company.

John R. Taylor has been president of that corporation until recently, when he resigned and Mr. Dyer was chosen president in his stead.

Mr. Dyer is married and resides at Greenwich, Conn.

In speaking of his patents and particularly referring to patents 885,986 and 921,963, Mr. Dyer said recently:

"When Mr. Redding said that a comprehensive research of the prior art developed nothing sound upon which a defense against the patents could be based, he confirmed my opinion. Any such search as he prosecuted is bound to turn up a mass of data, but in this instance none of it could be applied by the defense. This is demonstrated by the fact that Mr. Redding's clients have agreed to take out manufacturing licenses.

"There has been a widely circulated opinion that the Dyer patents were allowed to sleep in the Patent Office and after the industry had grown up around them were issued. This is not true. The exact fact in the case is that through interference proceeding with the Renault patent, application for which was pending coincidentally with my own, the dates and claims of my patent were revealed and the industry appropriated my idea and incorporated it into the modern automobile.

"Imagine, if possible, the elimination of my idea from modern construction and then the importance of my device will be obvious.

"As to the prior art, there is none. Of course there can be found a record of a vast amount of ineffectual endeavor, but there is a difference between ineffectual endeavor and desire to attain a certain result and the actual accomplishment of such a result.

"The American situation is embodied in the Dyer patents, 1900, Renault patent 1901, Law, Leonard and Riker 1903. These records are all available to searchers and if any of them antedated my patents, Mr. Redding surely would have discovered them. In the foreign art there is nothing effective, despite the large quantity of abortive and ineffectual material revealed by a careful search.

"I demanded interference proceeding in the Patent Office when the Renault patent was issued and the whole record of the proceedings is available. The fact that despite the proceedings, my patent was issued as antedating that of Renault ought to be conclusive. The French Renault patent was issued in 1904.

"As a firm believer in the permanent usefulness of the automobile, I will say that I am on the constructive side. I do not wish to tear down; I wish to aid in building up."

Prosecution of individual owners of automobiles by the Enterprise Automobile Company for alleged infringement of the Dyer transmission patents has not yet been checked, despite the favorable outcome of the negotiations with the Automobile Board of Trade. The following suits have been entered this week in the United States District Court on behalf of the Enterprise Automobile Company: George Litwin, Frontenac; Sidney Ascher, Decauville; Oscar L. Lines, Mais; Edwin F. Brush, C. G. V.; John Beshar, Charron, and Desire E. Manduse, Clement-Bayard.

Supply Company in Receiver's Hands

COLUMBUS, OHIO, Aug. 12—The Brandt & Johnston Auto Supply Company, which has been operating a plant in South Columbus, O., for a number of years, was thrown in the hands of Fred W. Herbst as receiver upon the application of the City National Bank of Columbus, who claimed to be unable to collect a judgment of $5,000 against the corporation. The officials of the company did not oppose the action, although they contended the concern is solvent. It is alleged that bill receivable more than offset the debts of the concern and that $200,000 worth of business is on the books. The plant will be continued in operation under Charles Barndt and W. R. Johnson as managers. The petition was one of the results of the death of Dr. L. M. Early, a heavy stockholder in the company.

Prest-O-Lite Sues Searchlight

INDIANAPOLIS, IND., Aug. 12—Another suit defending its patents has been brought in the Federal Court in this city by the Prest-O-Lite Company. The new case is directed against the Searchlight Gas Company of Ohio and is very similar to cases which have been brought against other concerns manufacturing and selling devices which the Prest-O-Lite company claimed were infringements on its patents.

An injunction against the infringement of the Prest-O-Lite patents and an accounting are demanded in the suit. It is alleged that the Searchlight company has refilled Prest-O-Lite tanks. These tanks are trade-marked and it is alleged that refilling the tanks is an infringement of this trade-mark.

The Searchlight Gas Company has an office in this city.

Report on Oldfield Bill

Calls Attention to Numerous Evils Which the Measure Will Scotch—Limits Rights to 19 Years

WASHINGTON, D. C., Aug. 10—Of vital interest to the motor car and accessory industries is the report made to Congress this week on the Oldfield patent bill. Broad changes in the patent laws, recommendations for changes in the equipment and organization of the patent office are outlined in the report. The bill has been fought bitterly by manufacturers all over the country.

It seeks to make great changes in existing conditions, one feature being a section prohibiting a manufacturer from bringing suit for infringement of patents against a dealer who sells the manufacturer goods at a less price than that fixed by the manufacturer as a retail price.

"As to the wealthy corporations," says the report, "it has become obvious that the skilful handling of patent cases gives them an untold advantage over their smaller competitors. For them a well organized patent department is a reliable machine, where money is the lubricant. This machine, in its slow but grinding way, can reduce to pulp any of the smaller competitors. For large corporations, the maintenance of such a machine, with a staff of lawyers and experts, is merely a small side expense. By its aid they can bluff their weaker competitors into quick submission. If this is not successful, they can drag out a patent suit indefinitely until the weak opponent, unable to bear the ever-increasing expenses, collapses and withdraws."

The evils spoken of in the report cover a broad field of activity. The habit of manufacturers fixing a retail price for their goods is one, the custom of manufacturers of patented articles stipulating in what manner they shall be used is another; and the third evil is a phase of the trust problem, whereby owners of patents suppress them with a view to killing competition.

The bill has a clause limiting a patent right to 19 years exclusive of the time actually consumed in the patent office in considering it, or by the courts in deciding some phase of it. "This provision," says the report, "is aimed at the procrastination that has become proverbial on the part of applicants for patents."

The bill seeks to upset the present practice of considering as an infringement of a patent any sale of any patented article below price fixed by the manufacturer. For instance, many well known articles of everyday use, particularly in the motor car accessory trade, have the same retail price the world over. This is a matter controlled by the manufacturer and any cut-rate sale is liable to a suit in the United States courts on the ground that it is an infringement. The bill would make it not a matter of suit on the patent, but simply a matter of contract with manufacturer and dealer.

Rochester Orphans Enjoy Outing

ROCHESTER, N. Y., Aug. 10—Rochester's annual orphans' day held last Tuesday was a great success, 762 orphans being driven in 284 automobiles to Ontario Beach Park where the parentless children had access to every amusement on the grounds.

Headed by the automobile owned by President C. J. Brown, of the Rochester Automobile Club, in which were seated Mayor Edgerton, of Rochester; his secretary, Bernard J. Haggerty, and Commissioner of Public Works Herbert W. Pierce, the procession of automobiles started at 1 o'clock and paraded through the prominent streets of this city to Ontario Beach. After the many children were unloaded from the machines at the amusement resort, the automobiles were parked along the lake shore extending along Ontario Park beach and beside the grandstand. The procession returned with their occupants at 5 o'clock to the various institutions where the orphans are confined.

Trade News of the Week

Detroit Factories Planning to Ship 330,-000 Automobiles During the Coming Trade Year

Philadelphian to Make Wire Wheels Under Rudge-Witworth Patent—Rubber Lower Than Last Year

DETROIT, MICH., Aug. 12—To formulate plans for furnishing all the railroad cars which will be necessary for the handling of the 1913 shipments of automobiles from this territory, a conference was held on August 7 at the Board of Commerce between that organization's traffic bureau and local automobile factory representatives.

Detroit motor car manufacturers will require 102,000 freight cars for the shipment of their 1913 output. On this basis the above figures mean that Detroit's contribution to the automobile world for the coming season will be about 330,000 automobiles.

The problem faced by the railroads, manufacturers and the traffic bureau is to determine the best manner in which to get the necessary freight cars into Detroit for transporting the motor cars to their destinations and for returning them for reloading.

The conference was attended by a number of railroad officials in addition to the motor car men. Harry Moule, chairman of the Detroit committee of the National Association of Automobile Manufacturers, presided, while the Board of Commerce traffic bureau was represented by A. T. Waterfall. Representatives of the following automobile concerns were present: Abbott, Anderson, Buick, Chalmers, Cadillac, Ford, General Motors, Hupp, Hudson, Krit, Lozier, Oakland, Packard, R-C-H, Reo, Regal and Willys-Overland.

Lloyd with International Motor

R. M. Lloyd, who has been vice-president of the General Vehicle Company for several years, resigned recently from that corporation to take a position as assistant to the president of the International Motor Company, manufacturers of the Saurer, Hewitt and Mack trucks.

Formal announcement of the change was not made until after it had taken place and Mr. Lloyd had been installed in his new work. No announcement has been made by President Coleman, of the International, or President Wagoner, of the General Vehicle Company, as to the significance of the move.

Van Sicklen Goes to Motor Field

N. H. Van Sicklen, Jr., who for the past year has been associated with the Class Journal Company as office manager, and for 8 years previously occupied a similar position with *Motor Age*, has bought an interest in the Wahlgreen Publishing Company, Denver, Col., publishers of *Motor Field*. Mr. Van Sicklen takes to his new venture the well wishes of the hosts of friends he has made during his long experience in the automobile publication field.

To Make English Wire Wheels Here

PHILADELPHIA, PA., Aug. 13—The Geo. W. Houk Company, of this city, which has the American rights for manufacturing the Rudge-Whitworth detachable wire wheels, an English invention, has completed arrangements with the Standard Roller Bearing Company, of this city, for the manufacture of these wheels for the American trade. The Standard company at its plant in this city has sufficient manufacturing space available and is already engaged in equipping it with the necessary machinery for the manufacture of the wheels. It is expected that the manufactur ing will begin in 30 days. Reports are to the effect that severa of the large car manufacturers have already blue prints com pleted and are showing specifications and requirements for hu constructions for their particular cars.

Edwards to Locate on Long Island

Official announcement has been made that the Edwards Moto Car Company will be located in the plant formerly used by th United States Metal Products Company at Long Island Cit for at least 1 year.

With regard to the establishment of a big assembling plai for trucks at Louisville, an option has been secured for such a undertaking, but whether it will be exercised depends largel upon the success that attends the financial negotiations now i progress with local Louisville capitalists.

Rubber Lower than Last Year

LONDON, Aug. 13—The volume of plantation rubber offerin at the fortnightly auctions so far this year have been nearly 1(000 tons against about 5,500 tons during the corresponding peri of 1911. The auction that began today will dispose of about 7 tons, although the exact amount cannot be known until the sa is concluded. Two large consignments are due to arrive befo the sale is finished. Prices secured have averaged lower th last year, the present level being almost 8d. lower per poun The mystifying quietude of the market for Para continues a there is an undertone of strength in the trading that would n seem to be warranted by the volume of general buying. Tho

Automobile Securities Quotations

There was a more active market for automobile securities du ing the past week. The movements were irregular, but in t main they were upward. The most notable advance in quo tions was that of Ajax-Grieb common, which was moved up 150 bid with sellers at 200. The trading was exceedingly light holders stiffened measurably when the bids went up. Unit States Motor Company had a lively action in both issues. I organization rumors which included revival of the talk that merger with Studebaker had been concluded led to sharp buyi that drove the preferred above 20. This was officially den and the real reason for the rise is the probability of a favora reorganization based upon the company's own resources. Go rich was easier in tone. A comparison with last year:

who are marketwise have scented another plan of valorization and as partial confirmation of their suspicions it has been rumored that 2,400 tons of Para have been quietly purchased and retired from the market. The market stands at $1.17 per pound for up-river fine Para with other grades of rubber on a corresponding basis.

Steel Bars Sold at Premium

The market for structural steel and soft steel bars has been enlivened recently by the placing of orders for 10,000 tons of the latter commodity by manufacturers of automobiles, mostly located at Detroit. Tht order in itself is not of remarkable size for this period of the year, but it was placed at premiums running from $1 to $5 a ton and was conditioned upon definite delivery dates.

Most of the steel involved in the automobile orders will be specially treated and much of it will be alloyed before it finds its way into the product of the factories.

Jewel Merged in Ohio Company

Columbus, O., Aug. 12—The Secretary of State of Ohio has authorized the amalgamation of the Jewel Carriage Company and the Ohio Motor Car Company, both of Cincinnati. Heretofore the Ohio car was manufactured and sold through the Jewel Carriage Company, but by the change the Jewel Carriage Company will forever lose its identity and the business will be carried on by the Ohio Motor Car Company, the carriage end of the business having been sold to the American Carriage Company, of Cincinnati, several months ago.

Market Changes for the Week

Tin was the most prominent feature of the metal market this week, in that renewed activity in this material raised the price 45 cents per 100 pounds. Fractional gains were also scored by both electrolytic and Lake Superior copper, which were accompanied by a somewhat firmer tone of dealing than was witnessed in the preceding weeks. The steady, fractional rise in antimony which evidenced itself during the past 3 months was continued when on Saturday the price rose to 7 5-8 cents a pound. Steel quotations remained unchanged, and the condition in such products as channel steel, where producers found no bids on their wares, continues from last week. Lead remained unchanged.

Oil and lubricants remained at their old prices, with the exception of cottonseed oil, the latter declining owing to speculative influences. Gasoline also remained unchanged. Fine upriver Para rubber rose 1 cent a pound during the week, closing firm at $1.17. The variations for the week follow:

Material	Wed.	Thurs.	Fri.	Sat.	Mon.	Tues.	Week's Change

Atlas Plant Not Yet Sold

Prospective Purchasers Cannot Agree on Bid—Detroit Capitalists Abandon Idea of Taking Over Works

Havers Company Acquires Former E-M-F Plant—Market Changes for the Week

INDIANAPOLIS, IND., Aug. 12—Although today was fixed for the sale of the Atlas Engine Works plant and property, Fred C. Gardner, receiver for the company, had no report to make to the court. Judge Clarence Weir is out of the city, but it is understood that upon his return the time for making the sale will be extended.

M. L. Thomsen, of Cleveland, who some time ago said a company of Eastern capitalists would submit a bid, sent a telegram saying the men with whom he was associated had been unable to agree on the matter of making a bid. Detroit capitalists, who were said to have been headed by Walter E. Flanders, and who were expected to bid, have withdrawn as prospective bidders. It is reported the men who expected to be interested in this deal have also disagreed.

It is reported there are other prospective bidders in sight, but their identity is not being made public at this time. The proposition is a large one to handle, including assuming bonds for $1,050,000 secured by a mortgage; another bond issue of $105,000 and receivership expenses and mercantile accounts aggregating about $80,000.

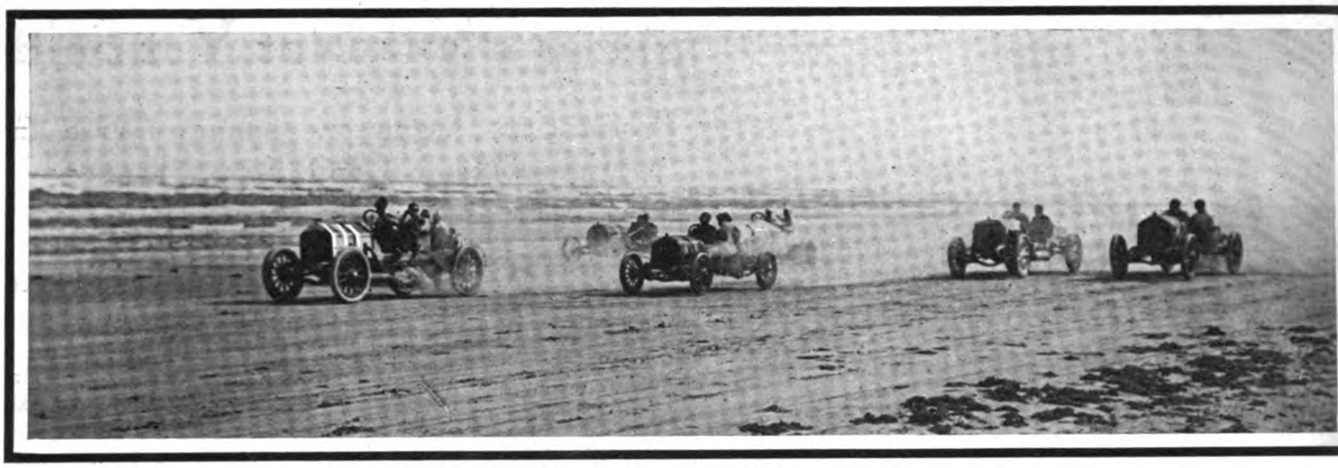
[Percy Martin, head of the British Daimler and Birmingham Small Arms companies of England, is in the United States on a visit that is scheduled to cover 6 weeks or more. Mr. Martin spent several days in New York, inspecting the Maxwell plant and conferring with various automobile interests and then went West, partly on a personal mission.

He is a native American and his present visit to this country is the first he has made in many years. His presence here has caused much speculation among the trade as to its reasons, as he is the leading exponent in England of the Knight motor and appears upon the scene at the time the affairs of the Atlas Engine Works of Indianapolis are in a much tangled condition. He has been in consultation with W. E. Strong, chairman of the Board of Directors of the United States Motor Company and accompanied Mr. Strong on a visit to Detroit last week for the purpose of inspecting the automobile field there.]

Havers Purchases E-M-F Plant

Port Huron, Mich., Aug. 12—The Havers Motor Car Company has purchased the E-M-F plant in the north end from the Studebakers and will manufacture from 1,200 to 1,500 cars in 1913. The E-M-F will begin at once the removal to Detroit and the Havers people expect to be able to occupy the local plant by September 1. The purchase price is not made public and the machinery of the E-M-F, with the exception of some of the shafting, was not included in the deal. The Havers now employs between sixty and seventy men. With the new facilities the number of employees will be greatly increased. Last year the company was able to turn out only 200 cars. That the plans for 1913 call for at least six times that number shows what the move will mean to this city.

The Havers company is a local concern with the following officers: President, A. D. Bennett; vice-president, H. L. Stevens; secretary-treasurer, A. J. Murphy; directors, David McMorran, S. L. Boyce, Edmund Harrington and Phil Higer. The company was one of the pioneers in the manufacture of six-cylinder cars and will continue the manufacture of this type.



Cars well bunched in the 75-mile race on the first day of the Galveston Beach meet

Disbrow Galveston Star

Captures 50-, 75- and 200-Mile Events With Simplex and Mercedes—Mason Second in Big Race

Mason, Case and National Feature in the Shorter Events, Each Winning Two

GALVESTON, TEX., Aug. 10—Signal success and big crowds marked the fourth annual automobile meet which came to a close here today. It was conducted, like its predecessors, under the auspices of the Galveston Racing Association and as one of the attractions of the Galveston Cotton Carnival.

The Galveston beach course is on the gulf side of the island. It is a straight and ideal stretch of 2 1-2 miles, and according to the statements of experienced drivers it has no superior in the country. The turns are all that could be desired. The fact that the hard sand beach is subjected to tidal inundation keeps it packed and smooth. The course is so laid out that the cars pass the grandstand twice in making each lap. The grandstand itself is a new structure with a seating capacity of 10,000 people. It was comfortably filled on each of the 3 days and besides this crowd tens of thousands of spectators viewed the racing from the open space along the course.

The entrants to the different events and classes numbered seventy-three, but a number of these failed to start.

The program for the 3 days was made up of ten events. F. E. Edwards, chairman of the technical committee of the A. A. A., besides performing the work of inspecting the mechanism of the different cars and putting his official stamp of approval upon the entries and classes, also had charge of the electrical timing machine. The referee was Mayor Lewis Fisher, of Galveston.

First Day

The program of the first day was made up of five events. Interest was centered in the last one on the list, a 75-mile race open to Class E (non-stock) cars of 600 cubic inches displacement and under. Louis A. Disbrow, driving his Simplex "Zip," easily took first money in this event. He started at a clip that quickly placed him in the lead and during the entire 75 miles he retained first position, but was closely pressed at different times by Clark, driving the Mercedes, the latter coming in a close second and never once losing its position next to the winning car. Disbrow also took second money in the second race, driving the Case White Streak. These two successes made him the hero of the day in the eyes of the spectators who applauded him every time he appeared on the course.

In the 75-mile race eleven cars were entered, but only five of the number completed the fifteen laps. As stated above, Disbrow, driving his Simplex Zip, won this event. His time was 1:09:16.72. The time of the Mercedes, Clark, which finished second, was 1:09:42.66. The Mason special, driven by Endicott, was third, in 1:12:16. The Case White Streak and the Mercer finished fourth and fifth, respectively. Summary of first day:

Car	Bore	Stroke	Driver	Time
Class C, non-stock, division 3-C, 15 miles				
Case Bullet	4 3-8	5	Nikrent	15:04.62
Case White Streak...	4 3-8	5	Disbrow	15:05.00
Mercer	4 3-8	5	Ferguson	15:09.70
Class C, non-stock, division 2-C				
Mason Special	3 13-16	5	Endicott	15:27.75
Flanders Special	4	4 1-2	Tower	15:57.55
Flanders Special	4	4 1-2	Evans	.16:09.89
Class C, non-stock, division 4-C, 20 miles				
National	5	5 11-16	Plummer	20:05.00
Stutz	4 1-4	6 1-2	Stolz	22:01.36
National	5	5 11-16	Melaum	(Flagged off)
Class C, non-stock, division 1-C, 10 miles				
Studebaker 20	3 5-8	3 3-4	Evans	11:07.09
Studebaker 20	3 5-8	3 3-4	Tower	11:11.91
Studebaker 20	3 5-8	3 3-4	Finch	(Distanced)
Class E, non-stock, 75 miles				
Simplex	5	5 3-4	Disbrow	1:09:16.72
Mercedes	5	7 1-4	Clark	1:09:42.66
Mason Special	3 13-16	5	Endicott	1:12:16.9
Case White Streak...	4 3-8	5	Ulbrecht	1:58:49.7
Mercer	4 3-8	5	Ferguson	2:00:20.0
National	5	5 11-16	Plummer	
Lozier	5 3-8	6	Horan	
Flanders Special	4	4 1-2	Evans	
Flanders Special	4	4 1-2	Tower	
Case Bullet	4 3-8	5	Nikrent	
National	5	5 11-16	Melaun	

Second Day

GALVESTON, TEX., Aug. 10—There was a good program o events for the second day of the meet. The crowd was almos as large as on the opening day.

The Simplex "Zip" easily won first place in the Clas D, free-for-all, covering the distance of 50 miles, we ahead of its nearest competitor on every lap. This event wa the fourth on the second day's program. The time of Simple "Zip" was 46:18.89. The other feature of this race was the unusu ally large field of entries. Seventeen cars lined up for the star They filled the entire beach course from side to side. Fir money amounted to $350. The second prize of $100 went the Mercedes, entrant, W. H. Bertrand, driver, Clark. This c showed better speed in the second day's events than in those the opening day, due to the fact that its gauge had been rea justed. The third place in this event was won by the Ca Bullet, entrant and driver, Joe Nikrent. The prize for thi place was $50. The Case special, J. A. Sloan, entrant, and Endicott, driver, came in fourth in this race.

In the 75-mile race Mr. Wagner disqualified driver Stolz for cutting across the course with his car, Stutz, which was entered by A. C. Bering. The second day's summaries follow:

Class E, non-stock, special, 25 miles

Car	Bore	Stroke	Driver	Time
Mason Special	3 13/16	5	Endicott	23:25.76
Flanders Special	4	4½	Evans	24:12.51
Flanders Special	4	4½	Tower	

Class E, special, 25 miles

Car	Bore	Stroke	Driver	Time
National	5	5 11/16	Plummer	23:54.69
Case White Streak	4⅜	5	Disbrow	26:10.37

Third Day.

Galveston, Tex., Aug. 10—There was much interest manifested in the effort to break the mile record, which was 37.8 seconds, made last season. This event came last on the day's program and it was well after darkness had begun to settle down that Disbrow in his Jay-Eye-See covered the mile in 31 11-100 sec-

The 200-mile race was not without its thrilling incidents. The onds. In the 200-mile race the Simplex Zip, Disbrow, driver, quickly caught the lead and it maintained it with varying regu- the 100th mile. All during the race the closest competitor of the Simplex was the Mason special, H. Endicott entrant and driver. This car made 180 miles before visiting the pit for gasoline or other purpose.

Class D, free-for-all, 200 miles

Car	Bore	Stroke	Driver	Time
Simplex "Zip"	5	5 3-4	Disbrow	186-17-19
Mason Special	3 13-16	5	H. Endicott	188-23-31
Mercedes	5	7 1-4	Clark	195-47-12
Flanders Special	4	4 1-2	Evans	216-47-44
National	5	5 11-16	Plummer	(Flagged Off) 37 Laps
Case Special	4 1-8	5 1-2	B. Endicott	(Failed to Finish)
Studebaker 20	3 5-8	3 3-4	Christie	" "

Boillot Wins at Ventoux

Grand Prix Victor Not Only Annexes The Honors, But Breaks the Record as Well

Covers the 13-Mile Course in 17.46, Lowering the Previous Best By 55 Seconds

La Garenne Colombes, France, Aug. 12—(Special Cable to The Automobile)—The Mont Ventoux hill climb has added another triumph to those already accumulated by the winner of the French Grand Prix, Boillot, with a Peugeot car again proving the winning combination and incidentally breaking the record for the hill climb.

The times made by the competitors were as follows:

UNLIMITED CLASS

Car	Driver	Time m. s.
Peugeot	Boillot	17:46
Cottin-Desgouttes	Deydier	18:38
Benz	Demoraes	18:49
Bugatti	Bugatti	19:16
Excelsior	Christaens	19:34
Lion-Peugeot	Thomas	21:14
Fiat	Tongazzi	21:51
Hispano-Suiza	Grua	22:50

TOURING CLASS

Car	Driver	Time m. s.
Cottin-Desgouttes	Pox	24:35
Schneider	Juvanon	28:11
Cid, Valveless	Naas	34:15
Cid	Thivolle	34:31
Cid	Robert	38:27
Apollo	Tonndorf	42:35

Mont Ventoux stands out as the oldest, the most important and the most difficult hill climb in France. With a total length of a fraction over 13 miles, its maximum percentage is 13 over the last few hundred yards, and after the first few hundred yards it rarely drops below 8 per cent. The percentage at distances of 5 kilometers are as follows:

5 kilometers	5.7 per cent.
10 kilometers	9 per cent.
15 kilometers	8.2 per cent.
20 kilometers	8.1 per cent.
21.6 kilometers (finish)	13 per cent.

Since 1909 the record for the hill has been held by Bablot, who on the Grand Prix Brasier driven by Thery at Dieppe the previous year climbed the hill in 18 minutes 41 seconds. This year's climb was rendered more interesting than usual by the presence of Boillot with the Peugeot racer.

Cleveland, O., Aug. 12—The clipping of 4 seconds from the 1-mile dirt track record for Cleveland made 3 years ago by Barney Oldfield on the old Glenville track, was the sum total of achievement at the all star meet promoted by the Burman-Moross bunch of barnstormers Wednesday, August 7, as a feature of the Eagle's convention.

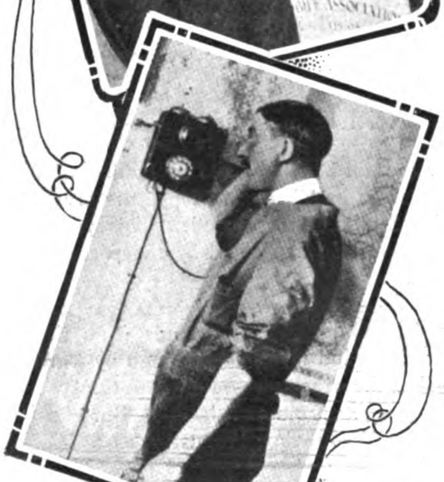
Sentry box equipped with telephone for use of members of British Automobile Club

Patrols for Motor Tourists

How the British Automobile Association Safeguards Traveling Over Highways—Roadside Phones Insure Prompt Assistance—Equipped for First-Aid Work



Patrolman

NOVEL and interesting to the American automobile tourist is the system of road patrols, road guides and wayside telephones in common use throughout Great Britain. The commencement of the present nation-wide institution was the movement initiated by the Automobile Association in 1905, when a few patrolmen were commissioned to travel over certain well-patronized sections of the highways to give aid of whatever nature to members of the association who desired it.

These patrols were prepared to give information with regard to roads and routes; to assist in making temporary repairs when required; to direct the inquiring member to the nearest garage, hotel or supply depot and to perform any other services that appeared to be necessary.

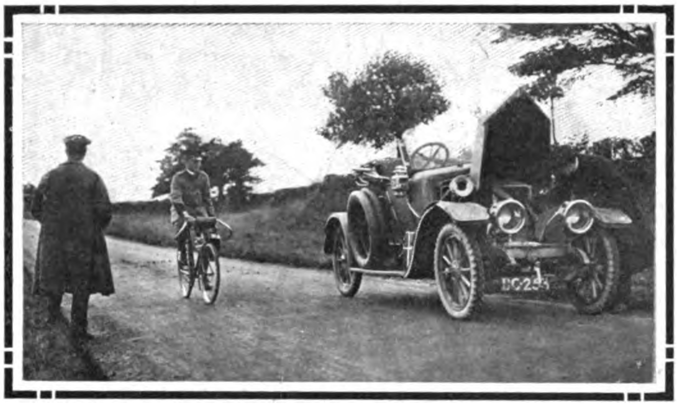
As the association grew, the system was extended until at present, the membership of the organization is nearly 49,000 and the patrol system covers 14,000 miles of highway.

By the last of August the roadside telephone system will be completed and at the service of the members. By means of this system of communication it will be possible for the automobile tourist who is affiliated with the association to get into close touch with garages, hotels and all points reached by the regular system. In case of mishap it will be possible for the tourist to communicate with home, friends or office from any of the patrol boxes of the association. These boxes are erected every 10 miles on the main roads radiating from all the chief cities.

Quick Relief When in Trouble

A telephone communicating with the nearest exchange is installed in each box. The telephones are at the service of members for all purposes, business or private use, breakdown or accident, entirely free of cost. Only in case of trunk-line calls is a tariff levied and it is never higher than the ordinary trunk-line fee. Each sentry box is available, both for local and trunk calls and for receiving, as well as transmitting messages. A patrol is on point duty at each box. Thus is the aim of the

Association badge



Patrol discovers automobilist in trouble and hastens to nearest sentry box to bring assistance

committee being realized, which is to give the motorist a practical organization, affording him practical help in a businesslike way; giving him free legal defense in any proceedings under the Motor Car Act; ensuring the comfort of members while on tour; supplying facilities for repairs during any hour, day or night, week days and Sundays; making easy the obtaining of spare parts; extending international touring facilities and engineering advice; maintaining patrols on all main roads; and extending first aid and prompt assistance in the event of accident or breakdown.

The Royal Automobile Club, realizing the value of some such system of road patrol, has installed a somewhat similar idea. The patrols are called guides and are instructed to give road information and to assist any member of the organization in any way possible in case of need.

Signals to Cars in Motion

Developments of the patrol idea are coming along with much speed and frequency. At present a system of whistle signals is being worked out so that the patrolman will be able to give certain information to the operators of automobiles after they have passed. Semi-deflated tires can be called to the attention of the driver by a certain signal; a loose license plate will be indicated by another; smoke in undue volume will be noticed with still another series of whistles.

Under present conditions the patrols have no way of communicating these facts to the driver unless the car is stopped, because if it continues on its way, the patrol realizes the conditions after the car has passed and it is then too late to stop it except in rare cases.

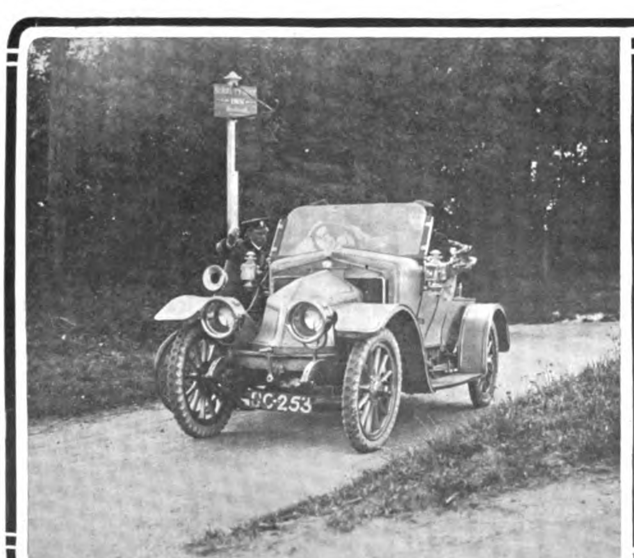
The character of the patrolmen has improved remarkably with the growth of the movement. Today, in order to hold such a post for the Automobile Association it is required that the man shall have a general knowledge of First Aid work and practice in case of mishaps; that he must have a good working knowledge of automobile repairs, maintenance and mechanism, and that he shall be energetic and observant as well as industrious and discriminating. He must be well up on road geography and capable of imparting information in an intelligent manner.

High-Price Gasoline in England

In discussing the recent boost in gasoline in England, where motorists now have to pay 32 cents a gallon for the fuel, R. M. Lockwood, head of the Regal Motor Car Company's foreign department, says: "The difficulties which the motorists of England face should make us thankful for two things. First, that the price of gasoline here is, in comparison, much lower, and second, that the industry in this country has advanced to the stage where we are producing cars that are actually economical in gasoline consumption.

"In America we do not always appreciate the fact that we pay a very low price for this necessity. In parts of Europe and certain localities in the Orient I have known the price to be as high as 60 cents a gallon. Quite naturally, the figure varies according to the facilities for receiving the gasoline. Here, where we have apparently an inexhaustible supply and good means of transportation, the price of the fuel is correspondingly low.

"Furthermore, our cars in most instances develop more power in proportion to the amount of gasoline consumed than do the cars of Europe. The average European car may use less gasoline, but it cannot mount the hills as easily as our cars can. Europeans are preferring the cars we export because they give better service for the gasoline consumed than the ones manufactured in their own countries."



Patrol directing automobile party to the nearest sentry box, where they may telephone for assistance

Ran out of fuel, patrol responds with gasoline
Patrol members must be adepts in first-aid service

Data Relating to One of the Centrifugal Pumps for Fire Engines Made in Germany—How the Interests of the Automobile Industry and the General Public are Identified with Either Centrifugal or Rotary Gear Pumps—Miscellany

CENTRIFUGAL **Fire Engine Pumps**—Fire engines of a construction which any automobile or motor truck manufacturer may take up without interfering with the system and routine of his other production, which are economical and compact and require little more care at the fire station than an ordinary automobile; which, further, are of light weight and may be taken readily and rapidly over any passable road from one town or village to another, in case of unusual conflagrations, and which may be served in emergencies by crews whose physical skill in fire-fighting is undeveloped, naturally recommend themselves to the attention of the public and its representatives as well as to that of specialists in a country like the United States, where the automobile movement is more popular than in any other country, and where, on the other hand, the art of fire prevention is much more backward, so that the total fire losses in a year per capita of population is about five times greater than the international average.

But although the leading feature of such a construction is the use of a centrifugal pump driven direct from the automobile motor, and the construction of centrifugal pumps in general owes its development principally to the ingenuity of American inventors and the enterprise of American firms, it is Germany which has led and is still leading in the simplification and cheapening of fire-fighting apparatus attainable by the use of the centrifugal pump on an automobile chassis. Only the rotary gear pump of German invention (see illustrated description in THE AUTOMOBILE of July 11) competes with the centrifugal type for securing the advantages referred to, a comparison disclosing advantages and disadvantages on both sides. In various extracts from articles in German journals THE AUTOMOBILE has recently given some of the most interesting facts relating to the German development, and in the following some supplementary notes are presented from an article by Werner Ahrens, an engineer with the Sulzer firm at its Winterthür plant, relating mostly to the Sulzer multiple centrifugal pump.

In the use of the centrifugal pump the speed of the pump shaft is the factor by which efficiency is secured. This speed, it might be said, takes the place of the close fit of piston and the alternating closing and opening of the valves in pumps with positive action. The maximum pressure which can possibly arise in the pipes and hose of a centrifugal pump is that determined by the maximum speed of the pump shaft. This is the same whether the hose nozzles are open or closed. To obtain efficiency without cumbersome special gearing it is necessary that the automobile motors used in fire engines of this type should be high-speed engines giving their best torque at more than 2,000 revolutions of the motor shaft, and this is the type of motors used. (The positive or almost positive rotary gear pump seems in this respect more adaptable to the slower-running automobile motors still prevailing in the United States, especially among motor truck makers.—ED.) A multiple centrifugal pump of the Sulzer manufacture with three centrifugating wheels fixed on the pump shaft is shown in Figs. 1, 2 and 3. Fig. 1 gives a sectional view of all but the evacuating pump (the exact construction of which does not seem to be made public anywhere, at present, perhaps because the liveliest competition among the various German pump makers bears upon improvement of this detail by which the advantages of the rotary gear pump are sought to be equalled). Fig. 2 shows the pump shaft and the centrifugating wheels on it, and Fig. 3 shows the dismounted parts of the complete pump in their sequence and to the right thereof the complete pump assembled. Each centrifugating wheel rotates within a stationary housing with circumferential discharge ports and separated from the housing of the next wheel by a baffle plate compelling the water thrown out of the first housing to enter the next wheel near its center.

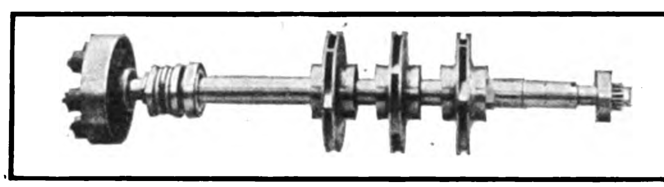

Fig. 2—The shaft and centrifugating wheels of the Sulzer pump

WATER ENTERS WHEELS ON BOTH SIDES

Provided the dimensions of the working parts and the speed of the shaft are properly suited to the quantity of water handled and the available power, the pressure created by the first wheel is doubled by the next wheel and tripled by the third. The capacity and the required power are proportionate to the square roots of the pressures. To obviate end-pressure on the ball bearings the water is made to enter into the centrifugating wheels on both sides. The evacuation pump is built in one with the centrifugal pumps, so that the whole pump plant may be mounted in the automobile chassis as a unit. It is of the reciprocating piston type and is built so as to operate not only as an air pump to evacuate the suction hose, but also as a water pump which may be left going in conjunction with the centrifugating pump. In other constructions the evacuation pump operates as air pump only, and a device is necessary for automatically closing it against the entrance of water. The illustrations show the pipe by which the evacuation pump is connected with the suction room of the centrifugal pump. When the stopcock on this pipe is closed the evacuation pump runs idle, as may be desirable when the whole pump is operating with the assistance of a considerable waterworks pressure.

As a flexible coupling is effected by merely shoving the pump shaft against the end of the transmission shaft, the mounting of a centrifugal pump consists merely in bolting it to the automobile chassis, and small misalignments are unimportant as the method of coupling admits of them. There is therefore an advantageous independence between the work of the automobile manufacturer and that of the pump maker.

By allowing the evacuation pump to be operated concurrently with the centrifugal pump, a special gear shift for the small pump is dispensed with and the service is simplified. But the principal advantage of this arrangement lies in the complete reliability of the pumping action which is gained as the evacuation pump disposes of all the air which may be, and nearly always is, present in the suction hose. For example, when the hose is carried over walls or other obstructions, air pockets are nearly always formed. And when the suction hose is disconnected in order to be attached to a new water source, air pockets are formed unless the valves and the hose itself are perfectly watertight. With the evacuation pump permanently attached—and working with either air or water—only 30 to 60 seconds are required for the evacuation of the air from the suction conduit when the engine arrives at a fire.

PUMP PERFORMANCE CAN BE REGULATED

All organs of the pump are made of bronze excepting the shaft and the ball bearings, and the weight of a complete pumping plant with evacuation attachment and dimensioned for a pressure of 100 meters and a capacity of 1,000 liters per minute by a power output of 32 horsepower, reaches only 330 kilograms, while one throwing 2,000 liters per minute with 80 meters pressure by means of 50 horsepower weighs 450 kilograms.

A comparison of working pressures and the amount of water ejected with the power efficiency attained at test performances shows that even without varying the number of revolutions of the pump shaft a considerable regulation of the pump performance can be effected. When, for example, the discharge is regulated from 15 liters per second to 30 liters per second at 1,600 revolutions per minute of the pump shaft and a power output of 70 horsepower, the manometer pressure is at the same time reduced from 115 meters to 85 meters.

When the number of revolutions is changed, similar variations may be obtained with each of the shaft speeds. A small change in the speed makes a considerable variation in the work results as the pressures vary with the squares of the number of revolutions, and this makes it possible to suit widely varying requirements with a small variety of pump models. But in order to select the most suitable model it is of advantage to take into consideration the waterwork pressure which is locally available.

Diagrams published by Mr. Ahrend show that the water throw realized at an angle of the nozzle of 50 degrees reached from 16 to 20 meters in height and from 31 to 41 meters in distance by means of pressures of 6, 8, 10 and 12 atmospheres, 10 atmospheres corresponding to about 100 meters manometer pressure, and that at a nozzle angle of 32 degrees the distances were raised from 44 to 56 meters.—From *Zeitschrift des Mitteleuropäische Motorwagen Vereins, medio* July.

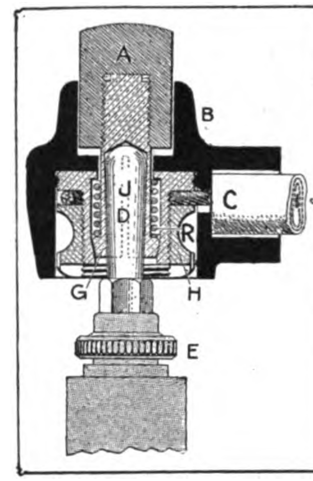

Fig. 4—Sectional view of Serfix device

To Secure Wires—Serfix is a neat little device whose mission is to hold ignition wires to spark-plugs without chance of accidental loosening and with some measure of protection against short-circuiting by rain. The connection is not inconveniently rigid, however, as the device may rotate a little around the terminal. The latter is shaped as a baseball bat and is inserted in the lower split and hollow part of a bolt G, whose upper part is screwed into the knob A made of insulating material. The lower end of this bolt G is conical and an interior conical surface on the surrounding metallic piece, which is not designated by any reference letter in the illustration, Fig. 4, is drawn against the conical part of G by means of the interposed spring R, thereby pressing G against the conical surface of the terminal D. The dotted lines marked J indicate the split. The wire is passed around the shank of the exterior piece and is held against its upper flange by the nut H. All the parts are inclosed in the cap B made of insulating material. In order to release the terminal from the wire it is necessary to press down upon cap B disengaging the two conical surfaces and while doing so to pull up at A.—From *Omnia,* July 27.

The Colors of Cars—Harmony in the colorings of of a car, and of any other large object, is restful, while discord brings about an indefinite sense of fatigue and displeasure. This well-known fact has given rise to theories by which the phenomenon is explained in a rational manner in accordance with the known laws of optics and light, and by the aid of which it may, in turn, become easier to avoid discordant colorings in the products of industry. This subject is treated by A. Rosenstiehl in the March bulletin of the Industrial Society of Mulhouse. Differently colored light rays do not come to a focus at the same angle of refraction when passing into the human eye or through any other refracting medium. This is established. It follows from this that if the eye shall see clearly a surface upon which several colorings are spread side by side it must accommodate itself at the same time to different distances, and this is fatiguing if the effort is made, while otherwise the impression is blurred and

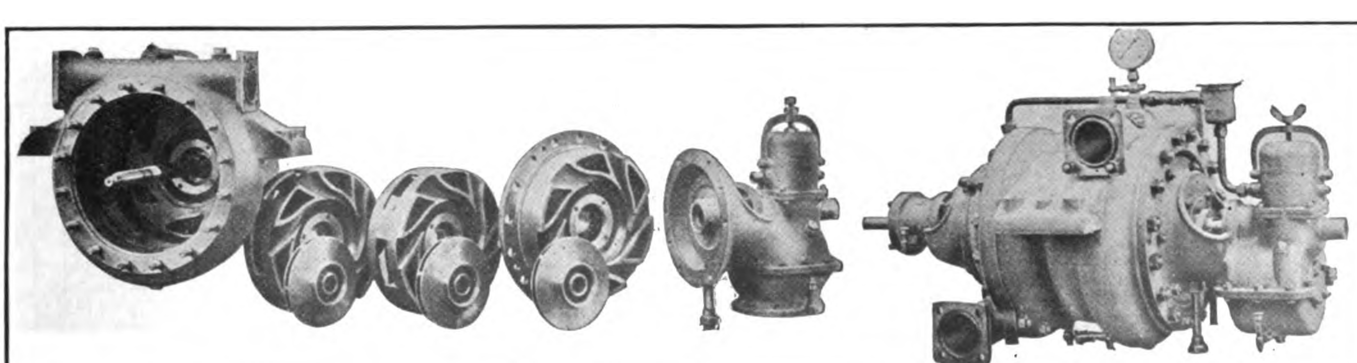

Fig. 3—Parts of the Sulzer centrifugal pump dismounted and shown in sequence. To the right, complete pump assembled

indistinct. It is also this difference in the refraction angles of the different colors which causes some colors to seem to recede and others to spring into relief. Red especially is a receding color. A red object seems farther away than a blue object placed in the same light and the same plane. In devising a color scheme it is important to avoid the clashes referred to, and this may be done by separating two sharply complementary colors by a neutral one whose angle of refraction lies between those of the two other ones and, especially, by adding white to at least one of two sharp colors. The author counsels particularly the latter method, which, according to his theory—presumably verified by experience—should render it practicable to obtain strong and yet not tiresome color effects without relying upon the artistic sensibilities of designers and workmen.—From *La Génie Civil* of July 13.

Stereoscopic Microscope—All who have occasion for examining polished and etched specimens of steel through an ordinary microscope with a single optic have experienced some difficulty in distinguishing the raised from the sunken parts. The image lacks perspective, and the expedient of rocking the microscope so as to make the shadows move and thereby indicate the formation is a makeshift which it is not always easy to apply. Only a partial relief from this difficulty has been offered through the binocular stereoscopic microscopes which so far have been in the market. They are constructed with two objective lenses and can therefore not be brought close to the object, and consequently the magnification is comparatively small, in fact limited to 80 diameters. They also fatigue the eye by inducing an effort for seeing the two images as one, especially when the observer is near-sighted, far-sighted or has eyes of different foci. A new construction has now been devised by Dr. Quidor, and it is manufactured by Nachet. In it a single objective is used and magnifications up to 400 diameters can be obtained. The light rays passing from the object through the objective lens are divided into two symmetrical bundles by means of two pairs of prisms and the observer perceives the perspective through the fusion of the two images. As in all other stereoscopic instruments the distance between the two oculars must correspond closely to the distance between the observer's eyes, but this adjustment is easily effected by rotation of one of the pairs of prisms. All fatigue of the eyes is said to be avoided. The advantages of the new construction were laid before the *Académie des Sciences* at its session of July 1.—From *Le Génie Civil*, July 13.

Aluminum Coat on Iron—A coat of lasting qualities can be produced by dipping an iron article in molten aluminum if the iron article is first dipped in alcohol so much diluted as not to be ignitable. Franz Jordan, of Berlin, has German patent on the process and kindred processes for aluminum-plating sheet iron by dipping and fixing the coat by reheating and rolling.—From *Metallurgie*, July 22.

Harking Back a Decade

What the Motoring Publications of 10 Years Ago Had to Say on Live Matters of the Day

FROM *The Automobile and Motor Review*, August 16, 1902: With a few exceptions, the business vehicles, power-driven, are electrically propelled, so far as New York City is concerned.

A special motor wagon for the delivery of mail on a rural free delivery route has been constructed after designs of George E. De Groot, a letter carrier of Morristown, N. J. The body of the wagon is divided into two parts, the front for the driver and the rear for the postman. The driver can not get out after he is once inside unless released by the carrier. The car is equipped with a 20-horsepower gasoline motor.

The automobile industry in Berlin gave employment to 1,000 men during 1901 and is growing steadily. So far, the patrons of the industry who can afford to pay from 8,000 to 10,000 marks for a car prefer to purchase outside of Germany.

The official tabulation of the recent Paris-Vienna race has been completed, involving the consideration of 16,000 sets of figures. The final result is not materially changed. The summary shows that eighty out of the 137 starters finished the full course. Of the finishers seventy-one were of French manufacture.

A Panhard, driven by Jarrott, won the heavy-car class in the Circuit des Ardennes. A Gobron-Brillie, alcohol car, won the light-car class, driven by Rigolly.

Can't Turn Out Cars Fast Enough

It is more than a coincidence that the announcement of the development of the kerosene burner for steam vehicles to a practical point comes simultaneously with the report of a shortage of high-test gasoline in certain New England localities. Editorial.

The Peerless Manufacturing Company, of Cleveland, despite a full force and a shop full of fine machinery has been able to turn out only three cars a week. Manager Kitridge announces that a deal is pending to acquire a factory plant at Lorain, O., so that a force of 400 men may be employed for next season's manufacturing.

The first American models of the C. G. V. car were completed last week at the Rome Locomotive & Machine Works, Rome, N. Y. The car is fitted with an American-made aluminum body and has a four-cylinder motor rated at 15 horsepower.

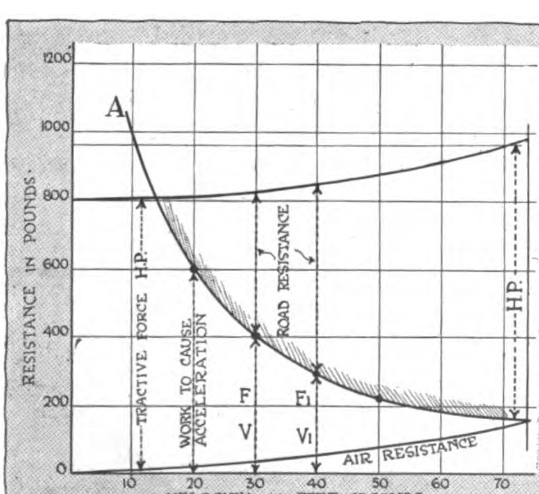

Fig. 1—The road resistance increases geometrically with velocity

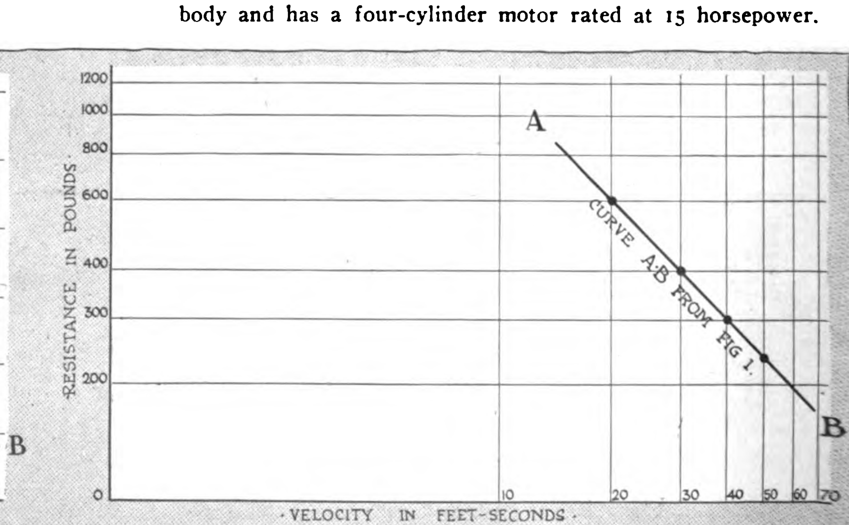

Fig. 2—Same condition shown by linear curve on logarithmic paper

Selecting Proper Gears

S. I. Fekete Shows a Simple Way of Determining Correct Ratio for Any Number of Speeds

IN the July 18 issue of THE AUTOMOBILE there was published a very remarkable article, by W. H. Cameron, on the subject of the four-speed gearset. In this he predicts its general adoption and its necessity. This article certainly came at the right time and on the right subject.

In this article I wish to introduce a very simple mechanical way of determining correct gear ratios for any number of speeds. At the same time I wish to call attention to Mr. Cameron's reasoning and explanations, but would not advise following his diagrams, illustrating the steps between the gears, for the reason below stated.

In the diagram where ordinate O X is apparently the time, while the gears are engaged and ordinate O Y stands for the velocity, miles per hour. If we were to make a diagram like that which he illustrates before laying out a set of gears, and in this diagram the steps between velocities were to be equal, then the result would be in some cases an error, because such a diagram gives us the arithmetical progress instead of that which we need, the geometrical progression.

Gears Should Progress Geometrically

According to my way of thinking the gears in a gear-set should progress in a geometrical progression because the resistance increases in the velocity interval in a hyperbolic curve. During acceleration the road resistance increases and is a function of the velocity. If we suppose there is one even condition of the roadbed, going at top speed, the road resistance consumes the power output of the motor. If we analyze the increase of the resistance, we find that it is in geometrical progression.

When a car starts, a certain amount of work is required to cause acceleration and the other part of this work is required to overcome the resistance of the car. The total tractive effort given by the motor is consumed by these two factors. When the resistance is so high as to consume all the tractive effort, then there is no more work left to cause acceleration and so the car begins to travel with a constant velocity. In equation:

Resistance = tractive force.

During acceleration the work is consumed by two factors, one which causes acceleration and the other is the resistance, that is

Force to cause acceleration + resistance = tractive effort.

If we imagine a constant horsepower output during acceleration, then

$$\text{Horsepower} = \text{constant} = (\text{force to cause acceleration}) \frac{V}{550}$$

or

$$\text{Horsepower} = \text{constant} = \left(\text{mass} \times \frac{olv}{olt}\right) \frac{V}{550}$$

And this is equation of a parabola.

Let F mean the force to cause acceleration in one interval (in Fig. 1) and V the velocity.

Farther F_1 — the force to cause acceleration in one other interval when the velocity is V_1.

Then

$$F \times V = \text{constant}$$
$$F_1 \times V_1 = \text{constant.}$$

This equation of a hyperbola referred to its asymptotes will represent the increase of resistance.

To prove that this curve in Fig. 1 is geometrical progression, it is necessary to plot it over on logarithmic paper. On this paper it should appear as a linear function.

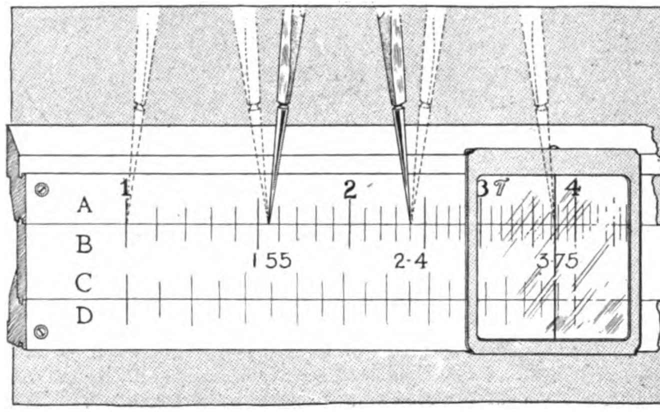

Fig. 3—Geometrical progression illustrated with a slide rule

In Fig. 2 ordinates O X are the values of the velocity and the scale used is a logarithmic scale of the slide rule.

Ordinate OY signifies the resistance in pounds on the same scale. On this diagram, if we take equal steps between gears taken, between any chosen points, then they will give us a geometrical progression.

If we take a divider and make steps on the scale, such reading will give us geometrical progression. To get any number of gear ratios between a chosen lowest ratio and to the direct drive, all that is necessary is to divide the slide rule into as many equal spaces as we want intermediate speeds. If we begin dividing at the point which is our lowest gear and take the readings where the dividing points come we will get the correct theoretical gear ratios. This division may be subject to change during process of designing, on account of inability to secure even center distances and pitch. See Fig. 3.

Lessons from London Rubber Show

Speaking to the colonial branch of the German Agronomic Society at a recent meeting, Professor Dr. Warburg, an expert on rubber questions, reported the impressions which he had received at the London rubber show held last year. It demonstrated the predominance of England and of Para rubber derived from the hevea rubber tree, he said. The English idea of cultivation and preparation was also ruling. Next to Great Britain, the country which made itself felt was Holland which showed rubber derived from ficus trees (same family as the fig tree) and guttapercha prepared from their leaves. The showing made by Germany, though assisted by the government, was inferior comparatively. Preparation methods were well exhibited, however, and the apparatus for rubber testing were brilliantly instructive. On the whole, the lessons of the show may be summarized as follows: (1) Para plantation rubber will rule the world markets in a few years under control from London; (2) where climate or high wages operate to disadvantage the exploitation of wild stands of rubber trees will stagnate or retrograde; (3) no immediate danger (?) of synthetic rubber crowding out the natural; (4) prices will in course of time drop considerably, as cost of production may be much reduced, but the danger (?) of overproduction of first-class rubber is still remote.

With regard to the probable fate of German rubber plantations the lecturer held that those in Kamerun and Togo as well as in New Guinea and the Samoan islands were not threatened. But in German East Africa the situation is different. Here 23,000,000 rubber trees, out of a total of 31,000,000 German-grown trees in all regions, are located and represent an investment of 20000,000 marks. These plantations are cultivated by people who know little of agriculture, and many blunders have been committed. The raw material obtained from them is not of the first-class and cannot meet the competition in the world markets. The trees are largely manchot and ficus.—From *Allgemeine Automobile-Zeitung*, June 28.

System in the Service Plant

Illustrated by the Methods Employed by the New York Distributors of the Garford

Fifteen Forms are Used and the System Requires the Entire Time of But One Man

Fig. 2—Repair tag used by R. & L. Co.

A GOOD business system is to a merchant what his multiplication tables are to the schoolboy. Both enable their operators to handle a large bulk of operations in a simple and efficient way; both present a means of checking at any given moment the results of preceding operations with an infallible reliability. It is as useless and as senseless for the present-day business man to attempt to conduct his affairs in a manner not in accord with modern methods, as it would be for a schoolboy to attempt the solution of arithmetical problems without the knowledge of the fundamental operations and the rule of three.

As the repair business is a necessary branch of the automobile trade, every improvement in the methods of carrying on the requisite operations will be welcomed by the progressive automobile business man. To him system means reduction of burden to a minimum and augmentation of profit to a maximum; moreover, the clever business man knows enough to keep the system as his servant and not to become the slave of the system. In selecting a recording system which will meet the requirements he will choose one which necessitates a relatively small amount of labor but which permits of recording every essential step in the repair of an automobile.

Division of the Work

The series of operations constituting the repairing of a car may be classified under three heads; the entrusting of the service department with the car, the work done on the car in the service department, and, finally, the testing and returning of the automobile to its owner.

In the first and third operations the owner is personally concerned, or at least is represented by his chauffeur, and his attention is naturally focused on the state the car is in before and after the repair and also on the condition of the automobile's equipment. The second operation, or rather set of operations, is of eminent importance to the owner of the service department. Therefore, the interest of the owner makes it necessary that the condition of the car be most closely examined before the machine enters the shop and after it leaves it, while it is of the utmost importance to the operator of the repair establishment to keep himself informed as to even the smallest expenditure of money, time and material in the repair of every automobile in his shop.

Recognizing this necessity, leading automobile companies have devised elaborate control systems serving the purpose outlined above. An up-to-date system, that of the R. & L. Company, New York City, distributors of Garford pleasure and commercial cars, is described below. The system covers practically every phase of modern service, so far as the repair of automobiles is concerned, and for this work thirteen separate cards and sheets are required. The purpose of these is as follows:

1. Two forms for outlining by the owner, the work to be done in the shop and to give an index of the equipment on the car, when it is turned over to the company.
2. A tag also giving a list of the repair jobs, and which is attached to the car.
3. Three forms, to record the labor required in the car repair.
4. Three forms to keep record of the material used.
5. One slip for enumerating outside or cash expenses made by men in connection with repair work.

LABOR COST

DATE					Amount	DATE					Amount	REMARKS

Fig. 4—Repair order. Fig. 5—Time and material record

6. One slip on which the working items which come under the guarantee are listed.

7. One form giving the results of tests made with the car by the company's inspector and by the chauffeur.

8. A daily service building report which is sent by the superintendent to the manager of the company; this sheet contains a detailed report of the work done in the establishment during the previous day and a statement of cars and materials received and delivered during the day. As this sheet also gives the number of new cars received from the factory and delivered to customers—the R. & L. Company also keeps its stock of cars at its service department—two more forms must be mentioned in this connection:

9. The delivery order giving the number of a car delivered to a purchaser, together with a statement of all the equipment furnished with it.

10. The receipt for delivery of such car to the purchaser.

In the following the various forms are described, each one being treated in detail and illustrated to show the advantageous arrangement of the various data on every blank here shown.

1. These forms are bound in books and are made out in duplicate, one copy of the document remaining permanently in the original binder. The other forms are kept in pads and are made out, in most cases, in duplicate, in one case even in triplicate, as will be detailed below. Where more than one copy of a form is made out, the duplicate is sent to the Broadway office of the company either immediately or after the repair is completed. This is done for the double purpose of giving the office a check on the operations of the service department and to insure the preservation of one copy if the other is destroyed by fire occurring in either the service department or the office. The original of this form remains in the order book of the superintendent, a duplicate is mailed to the customer whose machine has been delivered to the department, while the triplicate accompanies the automobile which is brought into the shop. The form illustrated in Fig. 4 is numbered, each set of blanks in the book bearing consecutive numbers. The specific number of the order made out is written on every form used later on in connection with that job, so that it is very easy to refer from any particular sheet or card to the general information on the job kept at the office of the superintendent. This method of marking every form pertaining to the same job with the same number makes it also easy to file all the cards and sheets together, so that they are ready for reference at a moment's notice. All files containing the records of past transactions are kept at the Broadway office, with the exception of the forms remaining in their books.

Keeping Tabs on Equipment

When the owner calls at the service department with his car, he is met by the superintendent, who takes his order for the repairs to be made. Before the car is taken from the owner, however, a detailed list of the equipment and accessories on the car is made by the superintendent or his assistant, who, for this purpose, uses the blank shown in Fig. 3. This form is white, ruled with blue lines and printed in black, and a yellow carbon-duplicate sheet follows every white blank in the book. No standard type of accessory has been overlooked in preparing this form which even specializes on Klaxon horn, electric whistle, vanity cases, etc. Three lines are left open for the detailing of the tools kept on the car. The condition of the body and the equipment is also described on this blank. The owner or chauffeur, as the case may be, goes over the record and signs it, after which he retains the carbon copy of the form.

The details of the repair work which is to be done on the car appear on the triplicate form, Fig. 4, which is filled out with the name and address of the owner, as well as the date on which the car is brought into the building. The triplicate copy is also printed on the reverse side, as shown in Fig. 5, which is a blank for recording the costs of time and material used in the repair of the car.

2. At the same time with the order, Figs. 4 and 5, when the automobile is turned over to the shop, the repair tag, Fig. 2, is attached to it. This tag is of a dark vermilion, 3 by 6 inches, and is fastened to the steering wheel of the car, with the name of the owner and the job number being clearly written on the front side. The reverse side is not printed but left blank, and on it the different repair jobs to be done on the car are enumerated. This design and use of the repair tag makes the working system very simple for the laborers who handle the repairs; further-

more the order, Fig. 4, is kept clean, as it remains at the desk of the foreman. All the workingmen have to do is to check each successive item of the work on the tag when that work has been completed.

Little Record-Keeping for Men

3. The less the men who have to concentrate on manual labor are bothered by the keeping of records, the more readily will they supply what information the company demands, while their work is proceeding. The R. & L. Company has simplified the extent to which the workingmen have to participate in the recording system, and all the writing that is necessary for them to do is done in connection with the recording of their own time and labor; consequently the men are glad to adhere to the system in their own interest. To record the time spent by the men in the shop, as well as its distribution on the various jobs, two cards, each 4 by 5 1-2 inches, are used. Fig. 8 is the ordinary clock card, on which each man stamps time in and out, during the morning, afternoon and when working overtime. This card is a weekly one, and at the end of every week the daily total times of each man are calculated and summed up to give the number of hours he worked during the week. The results are marked at the bottom of the card and the total wages paid to the man for his week's labor is also written thereon, so that the workingman, when receiving his pay, may check it against his time and sign for the money, after which the card serves as a receipt. The spaces Number and Name printed on this card have reference to the workingman. This card is kept at the office until pay-day, after which it is filed in the Broadway office.

Fig. 11 shows the time spent on individual car repairs. When a man starts work on a new repair job—that is, one on which he has not worked before—he fills out a card, Fig. 11, on which the car owner's name, that of the laborer and the job number appears. This card is also punched at the time clock and the total time spent by each man on each job is thereby determined, giving an easy means of calculating the exact cost of labor on every job passed through the shop. If any repair work should have to be done outside of the building, the time of a man's start for the work and of his return therefrom are marked on this card. This card is held by the foreman until the completion of the repair job; then it is turned over to the superintendent or his assistant.

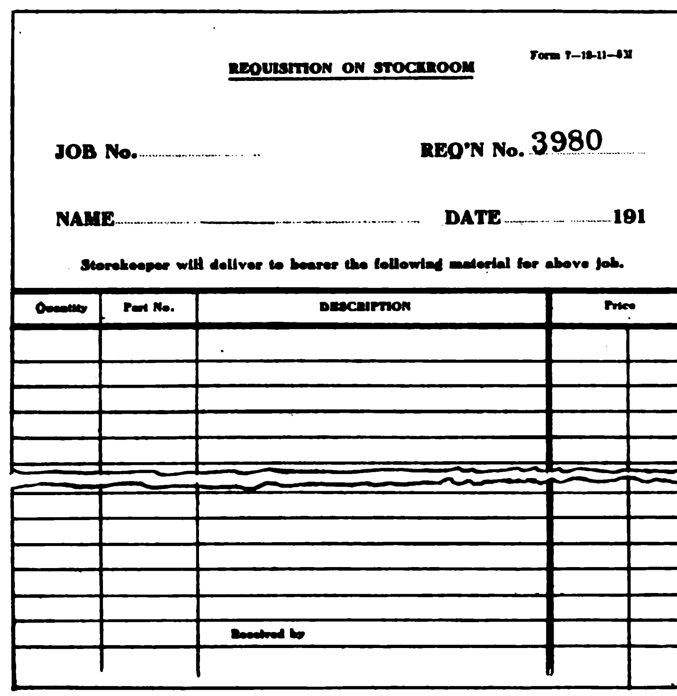
Fig. 8—Clock card of shop workers

The total time expended in the repair of a car is recorded and itemized on a time sheet, Fig. 6, which is made out from the job-time cards by the foreman of the repair shop. This sheet is 6 3-4 by 11 inches. It remains on the desk of the foreman and every morning the time records from the cards, Fig. 11, are transferred to this sheet, which is also marked with the job or order number. The foreman in filling out this blank notes the dates of the various steps of the repair, the name and number of the workingmen who did them, the number of hours spent by each man on each job, his rate of payment and the consequent cost of the labor on each step of the work. When the repair of the car is finished, the foreman totals the hours spent on the car and the cost of the labor, and, after checking once more and signing the items, sends the sheet to the superintendent of the service department, whence it passed with other blanks relating to the job, to the bookkeeping department of the Broadway office.



Form 7-18-11-8M

REQUISITION ON STOCKROOM

JOB No. .... REQ'N No. 3980

NAME .... DATE 191

Storekeeper will deliver to bearer the following material for above job.

Quantity	Part No.	DESCRIPTION	Price
		Received by	

Fig. 9—Requisition used when material is drawn from stock

4. At the time, when the time sheet is first made out by the foreman, a carbon is made of the information written on the three top lines of the sheet, the carbon record appearing on the Used-Material sheet, Fig. 1. After the sheets have thus been started, they are taken off the original pad and the time sheet, which is yellow, is kept on one file, and the white material sheet on another. Both sheets are of the same size. On the material sheet every piece of material, every pound of waste and every pint of gasoline used in the repair of an automobile are recorded, with the dates of their use, their requisition numbers and their cost.

In order to keep the stock of the service department in strict order, a requisition must be used, whenever material is drawn from the stock room, whether it be worth 1-20 cent or $15 or even more. It is a well-known fact that where the men are not used to keep track of every cotter pin or nut, they will in time permit an inexactitude to occur in the stock of more intricate and more valuable parts. The severe obligation of recording all material leaving the stockroom is founded not only on direct economic considerations, but also on moral ones which give rise to a situation of the vastest economic importance to the business. Therefore, no material must be drawn from stock without turning in a requisition. The latter is shown in Fig. 9. The method of procedure in its use is as follows: If a man requires a part or other material, he so informs a floor boy and to him specifies his needs. The boy thereupon goes to the assistant of the service superintendent who fills out the requisition, which is made in duplicate. The latter is kept by the writer of the requisition and at the close of the day is sent to the Broadway office. On the requisition appear the number of the bin in which the part is kept in stock, the nature of the part required, and the price which is charged for it to the customer. After filling out the requisition, the assistant superintendent signs it and the boy takes it to the stockroom clerk, who delivers the material to him. All the requisitions are held on a file in the stockroom until the next morning, when they are deducted from the standing stock records; after this they are returned to the superintendent's office, who later on sends them to Broadway quarters. As the requisitions are numbered consecutively and when filled out are marked with the numbers of the jobs for which the necessary material is used, a mutual control between stockroom and superintendent's records is possible for the main office of the company.

It must be remembered that no material whatever is allowed

to leave the stockroom without being exchanged for a requisition. Consequently, when a workingman goes on an outside repair job, he will in many cases be required to take along material that might be used in his work, but which may prove later to have been unnecessary and must be returned to stock. When a man goes out and takes material with him, be it parts, waste or anything else, he has a requisition filled out. If he returns with unused parts, he shows them to the superintendent or his assistant, who then makes out a customer's credit slip, Fig. 10, which comes in a pad. Then he sends the parts back to the stockroom with a duplicate of the credit slip. There the returned parts or materials are checked against the requisition, and, if necessary, the stock file is rectified. When the duplicate is returned by the stockroom clerk, the superintendent sends it to the Broadway office with the other forms relating to the repair job.

5. In case of a man doing outside work petty expenses are invariably incurred, and these are taken care of in the following manner: The man, when going out, stops at the office of the department cashier, and there draws approximately the sum which he thinks will be necessary to cover his expenses. He signs a receipt for the money given to him and goes after his work. When he returns, his job being done, he fills out an expense slip, Fig. 7, containing a detailed account of how much money was spent by him in doing his work and itemizing this statement with sufficient detail. Again the customer's name and address, the job number, as well as the laborer's name and number, are recorded, and after the man has refunded the unused balance of the money to the cashier, the latter adjusts his account and hands the expense slip to the office of the superintendent, whence it is sent to the Broadway office with the other repair job records.

6. Labor and material which are charged to a customer are distinguished from those expenses which must be borne by the company, because the repairs made were necessitated by faulty material or poor workmanship in the car; in a word, when repair work is done under the guarantee. If a part must be drawn from stock to replace a broken part on a car, perhaps outside of the service department, an exchange ticket, Fig. 12, is filled out at the same time with the requisition for taking this material from stock. Exchange tickets come in the form of duplicate blank pads. The original ticket is pink, but the carbon copy is made on light green paper. This green copy is immediately sent to the Broadway office to notify it of the necessity of doing guarantee work while the pink original is retained by the superintendent. The same time the service department now proceeds to send a man after the broken part, who takes the material with him and if necessary installs it on the car. When he comes back with the damaged part, a white tag giving the model and number of the car from which it was taken is attached to the part, which is then sent back to the factory for the purpose of crediting the department with its value. As soon as the part has been sent away, the pink slip is also sent to Broadway, so that this office may await a credit note from the factory, until which time both exchange tickets are held on a special file. The factory is also charged with the labor.

Repaired Cars Given Road Test

7. When a car repair has been completed, the service department has the car tested out to see whether the damage has been completely remedied, and to insure the perfect operation of the machine, it being important to exclude the possible

development of poor adjustments, etc., while making the repair. According to the differing nature of automobile repairs, the test made to insure that a good job has been done may be more or less extensive, as the specific conditions require; but the company prefers to give the automobile a good road test before returning it to the customer. One of the company's inspectors, an expert in the construction of the car, undertakes the test. He looks out for what necessary repairs may have been overlooked while the car was in the shop, and does what he can to tune the machine up generally to insure its good performance. When he has done this and found the automobile satisfactory, he reports at the office of the superintendent and proceeds to write out a test form, Fig. 14, which comes in a duplicate-blank pad. He fills out the upper half of the form, expressing his approval of the repairs made on the car. This having been done, the machine is ready to be redelivered to its owner, who is thereupon notified that he may call or send for his car. When the owner or chauffeur calls, he finds the car ready for operation and is invited to test it out on the road to assure himself that the work ordered has been done well. When he has done this, he signs the lower half of the form, Fig. 14, to express his satisfaction with the repair at the time when his car was delivered. Then he is made to sign the equipment blank, Fig. 3, after having looked over his car to see whether all his accessories and other equipment are there. The duplicate test form is held by the superintendent, while the original is sent to the Broadway office.

8. The above-mentioned daily report which is sent to the Broadway office is the most original feature of the entire system, in that it is a complete statement of the day's work done in the service department, and also of the number of cars received and delivered during the day for the company's new, repair, and second-hand trade. The sheet which serves this manifold purpose comes in pads, is 14 inches wide and 17 inches high, ruled in blue and printed in black. Its two sides are illustrated in Figs. 15 and 17.

Complete Day's Work on One Sheet

This statement has a double value. It puts the main office in a position of having a record of the service department's operations for every day of the week and month, without the necessity of having any of its own officers spend hours over the records and forms which are sent over daily from the service department; moreover, it forces the superintendent or his assistant to go over the whole plant at least once a day and to take such insight into the affairs of the department that no mistake can get by the records. It is this type of live reporting, done by one or two capable men, which makes a system efficient and at the same time keeps it from becoming cumbersome. The daily report sheets are filed in the Broadway office, as they come in day by day, and are always ready for reference. There they form a standing source of record indicating what the work of the service department has been for any given time and how profitable or otherwise it has been.

9. Reference to the headings appearing on the daily report sheet show that the service department also receives and deliv-

ers new cars coming from the Garford factory and second-hand machines traded in by the Broadway store. This faculty of the service department calls for forms usable in connection with the work of handling these cars. When they arrrive at the service department, the assistant of the superintendent makes a memorandum of the car's number and equipment, which he keeps on his desk, no special form being used for this end. After noting the number and model of the machine on the daily report sheet, the machines are turned over to stock. When any automobile is delivered to a buyer from the service building on the orders of Broadway quarters, the assistant of the superintendent fills out a delivery order or card, Fig. 13. These cards come loosely, like the time cards. The assistant superintendent gives the name of the purchaser, the sales order number which he receives from the Broadway office, and the date on which the machine is to be delivered. Then the details describing the car and its equipment, the number and model of the chassis, as well as a detailed account of the accessories carried on the machine, are entered on the delivery order, enumerating the most general accessories. The back side of the order is a short inspection blank containing the following items: fill oiler, fill radiator, gasoline, grease cups, tune motor, adjust brakes, which are checked by an inspector before the car is delivered.

Records Filed at Main Office

10. In this operation the receipt, Fig. 16, is used. The name of the purchaser, date of delivery and details regarding the car and its accessories are written on this form, which is made out with a carbon copy on yellow paper by the assistant to the service superintendent. When the owner or his chauffeur calls at the department, he signs the original and carbon copy of the receipt and retains the latter, while the former is sent to the Broadway office together with the delivery order. Both forms are filed there under their sales order number.

It has been stated above that when a repair has been completed, all the forms used in connection with it are sent to the Broadway office, to be filed there under the job number which first appears in Fig. 4. The forms which are sent together to the main office are herewith summed up: Figs. 1, 4, 5, 6, 7, 9, 10, 11 and 14. The repair tags, Fig. 2, are all kept by the superintendent and are filed by their job numbers. The inventory, Fig. 3, stays in the book it came in. The clock cards of the workingmen, Fig. 8, after having been gone over by the foreman, are sent to the bookkeper's and cashier's office for settlement at the end of the week. Exchange tickets, Fig. 12, are kept on a special factory credit file at the Broadway office. Figs. 13 and 16 go to the sales file of the main office. The daily report, Figs. 15 and 17, is kept on a special file in the main office for future reference.

This system requires the full attention of the assistant of the superintendent, as well as that of the stockroom clerk and the foreman, the latter two, however, doing other work in addition thereto, so that only one special man is necessary. The R. & L. Company stores and serves about threescore cars. The consequent cost of service per car is very low and the saving proportionately great.

Suggests Machine for Testing Brakes—Right and Wrong Methods of Attaching License Plates—Light on Dyer Patent Situation—Removing Carbon from Manifold—Lubricating the Clutch—Running on Advanced Spark

Recommends Brake Testing Machine

EDITOR THE AUTOMOBILE:—I read with interest the article on brake efficiency and materials in your last issue, and in connection therewith would like to give some details of the methods employed in the Hudson factory in brake construction. We use fabric brake linings in which asbestos is interwoven with copper wires. The coefficient of friction is between 0.25 and 0.40. Our brake diameter, 16 inches, with 4 inches width of face. The car is able to stop in a distance of 35 feet when running at a velocity of 20 miles per hour. A very desirable feature of the present brake linings which are now on the market would be a greater conductivity of heat.

In my opinion, axle manufacturers are in a position to carry out experiments on their brakes, regarding their resistance moment, and it would be desirable if they would specify the results on their drawings. To calculate the retarding moment gives very uncertain results. Such calculations involve too many variable quantities and factors, such as the friction coefficient, and the action of cams and differential levers.

Obtaining the result by calculation, this way, it will never give the designer a near enough correct value of the brake moment, and to know this exact value it would be necessary to know the braking moment at the time when they select a certain set of brakes for their car. Of course, it would be still better if on their drawings they would furnish a character curve of the brake. This curve should indicate the increase of the moment, with the increase of the load applied on the end of the tightening system. The point of such a curve could be easily determined by a simple testing machine. The design of such a machine should be something like the following: A flywheel resting on two ball bearings and on one end of the shaft is connected with the hub of the rear axle. The other end carries a clutch which enables us to disconnect the motive power; also it has a sensitive tachometer. During the experiment it would be well if the gears on the differential and also the bevel gear were removed. To obtain the different readings, different weights should be applied on the end of the tightening lever. Then the calculation of the moment would be the following:

G = the weight of the flywheel concentrated in the center of gravity of the section of the flywheel.

r = radius of this point.

t = uniform length of time interval in which the revolution is recorded and in this interval the disk makes a revolution of n and in the following interval it makes a revolution of n_1.

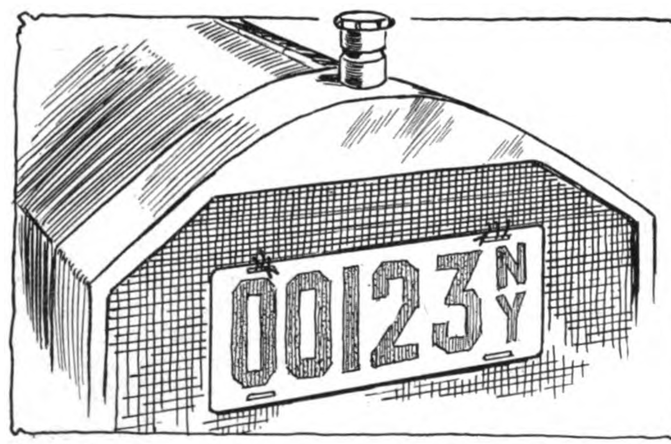

Fig. 2—This way of suspending license plate means radiator breaks

The mean angular velocity during the first interval is

$$\frac{2.\pi.n}{t}$$

and during the second interval is

$$\frac{2.\pi.n_1}{t}$$

then the retarding moment in the t = time interval on a body which has a moment of inertia $G \times r^2$ — is equal to

$$M = \frac{2.\pi\ (n - n_1)\ G.r^2}{G.t^2}$$

This moment is due to the friction coefficient, f.

If r_1 = brake radius, then

$$f = \frac{2\pi\ (n - n_1)\ r^2}{g.t^2.r_1}$$

where $g = 32.2$.

This way, knowing the character of the brake moment, we could easily establish the rate of retardation due to the road resistance, because the variation of road resistance could be measured by the accelerating condition. This is given by the motor output because at top speed the motor output equals resistance. The total retardation of a car

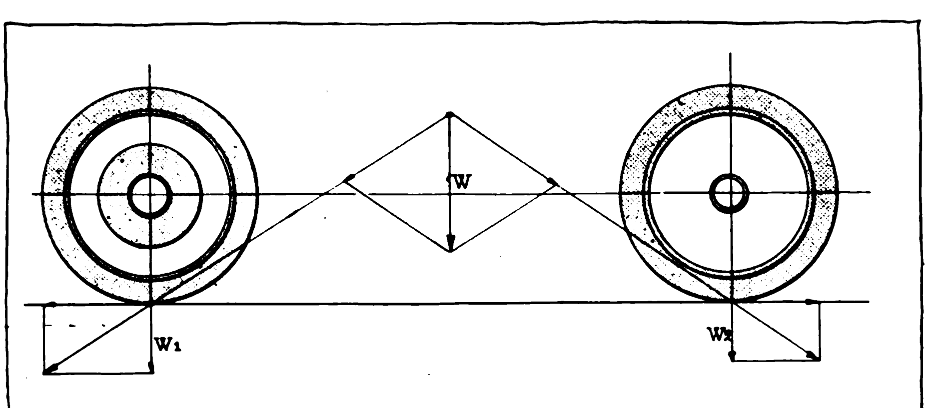

Fig. 1—Illustrating distribution in adhesion in front-wheel braking—car standing still

is the sum of the retardation due to road resistance plus retardation due to the brake. These two acting on a distance treatment is the work done by retardation. When the brakes are thrown into engagement, the capacity of doing work against retardation is

$$\frac{MV^2}{2}$$

foot-pound per second. Consequently the distance traversed during the action of resistance is

$$\text{Distance} = \frac{MV^2}{\text{Mean resistance}}$$

To know the character of resistance would also be important in a case of transmission brakes. Here the disk running on a higher speed gives a larger friction surface than in the rear brake. The resistance of a correctly designed transmission brake should not be greater than the torque of the motor on low gear. I found that many transmission brakes give an overload on the rear axle pinion bearing as high as 300 per cent., which is decidedly harmful even if it acts only for a short length of time. The same requirements hold good on brakes on the jackshaft.

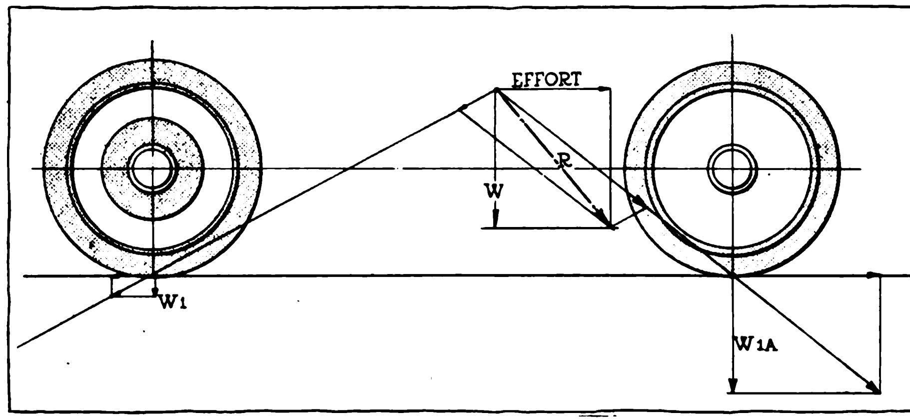

Fig. 4—Diagram illustrating increase of adhesion of front wheels with car in motion

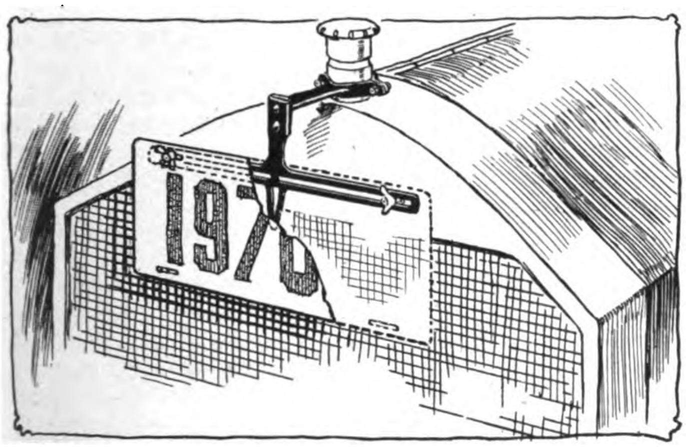

Fig. 3—Safe method of hanging license—radiating surface not lessened

In regard to the future of front wheel brakes: These have one disadvantage; this is the comparatively complicated brake shoe operation. Its advantage lies in the fact of the change of the adhesion on the wheels. Individual sets of brakes should have a retardation near to the locked wheel condition. The car, at rest, by the distribution of the weight has a larger adhesion generally on the rear according to the location of the center of gravity. Fig. 1.

While the car is moving, Fig. 4, the adhesion on the rear axle changes, due to the fact that the driving effect and the weight of the car is acting on the center of gravity. These two forces give a result of R, shown in Fig. 2. This R decomposed in the contact points of the wheel will give an increase of adhesion on the front. Consequently, the front wheel in the early part of retardation is able to carry a larger brake moment, as in the rear and at a lower speed, the adhesion again increases on the back axle. Therefore, the front brakes give a quicker rate of retardation as a correctly designed transmission brake, with a rear axle brake, would give.

Detroit, Mich. S. J. Fekete.

Care in Hanging License Plate

Editor The Automobile:—What is the best way to hang a license plate? I wired mine to the radiator and have practically ruined the latter.

New York City. Subscriber.

—Many licenses are carried by car owners in the manner shown in Fig. 2. The wires are run through the openings in the radiator and passed through the holes in the license plate. When the car passes over road obstructions it shakes the license plate causing the wires to break down the structure of the radiator.

The plate should be hung in some such manner as by the bracket shown in Fig. 3. In this way the radiating surface is not cut down and a much neater appearance is made. When the license plate is put on such a holder, however, the owner should remember the following important point: Always have a leather or rubber washer between the thumb screw and the enamel or the latter will start to chip and before long a large amount of the surface will snap off. The same point should be remembered in attaching plates to the rear brackets.

Concerning the Dyer Patents

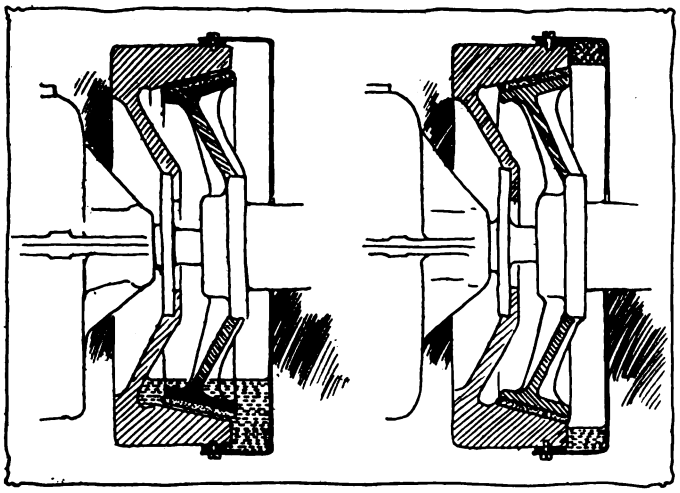
Editor The Automobile:—As an owner of an automobile I received a notice from Dyer, Dyer & Taylor, attorneys, calling attention to infringements of the Dyer change-gear patents. In your issue of The Automobile, page 1315, June 13, you make mention of individual licenses being issued. As an automobile owner I am interested in the proposition, as I feel sure are other owners as well, and I for one would like to know where I stand and what is to be done. Possibly in some previous issue of The Automobile you covered this subject, and if so I failed to see it. If not, why not let your readers know just where are their rights in the matter and what to do should they receive these lawyers' notices of alleged infringement?

New York City. An Automobile Owner.

—The Dyer patents, referred to in your letter, were duly granted by the Patent Office and at this time are in process of adjudication in the United States District Court. There are but two courses open to an automobile owner in your predicament. First, to disregard the notice and second, to take out a license. If you follow the second plan, the matter is settled at once. If you disregard the notice and the complaining party pursues the usual course, suit will be filed in the United States District Court asking for an injunction, accounting and damages.

Any attempt on the part of The Automobile to forecast the action of the United States District Court touching any matter pending before that court would be the height of impropriety. The patents in question have not been adjudicated, but all patents carry with them a presumption of validity until the contrary is shown. Therefore, it would be in bad taste for The Automobile to prejudge or anticipate the action of the court in any patent case.

The present status of the suits brought under the patent is inconclusive. Four main suits against the Locomobile, Maxwell, Winton and Saurer respectively are now before the court as well as several scores of individual suits. The four suits referred to above are being defended by William A. Redding, but no answer to the original complaint has yet been made. When this answer is filed, proof of the patent will be taken in due form and the



Figs. 5 and 6—Showing novel method of lubricating clutch

facts upon which the defense relies will be put in. The testimony will then be submitted to the court and arguments will be heard on both sides. The opinion of the court will be rendered and in such an important matter it is reasonably certain that no matter which side prevails, appeal will be taken to the United States Circuit Court of Appeals. Ordinarily this court is the tribunal of final resort in patent matters and its decree will be accepted as the law of the land on the particular measure involved.

It is conceivable, however, that the Supreme Court may accept jurisdiction of the cause after decree by the United States Circuit Court of Appeals.

Before decree, the patentee, or his assigns, may proceed against alleged infringers irrespective of pending suits.

In the Selden litigation, it will be remembered, suits against individuals were filed; licenses were granted and proceedings in court prosecuted during the pendency of the basic or main suit against Henry Ford, *et al.*

When the Selden suit was overthrown in the United States Circuit Court of Appeals and the limits of the patent sharply outlined, the decision of the court served to check further proceedings against defendants whose cases involved the same facts covered by the decree.

In case suit is filed against you, if your attorney puts in an answer and takes advantage of all the chances for delaying a hearing that the case is susceptible of, it may be that in the meantime the main suits will be tried and in case the defense prevails, there is a chance that your suit will be dismissed without coming to trial. This should be considered in no wise advice from The Automobile, as the whole question is one for the automobile owner to answer for himself.

Kerosene and Water to Remove Carbon

Editor The Automobile:—Do you believe it a good idea to introduce by way of petcock in the manifold between the cylinder and carbureter kerosene while the engine is running? In some publication I noticed an article that kerosene and water in alternate doses would remove carbon. Do you think this a good practice?

Amsterdam, N. Y. H. L. Reed.

—According to the idea expressed in this communication the petcock would be located in some such position on the manifold as is shown in Fig. 7. It would be very difficult to find many manifolds that would be suitable for such an application of the petcock on account of the vertical riser which would be prohibitive of placing the cock directly on the manifold, although it could easily be accomplished by the aid of an elbow. While the scheme would doubtless work very well, as it would allow the operator to put the kerosene into the cylinders while the motor is running, which is a very desirable feature, yet, if the kerosene is placed in the regular compression cocks on the top of the cylinder as soon as the motor is stopped it will be sufficiently warm to vaporize the kerosene and in this form allow it to reach its maximum efficiency as a solvent.

The introduction of water into the manifold at this point is a matter which should be approached with great caution and it is difficult to see where the benefit of its use would be felt. The petcock would compel the use of another joint in material which has not been especially bossed to take the thread of the plug and which is not of sufficient thickness to be proof against a leak where the difference in pressure on the interior and the exterior of the manifold is very high. On the whole, it would seem more satisfactory to introduce the kerosene in the manner which has been previously described. That is, on stopping the car to put a compression cupful of kerosene into each cylinder and let the car stand overnight. When starting, open the petcocks for a while and blow out the accumulated matter.

A Unique Clutch Lubricator

Editor The Automobile:—I have a suggestion to make for slipping clutches, without the use of cushion springs, and would like your advice on same.

It is a plate screwed on the rear face of the flywheel enclosing the clutch. It can be put on a gasket and has a hole in the center, large enough to take the clutch hub. This plate will form an oil-tight reservoir in which clutch oil can be put to a certain level. I claim that this oil will lubricate a small portion of the leather facing of clutch for starting. Then when the motor starts, centrifugal force will cause the oil to spread into the form of a ring and entirely leave the clutch face, so that it can become dry again for transmitting power without slipping. I am driving a car with this type clutch and have had no trouble with slipping when using castor oil. I think this scheme will take away the only fault of the cone clutch. It will also keep out the dirt. (Figs. 5 and 6.)

Cranford, N. J. Harold L. Collins.

Wants to Build and Equip a Garage

Editor The Automobile:—Could you give me an estimate as to what it would cost to put up and equip a garage suitable for general repair work such as you would have to do around a summer and winter resort? I do not want a large storage room. I would like to put in a small lathe, drill press and emery wheel run by a gasoline engine. I would like to keep a small stock of supplies such as would sell readily and would pay. If you could give me an idea of what it will cost and as to how it should be managed and also stocked, I would be greatly obliged to you.

Jackson Springs, N. C. Robert B. Cochran.

—The following equipment will probably be sufficient for your needs: A small lathe, $175; drill press, $60; emery wheel and other small tools, $25; a vulcanizer, from $15 to $50 varying with size; small gasoline and oil outfit, $300; car-washing arrangement, $10 to $15; crane, $80; gasoline engine, $100. The prices for machinery refer to second-hand goods, procurable in any large city. Regarding the cost of erecting a suitable building it is

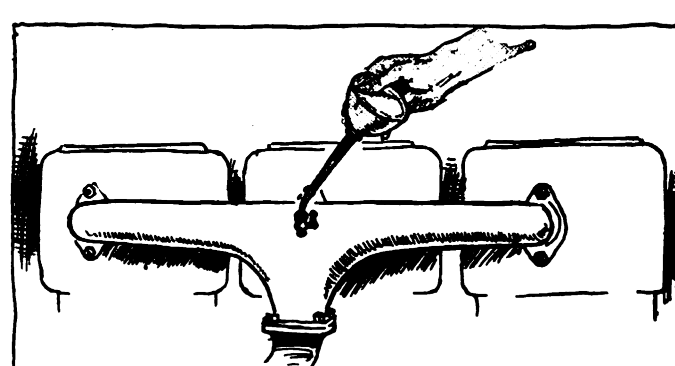


Fig. 7—Petcock on manifold for injecting kerosene to remove carbon

hard to say anything definite as it varies very much with its size, the material of which it is constructed and local conditions, so that it will be necessary for you to address a local contractor for a bid. Methods of conducting the business of a garage have repeatedly appeared in THE AUTOMOBILE, and the articles in the issues of April 18, 1912, and May 16, 1912, should prove of interest to you. If you have in mind to carry a small stock of supplies and accessories, this should principally include one or two good makes of tires in the most called-for standard sizes, tire repair outfits, oils and greases, spark-plugs and the like.

Pierce-Arrow Wiring Diagram

Editor THE AUTOMOBILE:—I have a 1912 Pierce-Arrow, 48-horsepower model, which is of the six-cylinder type. Can you give me the correct method of wiring the double ignition system and the proper order of firing the cylinders?

West Chester, Pa. AMATEUR.

—In Fig. 8 the wiring diagram of the double ignition system is shown. The order in which the cylinders should fire is 1, 5, 3, 6, 2, 4; therefore the binding posts of the magneto spark-plugs in these cylinders should be connected to the distributer plugs marked 1, 2, 3, 4, 5, 6 respectively; that is, 1 on the distributer to cylinder 1, 2 on distributer to cylinder 5, etc. The spark-plugs for the magneto are in the cylinder heads. The second ignition system uses a storage battery and individual unit autocoils with a master vibrator. The connections are also seen in Fig. 8, together with the leads to the acetylene headlights, where dash-control of the illumination is used.

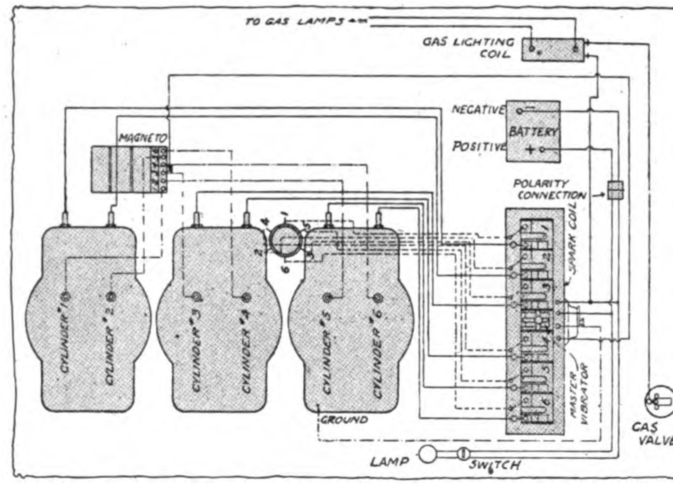

Fig. 8—Wiring diagram of Pierce-Arrow double-ignition system

From Detroit to Delhi, Ont.

Editor THE AUTOMOBILE:—Will you kindly give me the route from Detroit, Mich., to Delhi, Ont.; also the road conditions and what is necessary in taking an automobile into Canada.

Chicago, Ill. SUBSCRIBER.

—The best route to follow from Detroit to Delhi, Ont., is 611R of the Blue Book, which leads from Detroit to London, Ont., whence route 612 leads to St. Thomas, 40 miles from Delhi. The distance from Detroit to St. Thomas by the routes mentioned is 159.8 miles. In making this tour start from the Soldier Monument, Detroit, setting odometer at zero. Follow Woodward avenue trolley northwest and cross International ferry, 0.3, after which proceed to Windsor, Ont., to corner of Oulette avenue and Sandwich street. When meeting trolley turn to the left, then to the brick-laid road on the right, leaving the tracks into Glangarry avenue. From six-corners, 1.3, after meeting trolley car, turn to right into Howard avenue, crossing the railroad tracks at 2.4, 3.0, 3.1, 4.5 indications on odometer. At 9.3 cross railroad at Old Castle Station, then at Maidstone station, 12.8. Join trolley and cross tracks at 17.2, passing through Essex at 17.3; the trolley leaves to the right at 23.2. At 28.0 passing blacksmith shop, turn to the right, then at 28.6, at the end of the road to the left; then to the right with poles. At 30.4 enter Ruthven, turning to the left around the hotel and pass through Leamington, 34.1, and Wheatley, 41.9. Turn to the right at 46.1, and to the left with the poles at 46.5, proceeding on the curve to the left, 50.4, and to the right, 50.5. After taking the next curve to the left and then the right-hand road with the poles, observe caution in rounding curves along the lake, 58.6. Passing through Cedar Springs, 68.6, and crossing the railroad at 71.8, go through Blenheim, 72.6, thence to Ridgetown, 82.5. At 85.9 reach diagonal four corners and turn to the left across two railroad tracks, then into the next right-hand road, to arrive at Highgate, 88.9. At four corners, 91.2, turn to the left, then to right at 91.7. At the next four corners turn left, 92.3, reaching Clachan, 96.6, whence proceed to long iron bridge which is crossed at 103.8 and come to Wardsville, 104.1. Pass through Wood Green, Strathburn, Melbourne to Delaware, 128.9, turning to the right when reaching the church and at three corners, 134.2, turning to left, following sign "London." Pass through Lambeth, 141.2, across the iron bridge into London, 142.0. Start from there, corner Richmond and York streets, and follow the trolley across the bridge, at end of road turn to left on Wharncliff road, pass under Grand Trunk railroad and run straight ahead, bearing to right at 145.4 and entering Lambeth. Then turn to left with trolley line, crossing the iron bridge at 149.5 and the railroad tracks at 157.5. Just before railroad viaduct turn to left at 159.1, turn to right into Talbot street, St. Thomas, 159.8. There inquire of natives for direct route to Delhi.

Using Light Oil in Gearbox

Editor THE AUTOMOBILE:—I have about 15 gallons of oil on hand which is not heavy enough for my machine. What ingredients should I add to convert it into a suitable transmission grease?

Hollywood, Cal. T. J. BOSSERT.

—The oil can be mixed with any grease or non-fluid oil which will give the resulting compound sufficient body to have the requirements of a satisfactory gear lubricant. The result should be a soft paste.

The primary qualification of a gear lubricant is that it shall be of such composition that it will adhere to the surface of the teeth in spite of heavy pressure being placed upon it. When the power is transmitted from one gear to another the whole energy of the motor is distributed over the driving faces of the teeth and unless the viscosity of the oil is sufficiently high the lubricant will be squeezed out and rapid wear will result.

The oil which is drained from the crankcase of a motor may be used over in the gearbox when mixed with grease in the same manner as described for the light cylinder oil. It will have a waxy residue, which spoils it for cylinder use, but makes it desirable for the gearset in that it clings to the tooth surface.

Running on Advanced Spark

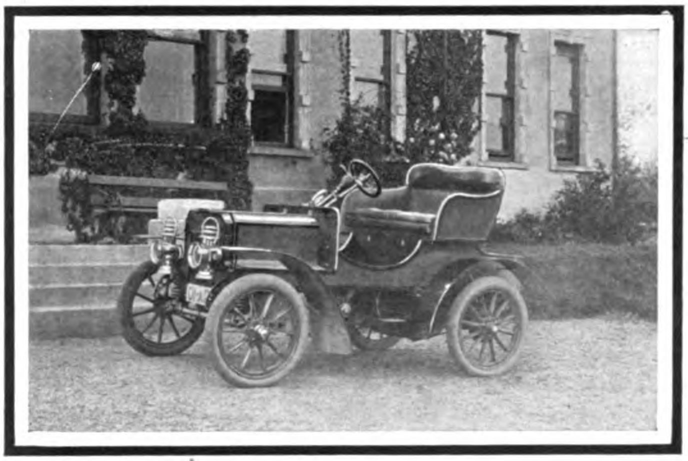
Editor THE AUTOMOBILE:—We have four chauffeurs, two of whom are unusually good mechanics, one with 15, the other with 9 years' experience. The car used occasionally by all four is often out of order. One claims it is best to run on advanced spark, another claims this method injures the machinery and claims that it is best to run on retarded spark.

Will you kindly give your opinion and oblige an old subscriber.

Fieldhome, N. Y. CORTLANDT DE P. FIELD.

—The best economy and results are secured when the spark is advanced as far as possible without the slightest knock. This is the opinion of expert drivers, and it is backed up by results over measured courses with given quantities of gasoline. It is doubtless slightly easier on the machine to retard the spark a trifle further than this, following the idea that the ear is not sensitive enough to catch the knock as soon as it develops.

If the spark is advanced until the knock is heard and then retarded until the knock just disappears and then one notch further the results will be about right.



First car ever made in Ireland—a Chambers

Motor Trade in Ireland

Nearly 10,000 Cars in Use in the Emerald Isle—Good Field for American Automobiles

What to Avoid in Seeking Business—Only One Factory on the Island, but More Coming

DUBLIN, IRELAND, Aug. 5—Although there are upwards of 9,000 automobiles in use in Ireland to-day, the manufacture of this class of cars in the Emerald Isle at the present time is confined to a single factory, located in Belfast. An additional motor-car factory is, however, to be built in Dublin in the near future.

The automobile has long since become an indispensable fixed factor in Ireland, not alone for pleasure traveling, but as a commercial carrier. There are about thirty different makes of commercial cars in use in Ireland at present.

Ireland's business firms make use of great numbers of lorries and vans for the carrying on of commerce. This is highly practicable, for the reason that of the country's 54,000 miles of public roads, at least 50,000 miles are in splendid condition for traffic and the county councils are making them better daily by the application of the steam-roller. Hundreds of these machines are in active service.

The advent of the railways in Ireland resulted in much neglect in the upkeep of the public roads. Again, by reason of the old Grand Juries act, a bar was placed upon every description of power-propelled road-making machinery prior to 1898. But all of that is passed and Ireland is an ideal country for motorists and for the carrying on of motor traffic.

The fire brigades both of Dublin and Belfast have fallen in with the progressive idea. The type of motor fire-engine used in both cities, is identical. Very soon Cork and Londonderry will also be able to boast of a motor fire brigade.

Automobile drivers are well paid in Ireland. The speed laws are not tyrannical, and accidents are surprisingly few.

Quick Production No Advantage

There are but two American types of automobiles to be found in any number in Ireland. But the average Irishman who is in the market to buy a car wants to see it demonstrated; he wants to be able to purchase parts of the local dealer; and he will not be driven from the long-established custom of asking and receiving credit. Another thing, American agents traveling over here (one in particular gave moving picture demonstrations) do their level best to impress upon the Irishman that the American-made car is built rapidly. The Irishman shudders at the very thought. His first impression is that a car made hastily cannot be good. There is no use trying to break through conventionalities. It is better to say nothing about the time required for the production. Such talk only has a tendency to frighten the Irishman and spoil a sale.

Ireland today affords one of the best opportunities of any country in the world for the sale of automobiles. The country has awakened. It is prosperous. Its farmers are getting rich. They get as much per pound for butter and bacon as do the American farmers. The exports from this country last year amounted to more than $325,000,000—$72.50 per capita of population—making her the fifth exporting nation among eighteen. Ireland's people are buying luxuries, notably automobiles. But they cannot see that it adds anything to the quality of a car to prove that it was manufactured within a few hours' time. The history of the nation has convinced them that things to be desired are secured only after long and patient endeavor. They have not yet been educated up to the point where they can see the virtues of quantity production. In the accompanying illustration is shown the first automobile ever manufactured in Ireland. It is of the vintage of 1904, and was built at the Chambers works in Belfast. It is of the two-cylinder type and registers 7 horsepower. Everything about it, with the exception of the tires, was made in the Emerald Isle.

Other Foreign Opportunities

AUTOMOBILES FOR GERMANY—A big American company, which recently established an automobile agency in Germany, sold 10 cars during the first 3 months. Most of the machines are for pleasure purposes, but one is being used as a taxicab. An American Consul writes that there are persons in his district who are willing to form a $50,000 company for importing American cars, but they desire the general agency for Germany or for all Europe if possible. They are looking for a four-seated car that could be sold for about $1,000. American firms interested in this proposition may secure information by writing the consulate in question. File No. 9196.

SMALL MOTOR TRUCK—An American manufacturing company writes to the Bureau of Manufactures that one of its customers in a Latin-American country is interested in purchasing a small truck, with two seats in front and a space of about 5 1-2 feet behind, with cover, to carry a total weight of about half a ton. What is desired, therefore, is something in the nature of a runabout, but with the truck attachment described. Manufacturers interested in this should submit printed matter and prices f.o.b. vessel New York. File No. 9236.

LOW-PRICED AUTOMOBILES—A business man in a Mediterranean country informs an American consular officer that he desires to secure the exclusive agency or representation in that country of some American manufacturer of automobiles. An automobile of the touring type that will cost not more than $800 f.o.b. New York is what is desired, and for this type a considerable market exists in the country in question. The inquirer desires illustrated catalogues, prices, discounts, and terms of payments. He can furnish satisfactory references and correspondence may be in English, Italian or French. File No. 9240.

AUTOMOBILES—A foreign business firm advises an American consul that it desires to purchase an American automobile costing from $800 to $1,500. Catalogues and prices, with shipping weights, are desired, and if possible the freight rate from port of shipment to city of destination, either *via* Hamburg or the Pacific coast. Correspondence and printed matter can be in English. File No. 9234.

IF a motor 'bus breaks down in a London street and repairs are made in the street which cause inconvenience to the general traffic, it is within the power of a constable to take action against the driver for neglecting to have the 'bus towed to the nearest garage.

Big Paris Show Prospects

Nearly a Dozen American Cars Will Be Represented in Addition to Many Accessory Makers

Three Trade Associations Will Run the Exhibition on a Profit-Sharing System

PARIS, July 26—Nearly 30,000 square yards of exhibition space have been applied for in connection with the next Paris motor show to be held in the Grand Palais, Paris, from December 7 to 22. Every available inch of space has been booked and there is a big waiting list of firms hoping to get into the exhibition by the withdrawal of those already given stands. This year's show, the thirteenth of the series, is distinctive by reason of the large number of American firms taking part. The United States motor industry is represented by Cadillac, Buick, Case, Century, Flanders, Ford, Hupmobile, Mitchell-Lewis, Oakland, Reo and Overland. American accessory manufacturers are generally represented by French agents, who show the products on their own stands and under their own names. Among those having distinct stands are Rushmore lamps, Klaxon, Acheson Oildag, Werner Speedometers, Vacuum Oil Company. Only one American tire manufacturer will be represented at the show, this being the Goodrich concern, exhibiting through its European house. American machine tool manufacturers will be represented by Potter & Johnston. Among the few electric vehicles will be those of the Anderson Electric Car Company. This list of American concerns exhibiting at Paris is evidence of the important position the United States manufacturers are securing on the European market, for when the last show was held in Paris, 2 years ago, the only American-built car on exhibition was the Ford.

With every available inch of space booked up, the French manufacturers anticipate a bumper show. The increase has been brought about by the larger number of home firms wishing to compete, and by the increased applications from America and England. Up to the present English manufacturers have not considered it advisable to take part in the Paris Salon, especially as the French exhibition followed very closely after the one at Olympia. For the first time this year many of the leading British manufacturers have applied for space, among the more important being Argyll, Austin, Coventry Chain Company, Daimler, Hele-Shaw, Humber, Napier, Rolls-Royce, Star, Sunbeam, Vickers, Wolseley, and a number of accessory and tire makers.

The Paris show is now a purely manufacturers' concern, being organized by the three leading trade associations and run under a profit-sharing system. All exhibitors are entitled to share in the profits, although those belonging to the trade associations participate undler more favorable conditions than outsiders. Stand positions are to be awarded by the drawing of lots, foreign exhibitors taking part under the same basis as the home firm, provided their own show organizers give equal facilities to French firms.

Congress of Material Testers

THE sixth congress of the International Association for Testing Materials will be held at the Engineering Societies Building the week of September 2-7. Delegates from every country in Europe except Turkey and a few of the less important states, several Asiatic nations and the United States have been named and it is expected that the congress will bring out a very representative, cosmopolitan gathering.

The Society of Automobile Engineers will be represented by Past-President Henry Souther. The technical program so far arranged includes 170 papers and at least thirty-five of Ameri-

Besides the regular sessions, the business of the congress will include trips to West Point and about the city and suburbs and at its conclusion the delegates may take a swing around the eastern portion of the country. A special train has been arranged for the party, leaving Sunday afternoon after the end of the deliberations and stopping at Washington long enough to allow of an inspection of the public buildings, Bureau of Standards and testing laboratories. The trip is scheduled to cover Pittsburgh for 2 days, including visits to the steel, cement, electric and explosive factories. From Pittsburgh the party will go to Buffalo and Niagara Falls, returning to New York on September 14.

The officers of the organizing committee of the congress are as follows: Henry M. Howe, president; Robert W. Lesley and Robert W. Hunt, vice-presidents; Edgar Marburg, treasurer; H. F. J. Porter, secretary, and W. O. Wiley, treasurer of the executive committee.

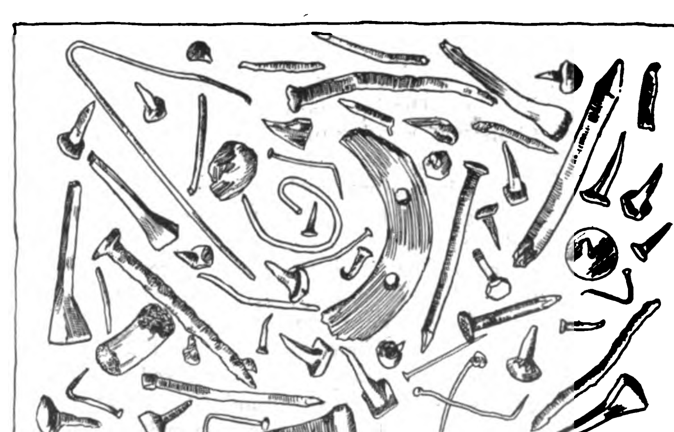
Two Boston Companies Go Under

BOSTON, MASS., Aug. 12—The Selbach Rubber Company, a Massachusetts corporation doing business at 404 Columbus avenue, has assigned. The assignment was made to Walter Powers, but no estimate has been made of the value of the business or the amount of the indebtedness.

Frank H. Coyne, doing business in Boston and New York under the name of the Detroit Tool Sales Company, and the Portable Machine Shop Company, an automobile accessory, made an assignment last week. He owes $95,405, of which $95,201 is unsecured among about 200 creditors. The creditors are scattered throughout the country.

Tire Shoe as a Junk Repository

About sixty bits of metal, as shown in the accompanying illustration, were picked up by the left rear tire of a Cadillac car in service on the London streets during the course of 1,000 miles. The owner of the car, a friend of A. Staines Manders, general manager of the International Rubber Exposition, which will be held at the Grand Central Palace from September 23 to October 3, was so impressed with the number of tire destroyers that he picked them out of the tire and had them photographed. Mr. Manders was so much interested in the demonstration of the danger to tires in London that he presented the picture to THE AUTOMOBILE. The curious part of the story is that the tire did not suffer a single puncture and the owner did not know that his tire was accumulating a load of metal until one day he was forced to extract the bit of horseshoe, shown in the middle. This did not cause a puncture and neither did the accession of the wire and wire nails. The thing that did the business was the small nail, shown at the lower right-hand corner and when it reached the vital spot, the shoe blew out for 22 inches. The tire tread and fabric had been so weakened by the repeated stabs that after the blow-out occurred the whole shoe was useless.



Collection of junk picked up by a tire in London

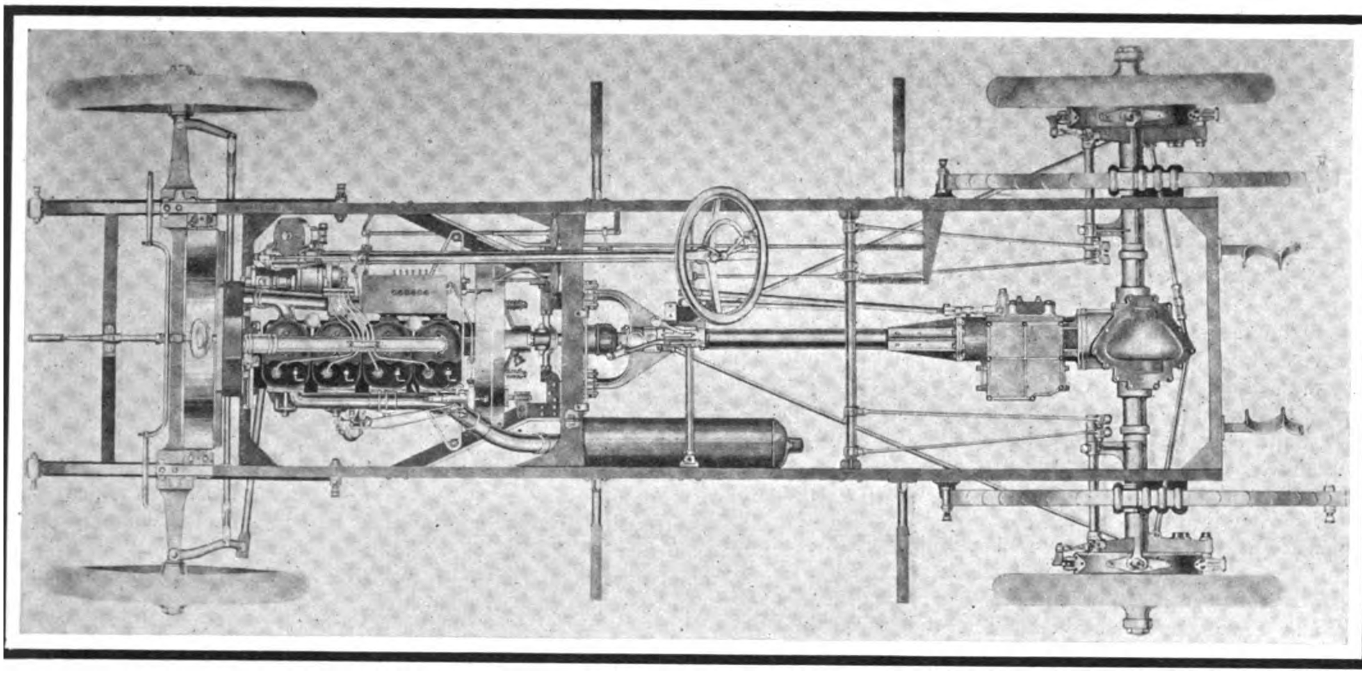


Fig. 1—Plan view of chassis of model 69 of the 1913 Overland line, showing location of gearbox

Two Models of 1913 Overland

While Characteristics of Line Are Retained, Quite a Number of Refinements Are Noted

Cylinders Are Cast Separately—Gearbox Is Located on Rear Axle—Eight Body Types Offered

THE Overland line for 1913 consists of two models, as for 1912. These are to be known as models 69 and 71, and replace models 59 and 61, respectively. A number of changes and improvements have been incorporated in the two, but on the whole they retain all the characteristics of the Overland construction. The gearboxes are located on the rear axles, motors have their cylinders cast separately, and while a number of changes have been made, these are principally refinements and do not alter the general Overland features.

Model 69, the less expensive of the two cars, is still the leader and its construction will be taken up first. The motor is a four-cylinder, L-head type; each cylinder is separately cast, as brought out in Fig. 1. The bore is 4 inches and stroke 4 1-2 inches, giving a horsepower rating of 30. The stroke-bore ratio is 1.12 and for this reason the motor will develop more than its rated power. As heretofore, cooling is by thermo-syphon system with a cellular radiator. The water capacity is about 4 1-4 gallons, and the total weight of the water in the cooling system 34 1-2 pounds. The maximum temperature reached by the cooling water is given as 198 degrees. The thermo-syphon cooling system obviates the water pump and is considered to be absolutely automatic. It is claimed that the speed with which the cooling water circulates is increased or decreased with every corresponding change in the power demand. In the Overland system, the water enters the lower ends of the cylinder jackets on the opposite side of the motor from that shown in Fig. 3. On becoming heated, due to the explosions within the cylinders, the water becomes partly steam and rises to the tops of the jackets entering the outlet manifold, and thence flowing into the radiator where it is brought into contact with the large cooling surface.

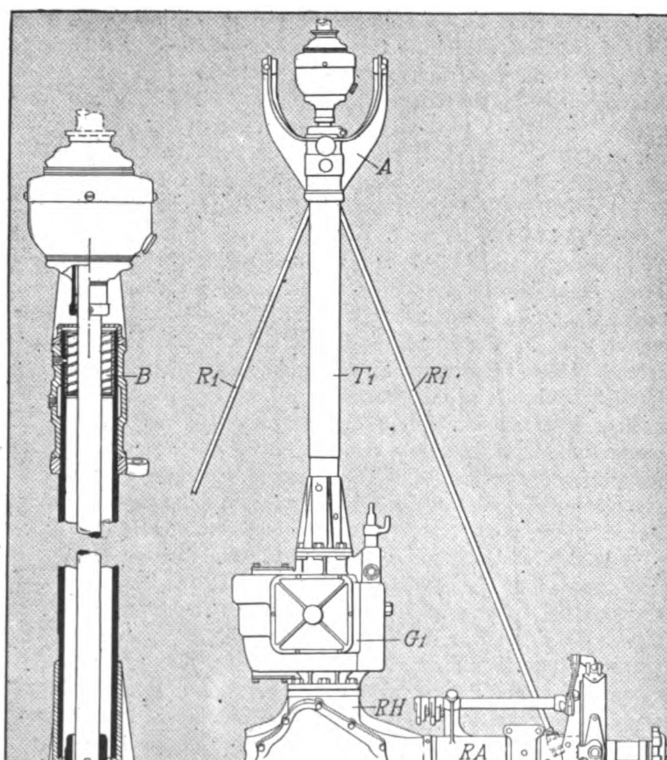

Fig. 2—Plan of Overland transmission and rear system

As to the mechanical construction of the motor, the pistons have a length of 4 1-16 inches and are fitted with three rings each. Improvement has been made in the pistons in that oil grooves under the lower rings have been added, each with six drain holes equally spaced around the circumference to keep excess oil from the piston heads.

The motor bearings are all of a babbitt which is an alloy of tin, copper and antimony. The various bearing sizes are given below:

CRANKSHAFT—FIVE BEARINGS—Length rear bearing, 3⅛ inches; diameter, 1½ inches. Length of other four bearings, 1¾ inches; diameter, 1½ inches.
CAMSHAFT—THREE BEARINGS—Front: 2 5-16 or 2 7-16 inches long; diameter, 15-16 inch. Center: 2 3-4 inches long; diameter, 15-16 in. Rear: 2 1-16 inches long; diameter, 15-16 inch.
MAGNETO SHAFT BEARINGS—Length, 2 1-8 inches.
CONNECTING ROD BEARINGS—Piston ends: length, 1 3-4 inches; diameter, 7-8 inch. Crankshaft ends: length, 1 3-4 inches; diameter, 1 1-2 inches.
WRIST PIN BEARINGS—Length, 3 3-4 inches; diameter, 7-8 inch.

The crankshaft and connecting-rods are of carbon steel, drop-forged. The wristpins are cold-rolled steel, hardened and surface-ground. The crankshaft steel has the following properties: Three per cent to 4 per cent carbon, 4 per cent to 6 per cent manganese, not over 4 per cent phosphor of sulphur, an elastic limit of 90,000 pounds per square inch, and an ultimate strength of 100,000 to 110,000 per square inch.

The properties of the camshaft steel are the same as those of the crankshaft, with the exception of the carbon content, which is from 1 1-2 per cent. to 2 1-2 per cent. carbon.

Details of Valve Mechanism

The valves, Fig. 3, have a clear opening of 1 9-16 inches and are of nickel steel, the dimensions being as follows: Diameter of head, 1 13-16 inches; length of stem, 5 3-8 inches; length of push-rod guides, 2 3-8 inches; length of push-rod, 3 1-8 inches; diameter of push-rod, 1-2 inch.

The valve tappets bear directly on the cams, which are integral with the camshaft. On the push-rod guides new oil-retaining washers have been placed.

The lubrication is a combined splash system for the crank and camshaft bearings and mechanical Kinwood force-feed oiler for the cylinders and timing gears, as shown in the top view, Fig. 1. Ignition is by model RL Remy magneto and battery and model LE coil. This furnishes two sources of current. A change in the intake manifold has been made; it is now flanged instead of being threaded so that the carbureter may be removed without taking off the manifold. The Schebler carbureter has been retained on all models. The fuel is fed by gravity.

The clutch is of the cone type and leather-faced. This applies to both models. Power is transmitted from the clutch to the gearbox, which is placed at the rear, through a propeller shaft having a diameter of 1 1-8 inches. A view of the transmission system after it leaves the motor is shown in Fig. 2. The propeller shaft is enclosed in a torque tube T-1 which has a U-shaped arrangement A at its forward end where it fastens to the cross-member of the frame. As in the usual construction, two radius rods R-1 run from the forward end of the torque tube to the rear axle. The gearbox G-1 is bolted directly to the rear axle housing RH. A cross-sectional view of the transmission gears is given in Fig. 3. The gearset is of the three-speed selective type, the gear ratios being as follows: High, 1 to 1; intermediate, 1.55 to 1; low, 2.57 to 1; reverse, 3.30 to 1.

The rear axle, R.A, Fig. 4, is of the three-quarter floating type, whereas this model for 1912 was equipped with a semi-floating rear axle. The bearings are of the Hyatt roller type, as shown at B, Fig. 2. The length of the ends of the bearings is 1 9-16 inches, while the differential bearing has a length of 2 inches. The axle shafts are 1 1-4 inches in diameter, the left half LS having a length of 32 5-8 inches, and the right half 33 3-8 inches. Brakes BR are increased in size over those of 1912, their diam-

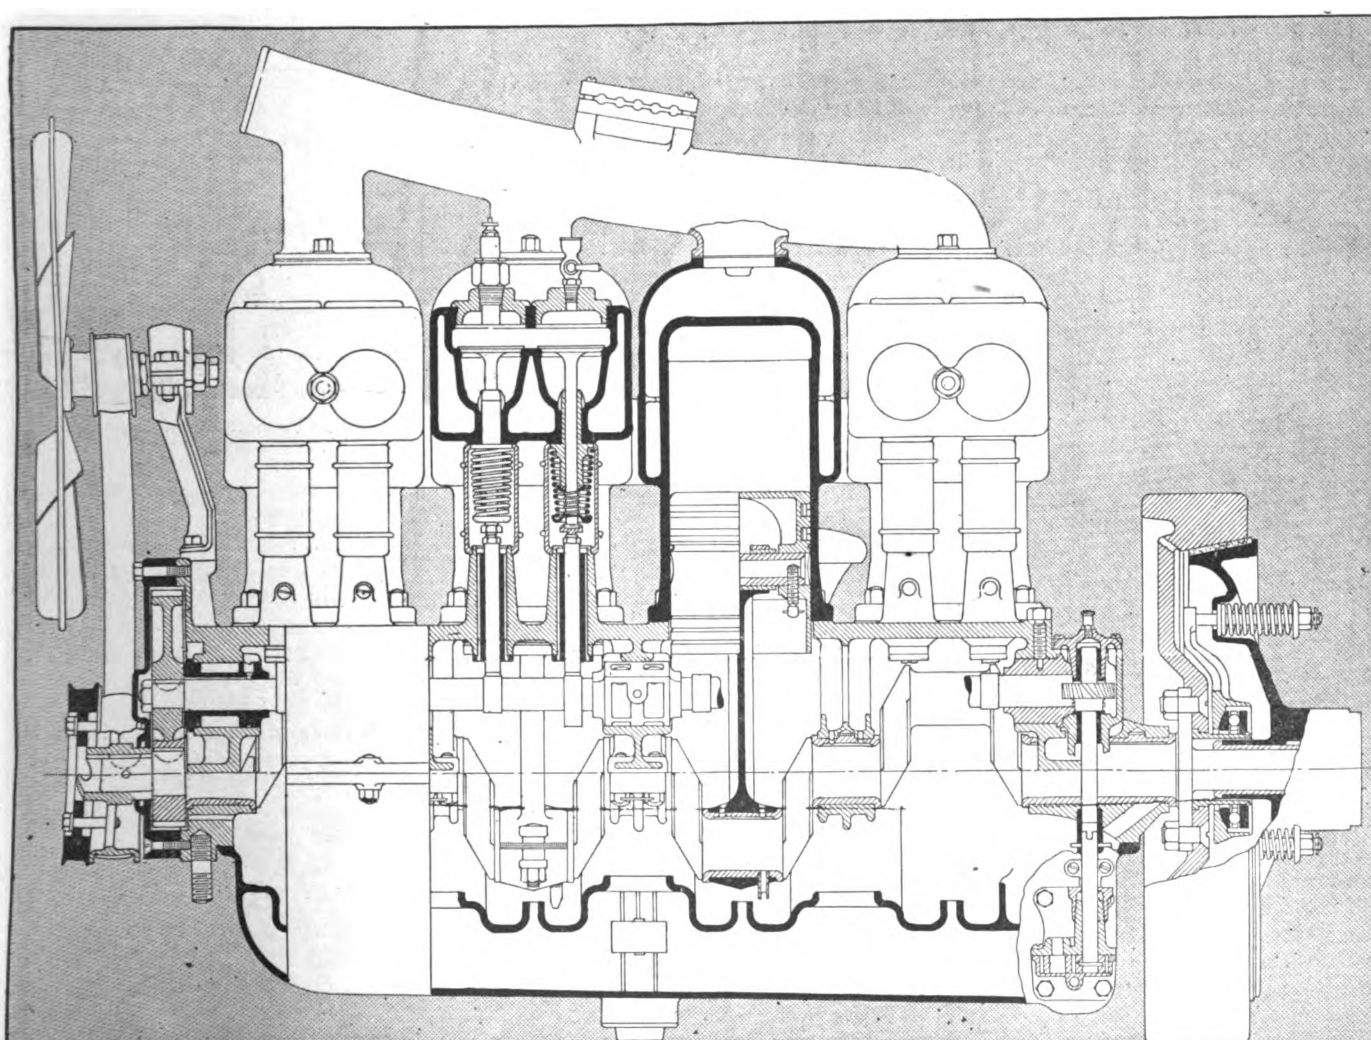

Fig. 3—Side part sectional view of the motor of Overland model 71, showing single-cylinder castings

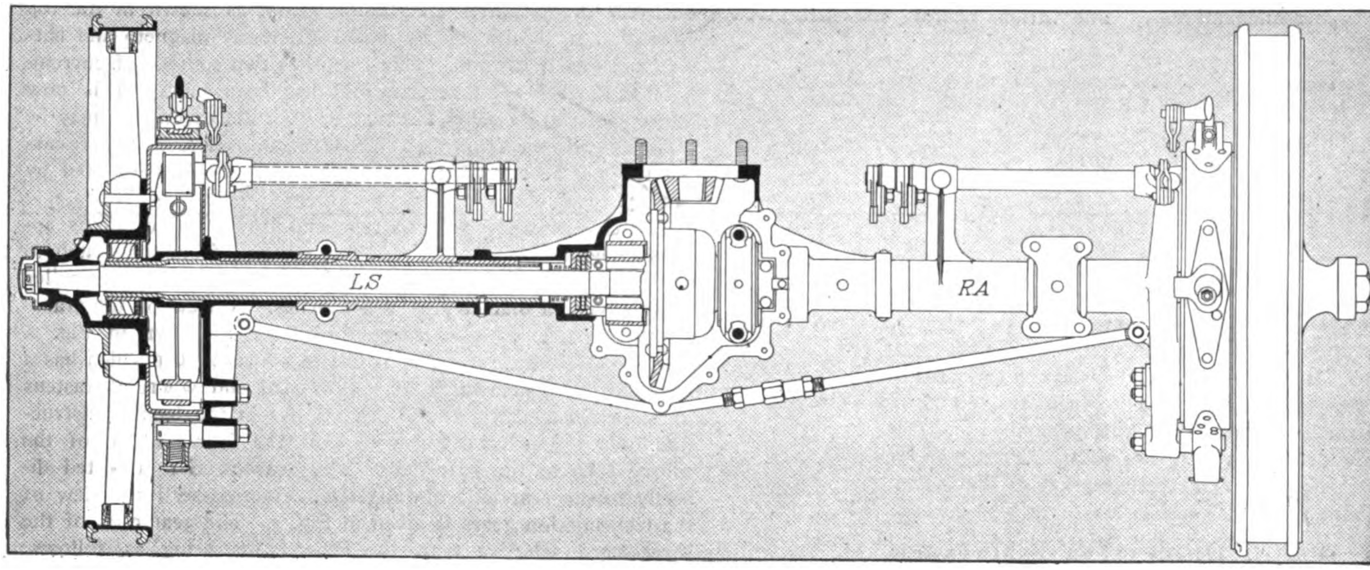

Fig. 4—Three-quarter type of floating rear axle used on 1913 Overland line

eter being 13 inches and width 2 1-4 inches. They are of the conventional external-contracting service and internal-expanding emergency types, their construction being shown clearly in the illustration herewith. The brake equalizing arrangement has been much simplified. Instead of the two operating shafts used on the 1912 models the new cars are equipped with a brake operating mechanism which consists of a tube and a shaft on which the equalizer parts are mounted. The arrangement of this new equalizing device is shown clearly in Fig. 8. Both service and emergency equalizers are at the right side of the frame and are fitted with special springs.

The frame is of cold-rolled steel channel section, No. 9 U. S. gauge. This has a thickness of .156 inch. The depth of the side members is 3 3-4 inches and the flange face width 1 1-4 inches. The frame is well braced with three cross-members, in addition to the brake member which acts as an additional brace. The front cross piece is a little forward of the front axle, while the second one is just to the rear of the motor, the torque tubes, fastening to it. The third cross member is at the rear. The motor is hung in a form of sub-frame and has one supporting cross piece in front and one at either side in the rear. These rear supports run diagonally from the side frame members to the cross member at the rear of the motor and the crankcase arms bolt to them at about their centers.

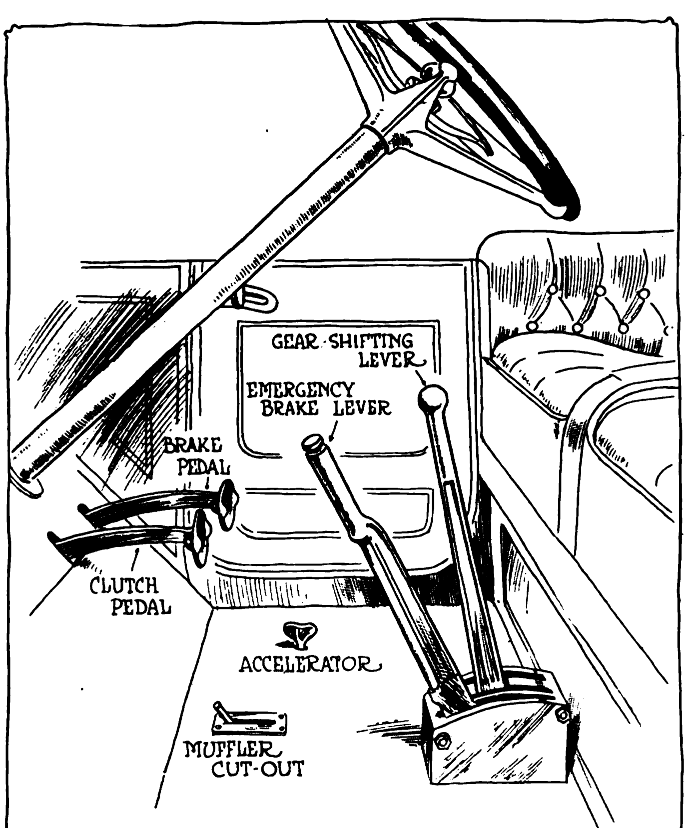

Fig. 5—Drive features of the 1913 Overland, showing center control

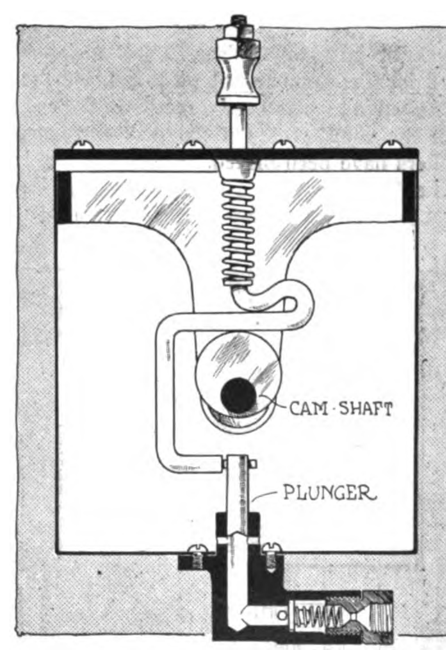

Fig. 6—Section of mechanical oiler used on model 69

The front axle is drop-forged of the usual bowed-center I-beam type, and affords a road clearance of 10 1-2 inches. Springs are all constructed with six leaves and are fitted with steel bushing eyes. The front springs are half elliptic, while the rear are elliptic. The spring sizes are as follows:

Front: Length, 36 inches; width, 1 3-4 inches.

Rear: Length, 42 inches; width, 1 3-4 inches.

The steering wheel is on the right with the control levers in the center. Spark and throttle levers are on top of the steering wheel on the usual type of quadrant.

Wheelbase Increased on Model 69

The wheelbase of model 69 has been increased from 106 to 110 inches on all models. For the touring car the extreme length is 168 inches with the top down, and for the roadster 151 inches. The wheelbase of model 71 is 114 inches.

As to model 71, this chassis is practically the same in design as the other, except for the difference in size of the various parts, as has already been brought out. The motor, a sectional view of which is shown in Fig. 3, has a bore of 4 3-8 inches and a stroke of 4 1-2 inches. The rating is 45 horsepower. It will be seen that its features do not vary materially from those of the other motor. The oiling, however, is entirely by splash with a pump for maintaining constant level in the crankcase. The ignition and cooling systems are similar to those on the model 69 engine. The various motor dimensions are given below:

CRANKSHAFT—FIVE BEARINGS—Front: 1 7-8 inches long; 1 1-2 inches diameter. Three center: 1 3-4 inches long, 1 1-2 inches diameter. Rear: 4 3-8 inches long; 1 1-2 inches diameter.
CAMSHAFT—THREE BEARINGS—Front: 2 11-16 inches long; 1 inch diameter. Center: 2 3-4 inches long; 1 inch diameter. Rear: 2 1-4 inches long; 1 inch diameter.
MAGNETO SHAFT BEARING—2 1-8 inches long.
CONNECTING ROD BEARINGS—Piston ends: 2 1-4 inches long; 1 inch diameter. Crankshaft end: 2 1-8 inches long; 1 5-8 inches diameter.
WRIST PIN BEARINGS—4 inches long; 1 inch diameter.
VALVES AND PUSH-RODS—1 7-8 inches clear opening; 2 1-8 inches diameter of seat. Push-rods: 4 1-16 inches long. Push-rod guides: 3 3-8 inches long.
FLY-WHEEL—17 inches diameter; 3 1-4 inches width.

Like model 69, model 71 has three-speed selective gearset, the gear ratio being as follows: High, 1 to 1; intermediate, 1.72 to 1; low, 3.2 to 1; reverse, 3.93 to 1.

This gearset is also mounted at the rear axle. The latter, however, on this model is floating, while that of model 69 is three-quarter floating. The transmission dimensions are:

REAR AXLE—Differential bearing, length 7-8 inch. End bearing,, length 7-8 inch.
AXLE SHAFT—Diameter, 1 5-16 inches; length, right 32 13-16 inches; left, 32 1-16 inches.

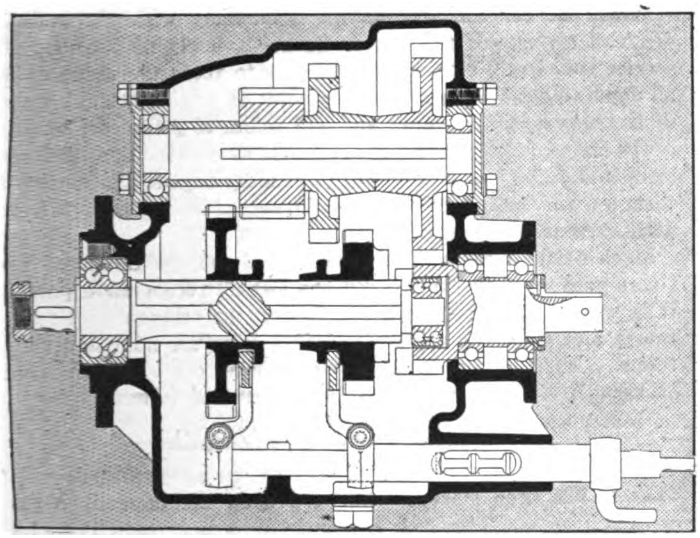

Fig. 7—Cross-section of the 1913 Overland gearset

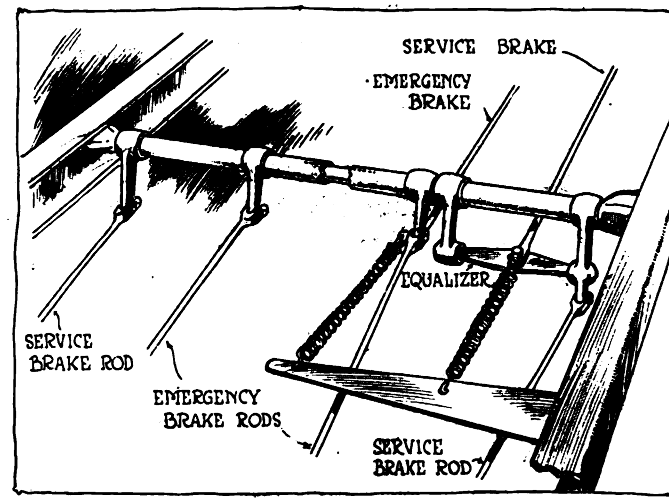

Fig. 8—Showing new brake equalizing arrangement on Overland cars

PROPELLER SHAFT—Length, 41 inches; diameter, 1 1-8 inches.
GEARSET MAIN DRIVE SHAFT—Diameter, 1 13-16 inches; length, 12 7-16 inches.

The same scheme of inclosing the drive shaft in a torque tube and bracing is used on this model as on model 69. Brakes are also identical in every respect on the two models.

As to the wheel sizes, those of model 69 are designed to take 32 by 3 1-2-inch tires on quick detachable rims, front and rear, while on the 71 the tire size is 34 by 4 inches.

Wide Range in Body Design

Eight body types are fitted to the two chassis. These consist of touring cars, roadsters, four-passenger models and coupés. The bodies have all been deepened and lengthened, while the seats have been made deeper and lower. Increased leg room has been provided in the tonneaus. As to the five-passenger touring car fitted to the model 69 chassis, this has a divided front seat and its front cushions have a width of 18 inches. The cushion depths are also 18 inches. The rear seat cushion has a width of 46 inches. The doors have been made amply wide, and door handles are placed within. The model 69 two-passenger roadster has also been somewhat changed to give it added distinctiveness and more rangy appearance.

Model 71 bodies are similar to those furnished on model 69, but being more expensive are, of course, somewhat more refined. Running-board tool boxes and kits are provided, which

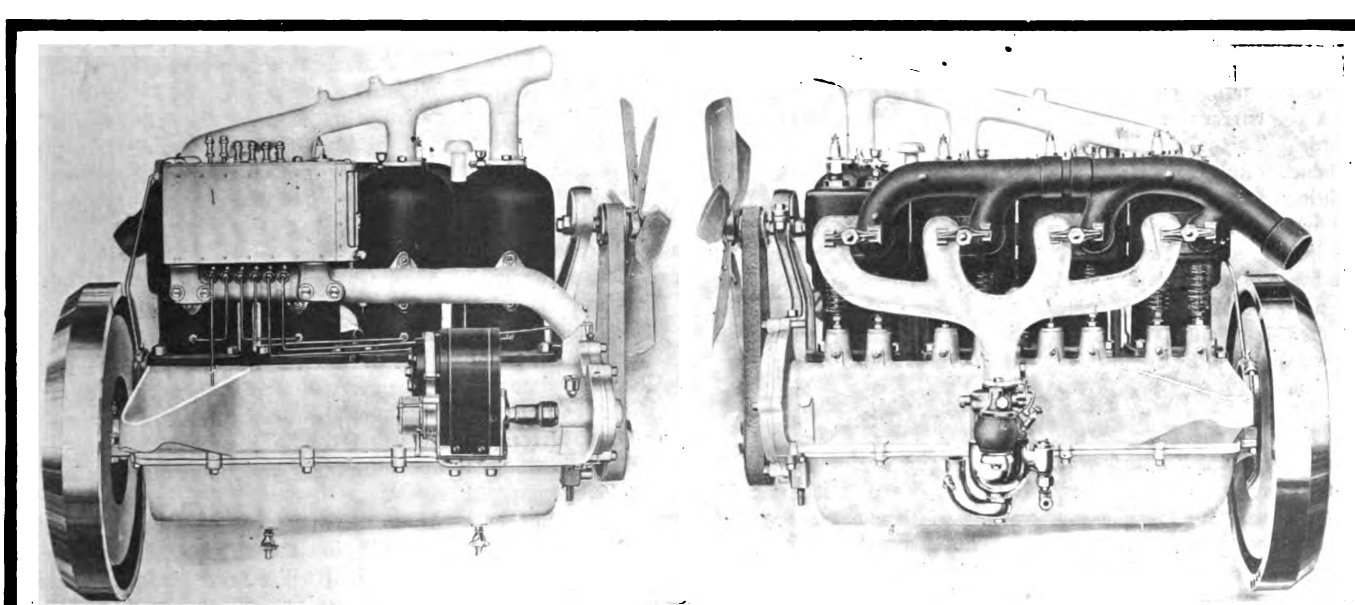

Fig. 9—View of both sides of the model 69 Overland motor, showing magneto, carbureter and mechanical oiler

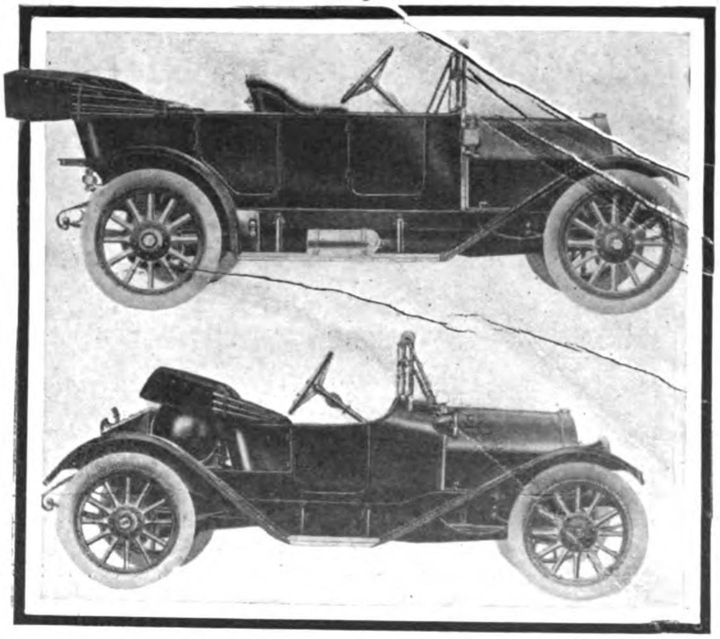

Fig. 10—Model 69 touring car and model 71 Overland roadster

give the clean running-board appearance, and at the same time afford ample room for all supplies. The roadster does not have these running-board boxes, but there is a slanting-top box mounted at the rear of the seat back of the gasoline tank. Tire irons are provided on top of this rear tool box on both roadsters.

The price for model 71 has been fixed at $1,475, while that of model 69 is given as $985. The $85 increase in the price of the cheaper model is accounted for by the fact that model 69 carries full equipment, while model 59 for 1912 did not. The 1913 model has a mohair top and top envelope, windshield, speedometer, gas tank and self-starter as added equipment, compared with what its predecessor carried for its price of $900, so that the new model is really cheaper when everything is considered.

All cars this year with the exception of the coupés are fitted with Prest-O-Starters, which operate in connection with the Prest-O-Lite acetylene gas tanks, and the construction and operation of which has been explained in previous issues of The Automobile. The coupé models, when so ordered, are fitted with self-contained electric starters, the motor-generators of which take the place of the flywheels. This starting apparatus is manufactured by the United States Light & Heating Company, of Niagara Falls, N. Y. The device also furnishes current for lighting all lamps.

Electric lighting is a standard equipment feature of model 71 cars, the current for these lights is furnished by a lighting generator. This operates in connection with a storage battery. Whenever the car's speed is in excess of 10 miles an hour, the lighting current passes directly from the generator to the lamps, but when there is more current produced by the generator than the lights require, the excess passes to the storage battery. This condition obtains in the day time when the lamps are not lighted. At a speed of about 18 miles an hour, the generator produces its maximum current of 10 amperes. An ammeter on the dash shows the condition of the current in the system.

Cold Is Not Good for Tires

It is well known that heat and light and decidedly injurious to tires, but a thing not so widely known is the fact that cold is quite as harmful to tubes and casings if they are exposed for a long time to a low temperature. The effect of cold upon tires is not unlike that of cold on other substances; iron pipes burst in extreme cold; tires first begin to harden, then lose their resiliency and finally become fragile and crack. This shows the advisability of keeping tires in a dark, dry place, with a uniform temperature of about 60 degrees Fahrenheit.

Revarnishing The Car

Carefully Touch Up the Bad Spots with Proper Color Before Beginning the Operation

Chassis and Mud Guards Will Need Renovation, Too—Advisability of Coloring Brass Parts

After treatment of water baths, renovators, surface elixirs, varnish restorers and the other liquid contraptions has been exhausted and the varnish refuses to longer respond to the cleaning and "doctoring," it is high time that the car be turned over to the painter with the admonition to "tune her up."

Varnish reaches a day when coating and renovating methods and even the prayers of just men no longer avail. In this emergency the automobile painter comes to the rescue and with much necessary cleaning and fussing and the application of paints and varnishes in adequate measure makes the car look like new throughout.

When the car comes from the paint shop with the radiant depth of the mirror reflected in its finish, it begins a course of service sufficiently erosive in its nature to fetch the depth of it all down to a mere glaze, at which point of decline nothing short of touching up and revarnishing will suffice to please the owner.

The days of the motor car finish are, as a rule, comparatively brief and full of trouble. It is constantly exposed to a varied form of service which includes doping, cleaning and rubbing until eventually it succumbs.

Much of the cleaning and rubbing and the application of revivers goes on after the varnish has lost all recuperative power. It is without any capacity to feed upon the cleaners and renovators, and show any appreciable effect from the nourishment.

Such a surface is even a bad one to bring out under one coat of varnish, a single coat being insufficient nourishment.

Preparing Surface for Varnish

The surface, in fact, may be described as varnish-hungry. It has been starved while fed upon the dope of cleaners and feeders. This lack of nourishment is in most cases inexcusable. The car owner should know, even if he should be invited to sit at the feet of the painter and learn, that after 6 or 8 months' wear in the strife of modern service, maltreated and scrubbed until its life has been threatened a score of times, the average car varnish is in a condition to be replaced.

To be sure, comparatively few cars get the fresh coat of varnish, but this neglect simply adds emphasis to the statement that they all should get freshened up with a new supply of luminous material considerably oftener than the present practice provides for.

To renew the finish by adding a single fresh coat of varnish is not an expensive treatment and it should not take the car long out of service.

To condition the finish in this way proceed about as follows:

Do as little unhanging of the car and its parts as possible Clean the interior of the car out well and cover with a piece of canvas or other like material. Wash the body thoroughly in order to determine the exact condition of the varnish. There will be grease spots upon the body and upon the chassis which should be removed with waste saturated with turpentine. Failing with this, rub with a strip of broadcloth rolled up in the shape of a cylinder, after dipping the roll in water and pulverized pumice stone. This method will remove the grease spots in short order. Then rub the surface all over with a felt pad dipped in water and pumice stone flour. This treatment clips off the motes of dirt and makes everything clean and smooth to receive the new coat of varnish.

Naturally, there will be spots in the color that will need touching up and matching up with the old color. This is an operation that very few men can perform successfully. The car owner may be quite as adept in getting the color tone and shade as the painter, and in some cases more so, merely because he may possess color sense, without which no one need hope to succeed in the work.

The eye for color is a gift, not an acquirement. In touching up confine the work to precisely the spots worn or nicked off, or disfigured in other ways. Touch only the blemish, and do not let the color splash over parts of the surface in perfect condition. It's very rarely the case, to be candid, where the match of the new color with the old is so perfect that it cannot be detected. For this reason touch only the diseased or imperfect surface space.

This work now having been attended to, the next step consists of applying the varnish. No one but the experienced painter or varnisher can hope to do this work upon the fine and beautiful surface of the motor car with any degree of success. It requires professional skill and brush expertness, and an intimate knowledge of varnish in all its fitful moods, to flow the surface and cause it to look like a mirror from Paris.

Touching Up Chassis and Fenders

The layman may paint his car, but when he comes to varnish it, that is quite another story.

The finishing coat of varnish should always be flowed on plentifully. Lay it out with brush strokes lengthwise of the panels, cross brush, and again brush it lengthwise of the panel surface. All this appears very simple, and it really is so, but there is the practice and the know-how back of it.

Bring the chassis along in practically the same way that the body surface is attended to. In touching up both body and chassis preparatory to varnishing observe this rule invariably: Use the color with sufficient varnish in it (added after thinning the color with turpentine) to cause it to dry with a gloss. The theory of this is that the color with strong luster to it reflects more light than it absorbs, in which case, in drying out, it does not change in tone or shade, whereas the color containing no luster, and drying dead, as the term is, absorbs enough light to not infrequently change it a shade, and perhaps several shades, from what it appeared to be in the mixing kettle.

The fenders or mud guards should, of course, be brought along with the body of the car. The lamps and brackets, etc., if in color, should get at least a coat of varnish color or enamel, and if a baking oven is handy this varnish color or enamel should be baked on.

If of polished brass, the parts will need polishing up, but if such parts have been lacquered it will be necessary to first remove the lacquer. This may be accomplished by mixing 1 pound of caustic soda in 3 gallons of water and applying to the brass with a soft wool sponge tied to a stick. Use this solution with care and avoid smearing it on other parts of the surface. Rinse off with clean water, after which treat it with some good metal polish. All of the brass parts after cleaning and polishing should be coated over with lacquer or lacquer substitute, which latter may be made by thinning pale elastic automobile body varnish with turpentine or by using a thin coat of white shellac.

Lacquered brass becomes dirty and discolored through use and often appears tarnished when in fact it is merely dirty. Rubbing smartly with metal polish under a woolen cloth will remove the dirt and restore the surface to its original condition.

The advantage of having these parts finished in some selected color, blue, green, black, maroon, and so on, is that they may be maintained in presentable condition at less expense than in case of the brass finish, and in the matter of refinishing the cost is considerably less. Moreover, from an artistic standpoint the color finish, if in harmony with the field color of the car, loses nothing by comparison with the blazing brass surface.

The varnished car is not complete until the radiator has been brushed, and cleaned, and treated with a thin coat of asphaltum, bronze, graphite or some dark mineral paint qualified to stand heat and wear hard and long. No thick or heavy-bodied pigment should be used on the radiator and the car owner may wisely insist upon the use of only very thin coats of material for these parts.

Attention should always be given the top as the car goes through the shop. If only a mohair top, it deserves a brushing to eradicate the dust and dirt and bring out the good points of the material. As a rule, the car top gets about the worst sort of neglect.

For the dirty leather, rubber or Pantasote top, the outside finish requires washing with a weak solution of castile soap. In course of time if the leather or rubber becomes worn and looks permanently "dingy" it should have a thin application of some reliable dressing, formulas for which have been given in previous issues of THE AUTOMOBILE. The bows of the top need a finish to correspond to other parts of the car. They should be cleaned perfectly from impressions of the hands, and finally, before recoating, washed off with turpentine. Then coat them in with a clean, full application of varnish color. In the event of the bows being found "nicked," and the finish fractured and possibly chipped off somewhat, a coat of flat color should first be put on, the varnish color to follow.

Too Many Patents Issued

Commissioner Moore Says That a Large Percentage of Them Should Not Be Granted at All

With $500,000 the Office Could Guarantee Novelty of Every Patent Issued

WASHINGTON, D. C., Aug. 3—There are no industries in the country more vitally interested in the matters pertaining to the United States patent office than the motor car and accessory industries. To all those connected with these industries it will come as a distinct surprise that Commissioner of Patents E. B. Moore has come out with a statement to the effect that a large percentage of patents issued by the patent office should not be issued at all. Commissioner Moore made this declaration in discussing the proposed investigation into the methods and personnel of the patent office.

Indorsing all the claims made by Representative Bulkley, as to the needs of the patent office and the evils which it is alleged exist in the department under his charge, Commissioner Moore said that a half million dollars would remedy every existing abuse and place the office on a modern business footing, under which the government could guarantee the novelty of every patent issued. Commissioner Moore defended the men who work under him, but he admitted the truth of the statement that no sooner had a man been trained to some position with the patent office than he would move into some business for which his training had fitted him, and which paid him double and often treble the government salary.

"I would not care to say 50 per cent., but a large percentage of the patents which are issued from this office are not good patents and should not be issued," said the commissioner. "Yet what can one do under the condition with which we work? We have not the men nor the equipment to conduct the searches and it is only natural that a great deal should be overlooked, which would not be the case if we had the improvements for which I have asked during the past five years. If these things are granted to us, it would enable the patent office to make the search so thorough that the government would be able to guarantee at least the novelty of the patent, as is done by the German government. Then the patentee can be sure that his patent is at least original.

Fig. 2—Packard 38 Little Six runabout

Packard Announces 1913 Little Six

Left Drive and Control; Positive Starter, Combined with Electric Lighting and Ignition Are Features

Convenient Control Board on Steering Column Within Easy Reach of Operator's Hand

THE Packard Motor Car Company will have for delivery within a month a small six-cylinder machine, which will be known as model 38. It will be furnished in any desired body type at prices ranging from $4,050 for the runabout to $5,400 for the imperial limousine, which has seating accommodations for seven. The touring car and phaeton types will be sold at $4,150. The wheelbase of the touring car chassis is 134 inches; of the phaeton, 138 inches, and of the runabout, 115 1-2 inches.

While in general appearance and most details of construction the new six conforms to previous Packard design, several of its features are decidedly new to cars of this make, and they mark what might be termed a new Packard era. These more or less noticeable changes from the details which have been accepted as part of Packard cars of the past are the adoption of left-hand drive and control, electric self-starting, and the distinctive feature of using a control board mounted on the steering column, which carries all the switches and buttons connected with starting, ignition, lighting, as well as the carbureter adjustments.

The left-hand drive and control feature is perhaps the most significant change which has been made and marks the entrance of this company into the ever-increasing ranks of the left-hand drive users. The reasons given by the Packard company for this adoption on its newest creation are that it did not wish to adopt the left drive until it had developed a starting system which would be positive, since the car operator would have to get out into the road to crank his motor and might just as well go the rest of the way around the front of the car to get into the driver's seat. But now that it feels that it has added a starter which is positive, there is no reason why left drive should not be used, since the driver is now enabled to reach his seat and start the motor without stepping into the road.

Combined Starting, Lighting, Ignition

The starting system, of the Delco type, is in combination with the electric lighting and ignition systems. The outer rim of the flywheel has teeth cut in it, with which the gear of the electric motor-generator meshes when the crankshaft is to be revolved by electric energy for starting. The motor-generator is normally a generator, and runs only temporarily as a motor when required for starting. This electric system has been taken up in detail on several occasions in these columns, but a brief description of its operation will not be out of place here.

In addition to the combination of electric system there is a set of dry cells, which are used only for furnishing ignition current when the motor is first started. After the engine is running, the operator switches to the generator current. The reason for the use of this auxiliary set of dry cells is that in starting the storage battery is drawn upon to furnish energy for operating the electric starting motor, and should this battery be required to furnish ignition current as well the spark would be weak. After the engine is running, however, this extra drain of starting is not made, and the storage battery and generator are ample for ignition purposes. The dry cells may also be used in emergency, should the other electric apparatus get out of order.

To start the motor, the driver pushes the starting button on the control board and presses down on the clutch pedal. This automatically meshes the teeth of the generator gear with those on the periphery of the flywheel and current is drawn from the storage battery to drive the generator as a motor, thus turning the crankshaft. After the engine is running under its own power, the operator releases the starter button and throws the ignition current switches so that the dry batteries are no longer required. The generator then runs as a generator and supplies ignition current, any excess amount developed being passed to the storage battery, which has a capacity of 80 ampere-hours. The running ignition system is of dual type. A transformer coil is used in connection with it, while the same set of spark-plugs is common for both it and the auxiliary system.

Control Board a Convenience

For lighting, the current is supplied from the storage battery when the motor is not running, but when the engine has attained a speed of about 200 revolutions per minute the generator furnishes the current.

The battery and battery controlling device are located on the right running board, while the generator is on the left rear side of the engine and is driven by inclosed gears.

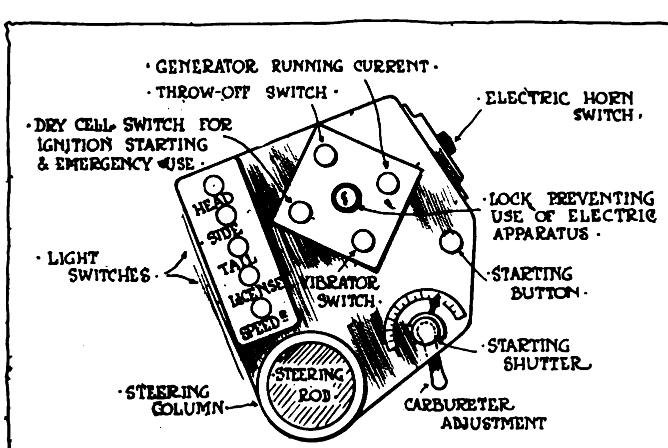

Fig. 3—Plan view of control board located below steering wheel

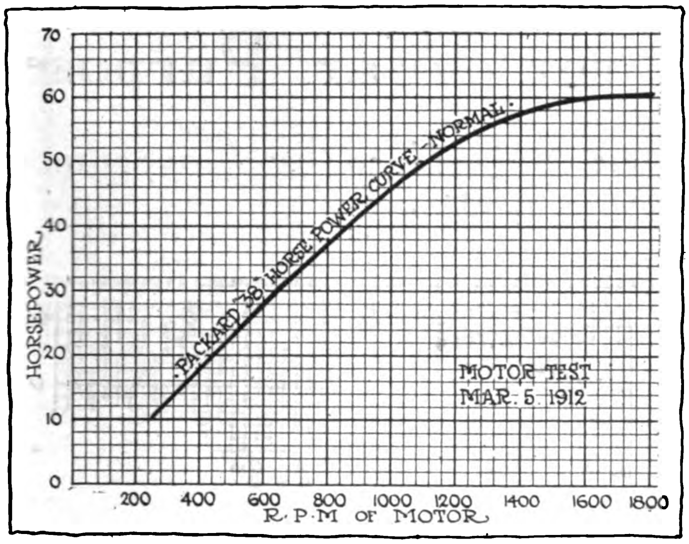

Fig. 4—Chart showing high horsepower developed by Packard 38

A sketch of the control board, which is an entirely new apparatus and never before used on any machine, is given in Fig. 3. It will be seen that every feature of the car's running is brought within easy reach of the driver's hands. It is rigidly fastened to the steering column. This column is stationary, the steering rod turning within it. The location of the control board below the steering wheel is clearly shown in the body illustrations. A single cable running up the steering column carries all the wires from the various electrical apparatus to the switches. Placing these devices here leaves very little on the dash. Speedometer, oil and air pressure gauges and priming buttons are practically all that remain there. The sketch is self-explanatory. A lock is provided so that the car may be protected against indiscriminate use. This lock puts all the electrical connections out of use when desired. A button conveniently located on the dash within reach of the driver's foot is for use in cold weather for priming the cylinders with acetylene gas and thus facilitating starting. Pushing this button injects the gas into the cylinders. For this purpose a special acetylene gas tank is carried, and is seen in the body views at the lower rear corner of the hoods. Referring to the control board sketch, it will be further seen that there is an indicator which shows the relation of air to gas in the carbureter. This carbureter adjustment is operated by a small handle just below the control board and which is seen in the body illustration. The starting shutter button is used to throttle the air supply to the carbureter to facilitate starting the motor. This shutter is operated by pulling up on the button marked.

Motor Differs From Big Six's

The new 38 motor is different from that of the larger six-cylinder Packard car in that it is an L-head type and the valves are all on the right side. The Packard 48 six-cylinder motor is a T-head type. The cylinders are cast in blocks of two each, and another new feature of the 38 design is the complete inclosing of all valve springs by removable cover plates. Since the carbureter is placed on the left side of the motor and the valves on the opposite side, a new form of intake manifold construction is used. This manifold, on leaving the carbureter, passes into three branches and these run between each pair of cylinder castings to the cylinder inlet connections.

As indicated by the model designation, the horsepower rating is 38 according to the S. A. E. formula. The stroke of the new motor is 5 1-2 inches and is the same as that of the larger Packard six. The bore is 4 inches, giving a ratio of 1.375. Referring to the horsepower chart, shown in Fig. 4, it will be seen that the maximum horsepower developed is 60 at about 1,600 revolutions per minute. The rated horsepower of 38 is attained at about 800 revolutions, which appears to be very much below the average power of the motor.

The carbureter on the new six is the same as that of its larger predecessor and is characteristic of Packard design. It is provided with a hydraulic governor which makes use of a diaphragm. The pressure of the water system is directed on one side of this diaphragm, while the other side is connected with the throttle of the carbureter. The greater the speed of the engine, the greater the consequent water pressure on the diaphragm and the greater its outward bulge. By its connection with the throttle, this bulging partially closes the throttle and acts to slow down the motor somewhat, thus performing its function of uniformly governing the motor speed. However, on the new six, while the same governing principle is maintained, the water pump and governor are separate and not combined as in the other model.

The lubrication system is identical in all its principles with that used on the 48 six-cylinder motor. The lubricant is fed by pressure from an eccentrically-driven force pump to all the crankshaft bearings and to the upper and lower bearings of the connecting-rods. In addition to this positive oiling of the bearings, an auxiliary lubricating system connected to the carbureter throttle operate so that when the engine is under heavier load and doing more work, it will get greater supply of oil and vice versa. This auxiliary scheme feeds oil to each of the cylinder walls and the leads from these cylinder openings are connected to the main lubricating system through a check valve. The crankshaft is drilled from end to end to provide a passageway for the lubricant. The lower part of the crankcase furnishes a reservoir for the collection of the oil, from which point it is positively forced by the pump to all the bearings. The splash arrangement which is found in many other American motors is absent in the Packard design.

Fuel Tank Located at Rear

In keeping with the system adopted on its other cars this year, the Packard company has adopted the rear-tank arrangement on the new 38. The gasoline is supplied to the carbureter under about 2-pound pressure maintained by an automatic pressure pump on the motor in connection with a large hand pump on the front seat heel board. This latter is used for the initial pressure. A gauge on the dash indicates the pressure within the tank, while a magnetic gauge on top of the tank tells the supply of fuel contained, the maximum capacity of tanks for all body types being 20 gallons.

The motor is cooled by the conventional system of cellular radiator and centrifugal water pump, located on the left side of the motor and driven by inclosed gears. The cooling fan is belt driven and has a type of belt-tension adjustment. The capacity of the water system is 6 -2 gallons.

The clutch is of multiple disk type, as on the other Packard models. There are five lined driving plates and four steel driven plates. The clutch brake, which is attached to the clutch pedal, aids in gear shifting. The clutch rear bearing is supported by an integral extension of the crankcase and a cover arrangement completely incloses the clutch.

The Packard two-unit principle in which the motor unit comprises the motor and clutch, and the rear axle unit takes in the transmission gears, differential and final drive, is maintained. The power connection between the two units is an amply large drive shaft which is provided with two universal joints. The gearcase bolts by a flange to the rear axle housing. There are three forward speeds and a reverse, the gear-shifting lever having a selective action in the standard form of Packard single quadrant. The gear shift lever and the emergency brake lever are placed at the driver's left, just inside the left front door, to be in keeping with the left-hand steer.

In the new 38 no change from the Packard 48 construction is to be found in any of the running gear features, the frame, brakes, springs and axles presenting the same general appearance in the two cars. The spring sizes are given below:

Front springs: 40 by 2 inches; semi-elliptic.

Rear springs: 51 by 2 inches; three-quarter scroll elliptic.

The frame is of pressed steel, channel section, and arched

France Tests Trucks for War Purposes

Vehicles Not Bought Outright, but Subsidized by Government —Trials Tend to Standardization

Strict Examination Follows 1,558-Mile Road Test, for Which Sixteen Firms Offered Their Latest Models—Economy Considered.

PARIS, Aug. 11—Military France prefers to subsidize privately-owned motor trucks rather than maintain a large fleet of vehicles which can never be fully employed except during general manœuvres or on the outbreak of war. By offering $600 at the time of purchase and $200 for each of three following years it is possible to have at the dispostion of the army whenever needed a very large and perfectly maintained fleet of motor trucks. But before the private owner can enter into the subsidy agreement with the government, the manufacturer must have the type of vehicle approved after strenuous tests on the road and close examination at the hands of technical experts. As new models are brought out every year, these army trials are now an annual event, and as it is to the advantage of every manufacturer to be able to offer his trucks to the public with the possibility of a subsidy, all the latest types of commercial vehicles are found in the trials. Probably, without the public being aware of it, the army has a greater influence in determining design and development of commercial motors than has the private user. Yet the army makes very few direct purchases. It has the first call, however, by reason of the new models being presented to it for test and examination with a view to participation in the subsidy scheme. The army requirements have tended to standardize wheels and tires, bodies and body fittings, under clearance and track; they have made radiator protectors an essential, they have insisted on hooks front and rear for hauling purposes; they have cut down gasoline consumption and arrested oil wastage, and they have done more than the demands of the private user to develop accessibility.

This year's tests have just been brought to a close. They consisted of 1 month under observation, during which the competing vehicles had to make twenty distinct daily runs over routes radiating from Versailles, the total distance covered being 1,558 miles for ordinary trucks, and 1,225 miles when a trailer was hauled.

Spare parts of two cars laid out for inspection

The runs had to be made under full load both singly and in convoy formation, without load, and with gasoline, benzol and alcohol as fuels, the army authorities evidently anticipating a shortage of the usual gasoline supply in time of war. An officer was carried as observer on every vehicle, and very careful control was kept of fuel and oil consumption, for it was on running economy, reliability and absence of wear that awards will be made which will entitle the models to be classed as subsidized types. This year there was no failure on the road; but mere ability to cover the distance is not sufficient, and when the road portion of the trials was over, a very close examination was made of the working parts. This was not a superficial look-over, but consisted of dismounting rear axles, jackshafts, gearboxes, road wheels, motors, steering-gear, etc.

Thirty-two Models in Trials

The French trucks taking part in the trials are really representative of the national industry. This year, for instance, sixteen of the leading home firms entered their latest models, the total number of competing vehicles being sixty-two, representing thirty-two distinct models. Although the army stipulates the body sizes and insists on a certain ratio of dead

---

above the rear axle. It is extended back to protect the gasoline tank and to afford a hanging for it. To allow for a short turning radius the frame is narrowed in front. The front axle is of heavy I-beam section, while the steering knuckles have integrally forged yokes. The rear axle housing is of heavy-gauge pressed steel and it is riveted within flanged collars which are bolted to the internally ribbed aluminum rear-axle housing.

The brakes are of the conventional type of internal and external expanding designs and are of ample size. Bayonet locks are provided on the internal brakes to prevent rattling.

As to the standard equipment which will be furnished with the new six, this includes top and side curtains, top envelope, windshield, electric headlights, combination oil and electric side and rear lamps, license light, horn, tools and tire-repair equipment. All the inclosed bodies are to be fitted with dome lights and switches, speaking tubes and so on. In general, it may be said that while a number of mechanical differences have been incorporated in the new car, the bodies on all Packard cars present similar characteristics.

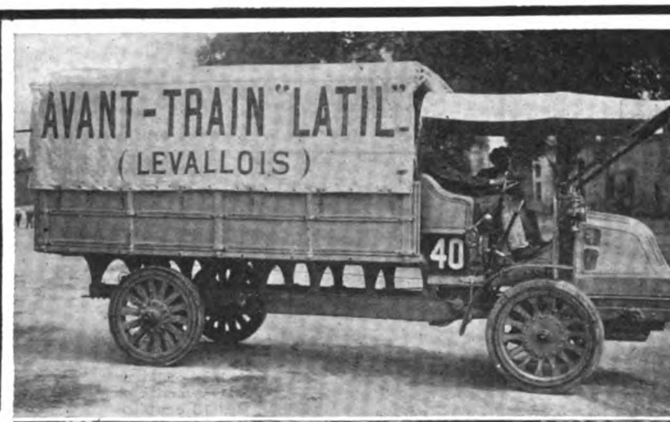
weight to useful load, there is no decided preference for either the motor-under-the-bonnet or the motor-under-the-seat type. This year the bonneted type was in a slight majority, but while certain firms, Saurer at the head of them, claim that the motor should be in front of everything, such leaders as Renault, Berliet, De Dion Bouton, Delahaye, Bayard-Clement, build both types.

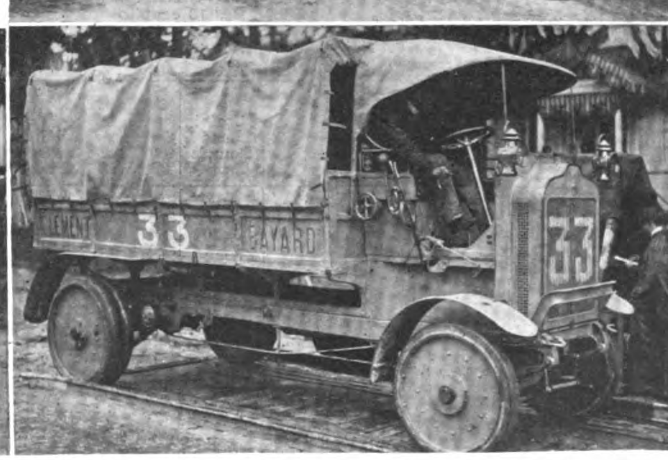
From an American standpoint an important feature of the French trucks is the small size of the power plant. In every case four-cylinder motors were employed, but in only a few cases did the cylinder diameter exceed 4 inches. A very common dimension for 3 to 3 1-2-ton trucks was a cylinder bore of 3 to 3 1-2 inches. There is a tendency, too, to make one type of motor do duty in different chassis designed to carry loads varying from 2 to 3 1-2 tons. The explanation of the small motor can, of course, be found in the high cost of gasoline in France. Last year, in calculating running costs, the price of gasoline was taken at 33 3-10 cents per gallon. This year it is still higher. In motor design there is not any great departure from touring car practice, and except that a lower number of revolutions is aimed at the touring and the truck models hardly differ. For the most part the motors are of the L-type, with fixed point high-tension ignition and either pressure feed or circulating oil systems. The unit system is not favored, being found on only two types: the Latil, which drives to the front wheels, and the new La Buire truck. The Latil is distinctive by reason of a considerable use of bronze alloy castings in place of aluminum, this latter metal being used only for such parts as timing gear housings, oil base, gearbox cover, etc. The Latil motor is a good example of the simplicity that is being aimed at by the French manufacturers. This motor has the valves on one side, the intake, exhaust and water pipes being made in the casting, and while the base for the magneto is made with the crankchamber, there is a flange on one side of the cylinder casting through which is screwed a bolt with locknut to bear on the top of the magneto and hold it to its platform.

Economy Plays Important Part

In the majority of cases the makers apply to the specialist, such as Claudel, Zenith, G. & A., Solex, for their carbureters. The regulations stipulate that gasoline benzol and alcohol shall be used without a change of carbureter. Practically no change is required to use benzol in the place of gasoline, but to properly vaporize alcohol a considerable amount of heat is required. For this purpose nearly all the carbureters are amply water-jacketed, with provision for turning on the flow of water only when required for running on alcohol. The results obtained are not the best, but as alcohol has no commercial use in France for internal combustion motors, the compromise is satisfactory. The rigorous control of lubricating oil and grease in these trials has led to considerable care being exercised to secure economy. Pressure feed to the main bearings and connecting-rod ends and the pump driven circulating system are about equal in numbers. But of equal importance with the actual lubricating system is the necessity of preventing leakages through the tappet guides, crankcase breathers, the ends of the bearings and the joints of the gearbox and rear axle.

Among the new mechanical features shown on the trucks is a special type of frame member employed on the Clement-Bayard chain-driven models. At the point where the jackshaft passes through the frame member the latter is considerably increased in depth, the top line of the frame being straight, but the bottom line given a considerable downward sweep. Thus the total depth of the frame member at this point is about three times that at any point. Obviously this gives increased strength at the point of the frame receiving the bracket for the jackshaft bearings and the forward end of the rear spring. The frame is trussed, the truss rod passing around this downward sweep of the frame. On these models the gearbox is mounted immediately behind the cone clutch, and a propeller shaft carries the drive to the jackshaft. The differential housing is practically of the same type as used on the firm's touring cars, and is bolted to a couple of transverse frame members, one in front of it and one to the rear of it. Unlike some of the smaller models, where the jackshaft is practically of the same design as a touring car rear axle, there is no casing for the two portions of the transverse shaft. Each shaft carries near its outer extremity a brake drum lodged within the face of the frame member, the increased depth at this point making this possible. On some of the other models, notably Delahaye and Peugeot, brakes are fitted at this point, but in both cases the drum is on the outside of the frame, or between the sprocket and the frame. On the Clement-Bayards, with a view to giving accessibility to the brakes, there is a coupling on each half of the jackshaft. All of the Clement-Bayards are fitted with pressed-steel road wheels, this being a type of wheel which up to the present has





The Berliet entry was equipped with rubber tires on the front and steel tires on the rear wheels

Front-drive Latil truck performed satisfactorily

Clement-Bayard truck—note frame construction

One of the trucks submitted by Schneider & Co.

New shaft-driven Saurer truck stood up well

not been considerably adopted in France. During the trials it gave very satisfactory service.

La Buire had in the trials a new 2 1-2-ton model, shaft driven, with canted rear wheels. Unit construction is adopted for the motor and gearbox, the crank chamber having a rearward extension which encircles the disk clutch and has bolted to it the four-speed gearbox. On an extension of the propeller shaft, to the rear of the axle, the foot-operated brake is mounted, the hand brakes being in the usual position on the road wheels. A double reduction is employed in the rear axle; this consists of two spur pinions, one of which is mounted on the same shaft as the crown bevel wheel, and the other on the differential shaft. In principle, though not in the same detail, this has been adopted by several other French firms for both touring and commercial models. These trucks are also fitted with oscillating hubs for the steering wheels. This invention, while giving perfect lateral stability, allows the wheel to articulate in a vertical plane. It consists of a central hub, with the wheel revolving on a centrally-located pin attached in the usual position, but being mounted on the stub axle below the main journal. The result is that the weight of the vehicle is carried by the wheel below the main journal, leaving the wheel free to articulate in a vertical plane about this lower suspension. Briefly, the construction of the wheel consists of a steel hub pierced in its center for the passage of the axle pin. The spokes are mounted on this hub in the usual way, and in the interior of the hub is a single steel plate bored to provide two distinct bearings; the upper one is the axis of rotation, the lower one receives the stub axle and is the axis of oscillation. The wheel, which is the invention of M. Genillon, appeared to give satisfactory service in the trials. The usual type of muffler was not fitted on the La Buire cars. In its place there is a long, big-diameter pipe—probably 3 inches in diameter—attached just below and slightly within the frame member, and terminating in a small-diameter pipe discharging at the rear.

Saurer competed with a shaft-driven model, the vehicle being a new 2-ton truck, but all the larger types were retained with side chains. Shaft drive was in a decided minority, the firms adopting it being Schneider, who builds most of the Paris buses; De Dion Bouton, La Buire, Berliet for one model only, and Renault. At the end of the Renault shaft a bevel pinion meshes with a crown bevel wheel carrying on its shaft a spur pinion engaging with a larger spur pinion on the end of the left-hand axle shaft. On the continuation of the propeller shaft, to the rear of the differential, there is a second bevel pinion meshing with another crown bevel wheel, also carrying on its shaft a spur pinion in engagement with a larger pinion mounted on the extremity of the right-hand axle shaft. Obviously, the two extremities of the forged axle are bored out to receive the drive shafts. Instead of the usual type of spring shackle, Renault makes use of a sliding block, consisting of a hanger bolted to the lower side of the frame member and having two grooves into which the sliding piece mounted on the shackle bolt is received.

Many Steel Tires in Evidence

Serious attempts have been made by French makers to abolish use of rubber tires for commercial vehicles, and in the army competition the use of steel rims gives a decided advantage, for the cost of the wear and tear of tires is estimated by the jury, and this cost must always be lower for steel than for rubber ones. Steel-shod wheels, however, were present in smaller numbers than usual, and no vehicle came successfully through the trials with steel rims on all four wheels. In a number of cases the front wheels were shod with rubber and the rear ones fitted with steel tires, Delahaye, Berliet and Latil adopting this combination. This latter firm, having the entire power plant over the front axle, there being no mechanism to the rear of the driver's seat, was fully justified in employing steel-shod wheels at the rear, but in other cases the results were not satisfactory. When running without load the temptation was to speed, with the result that the vehicles danced about on the road, play set up in the spokes of the wheels and the mechanism suffered. Wheels are still the weakest point of the trucks, many having had to be patched up on the road in order to complete the test. In a few cases tires gave way, breaking up completely and having to be changed. Spare rubber tires had to be carried, their weight being considered as useful load, whereas all other spares were weighed in with the empty vehicle, but as in most cases it was not possible to fit them without the use of a hydrau-

OFFICIAL OPERATING COSTS OF FRENCH TRUCKS HAVING QUALIFIED IN 1911 ARMY TRIALS UNDER THE SUBSIDY SCHEME

The cost of operating was based on fuel at the following prices:

Lubricating oil	58 1-2	cents per gallon.
Grease	8 1-5	cents per pound.
Gasoline	33 3-10	cents per gallon.
Benzol	22 1-5	cents per gallon.
Alcohol	36	cents per gallon.

Cost is given in francs. About three-quarters of distance was covered under the full load and one-quarter empty. No account is taken of tire wear. The kilometer is, roughly, 5-8 mile. The franc is 20 cents.

Shaft-driven De Dion Bouton truck

Renault entry, which had a distinctive drive

lic press it was difficult to see their utility aboard. Torrihon had a system by which it was claimed that tires could be changed on the road, this consisting of a detachable rim with studs on its inner face passing into grooves on the fixed rim. The same firm had also a quick-detachable arrangement consisting of a U-section fixed rim on which the ordinary rubber tire was mounted and secured in position by means of four circular section rings—two on each side—levered into position in much the same way as a pneumatic tire is levered over its rim. Put into position, these rings filled up the space between the walls of the fixed rim and the rubber bandage, and entering into a groove on this latter prevented it being pulled off. Rubber block tires were not admitted by the army authorities. Metal wheels did not find much favor among the French manufacturers. Clement-Bayard made use of pressed-steel wheels; Peugeot had tubular cast-steel wheels, but all the others had heavy artillery wood type. In some cases an extended flange was given the steel rim, with the object of protecting the walls of the rubber tire.

Calendar of Coming Automobile Events

Shows, Conventions, Etc.

Aug. 24-Sept. 9....Toronto, Can., Display of Automobiles, etc., at Canadian National Exhibition, Transportation Building.
Sept. 17-20........Denver, Col., Convention International Association of Fire Engineers.
Sept. 23-Oct. 3....New York City, Rubber Show, Grand Central Palace.
Dec. 7-22..........Paris, France, Paris Automobile Show, Grand Palais.
Jan. 4-11..........Cleveland, O., Annual Automobile Show.
Jan. 11-25, 1913...New York City, Thirteenth Annual Show, Madison Square Garden and Grand Central Palace, Automobile Board of Trade.
Jan. 20-25.........Philadelphia, Pa., Annual Automobile Show.
Jan. 27-Feb. 1.....Detroit, Mich., Annual Automobile Show.
Feb. 1-8...........Chicago, Ill., Annual Automobile Show.
Feb. 10-15.........Minneapolis, Minn., Annual Automobile Show.
Feb. 17-22.........Kansas City, Kan., Annual Automobile Show.
Feb. 24-March 1...St. Louis, Mo., Annual Automobile Show.
March 3-8..........Pittsburgh, Pa., Annual Automobile Show.
March 8-15.........Boston, Mass., Annual Automobile Show.
March 17-22........Buffalo, N. Y., Annual Automobile Show.
March 19-23........Boston, Mass., Annual Truck Show.
March 24-29........Indianapolis, Ind., Annual Automobile Show.

Race Meets, Runs, Hill Climbs, Etc.

Aug. 30-31........Elgin, Ill., Road Races, Chicago Automobile Club and Elgin Automobile Road Racing Association.
Sept. 1-2..........St. Louis, Mo., Track Races, Universal Exposition Company.
Sept. 2..........Indianapolis, Ind., Speedway Meet.
Sept. 2..........Winnipeg, Man., Track Meet.
Sept. 3-6........Chicago, Ill., Commercial Vehicle Reliability Run, Chicago Motor Club.
Sept. 11-14........Buffalo, N. Y., Third Annual Reliability Tour, Automobile Club of Buffalo.
Sept. 17...........Milwaukee, Wis., Grand Prize Race.
Sept. 20...........Milwaukee, Wis., Wisconsin Challenge and Pabst Trophy Races.
Sept. 21...........Milwaukee, Wis., Vanderbilt Cup Race.
Sept. ....Washington, D. C., Reliability Run, Automobile Club of Washington.
Oct. 7-11..........Chicago, Ill., Reliability Run, Chicago Motor Club.
Oct. 12...........Salem, N. H., Track Meet, Rockingham Park.
Nov. 6............Shreveport, La., Track Meet, Shreveport Automobile Club.

Scene in Minneapolis just before the start of the annual tour of the Minnesota State Automobile Association for Winnipeg

Seven Clean in Winnipeg

Annual Tour of Minnesota State Automobile Association Meets with Rain and Bad Roads

Running Schedule Twice Lowered—Tour Expected to Result in Big Business

WINNIPEG, MAN., Aug. 11—Minnesotans in their fourth annual reliability tour, after three days of road experience have found that northern Minnesota soil and that of Manitoba may be right to raise grain, but that it is not designed for touring after a rain. The running schedule has twice been cut 2 miles an hour all around.

The start was made Thursday morning from the Automobile Club of Minneapolis with nine contesting cars and two non-competing. One of the former, the Staver-Chicago, withdrew at Hallock Saturday afternoon, due to trouble with the steering gear and other slight difficulties, but expects to pick up the trail at the American border tomorrow. The McFarlan and Cutting entries failed to check out. The Packard non-contesting car is at Hallock with gear stripped and differential housing wrecked. The Stoddard-Knight pacemaker car, after a series of slight accidents to tires and fenders, cracked its crankcase over a railroad track 3 miles east of Red Lake Falls. The hole was patched and the pacemaker resumed the lead the following day.

Road work galore was encountered the first day and the run therefore was slow. Tire trouble was the main hazard for the second day which ended for the night at Thief River Falls. The noon control was made at the home of a half-breed Indian family where luncheon was served by descendants of the Ojibways.

On the third day the gumbo had dried and left ruts deep and hard, and the mire was so deep at points that it engaged the radius rods on the front of the runabout class cars, and even touched the hubs of the touring machines. The result was slow running and a necessity for detouring along the right of way of the Great Northern road.

When the border line was reached, the Canadians' custom officials were induced to allow the foreigners to enter at slight cost.

The trip is expected to be a great sales tour for the medium and low-priced car dealer and manufacturer. Following is the list of entries, with the first day penalties:

No.	Car	Driver	Division	Penalty
	CLASS E, GRADE III			
1	Marmon	Bohn Fawkes	5	0
2	Hupmobile	Warren Munzer	2	0
3	Studebaker 20	William Soules	1	9
5	Cadillac	A. Zekman	3	0
7	Mitchell	George Murphy	4	—
8	Paige-Detroit	Ed. Fox	2	9
9	Warren-Detroit	Harry Rockelman	2	0
10	Staver	Noah Moss	5	withdrawn
11	Reo V	N. Bass		0
	NON-CONTESTANTS, GRADE IV			
12	Buick	H. G. Blanchard	2	0
13	Packard	Charles Smith	7	0

Chicagoans Stopped by Rain

CHICAGO, Aug. 12—Torrents of rain, coupled with reports of wretched road conditions, caused the abandonment of the second annual team match between the amateurs and tradesmen of the Chicago Motor Club after half of it had been run. Nine amateurs and ten tradesmen started in the match which left Chicago last Thursday morning for St. Joseph, Mich. The run over, 118 miles, was made easily, the weather being good, but the roads in Michigan sandy. At the end of the first half of the match the amateurs had only 3 points against their team, while the tradesmen were loaded down with 170, the bulk of them coming because one of the cars came in after the 2-hour limit, the delay being caused by tire trouble.

Making Plans for Elgin

Entry List Growing Daily, and Fields for The Five Events on the Card Will Be Well Filled

Tetzlaff's Fiat in Elgin Trophy and Free-for-All Races—Mercedes Also Entered

CHICAGOfi, Aug. 12—Prospects for the annual Elgin road races are bright indeed. The entry list continues to grow daily and it looks now as if the field would be made up of a fast lot of cars, including several of foreign make.

Teddy Tetzlaff, holder of the world's road record, reached Chicago Saturday and signed blanks which book him for competition in both the Elgin trophy and the free-for-all on the second day of the meet. He is to drive the smaller Fiat which he handled at Indianapolis. Tetzlaff states that E. E. Hewlett, his backer, will send on the grand prix Fiat for the free-for-all, which will be driven by Dave Lewis, another California star.

A Mercedes also has been dropped into the speed battle, the entry of George Clark having been secured at Galveston by representatives of the Chicago Automobile Club. Clark intends following Tetzlaff's example and will run in both races on the second day.

One entry has been booked for the race for cars 230 inches and under, which was added to the card last week, the nomination coming from F. S. Duesenberg, who has declared the little Mason which did so well in the last Algonquin hill-climb. Bill Endicott is to drive the car.

Heavy rains the past few days have delayed the work on the course, but it is expected that within a day or so half a dozen gangs of men will get busy making the repairs which are needed. The military has been secured and now there seems to be no stumbling block in the way of the promoters.

Atlanta, Ga., Aug. 7—The idea, novel in the South at least, of a 1-day tour within the confines of a single county was given a work-out here today when the 1-Day-Route Around Fulton County, Ga., was dedicated.

Of the thirty-two cars entered twenty-five started and sixteen finished. That no more finished is due to the fact that in the 125-mile route there were virtually 10 miles of clay road.

Electric Pathfinder Fighting Mud

LORETTA, TENN., Aug. 11—After three days of excessively heavy rain in this section the official pathfinder of the American Automobile Association tour of 1912, a Flanders electric, reached this place over roads that are deep in mud and almost tractionless. The route being picked out will be known as the Jackson Highway and in one of the counties traversed today $200,000 will be expended in improvements before the tour itself passes.

The pathfinder has covered the route from Louisville to Loretta during the past week, touching at Mammoth Cave, Nashville, Bristol and Columbia, bringing the total distance to 799 miles.

It was found that the Bristol road was impracticable because of the numerous ferriages necessary and the lack of facilities for such transport.

Tomorrow's course is toward Memphis, but cutting across the northern end of Alabama and Mississippi, touching Sheffield, Florence and Corinth before swinging north to Memphis.

Transcontinental Alco's Progress

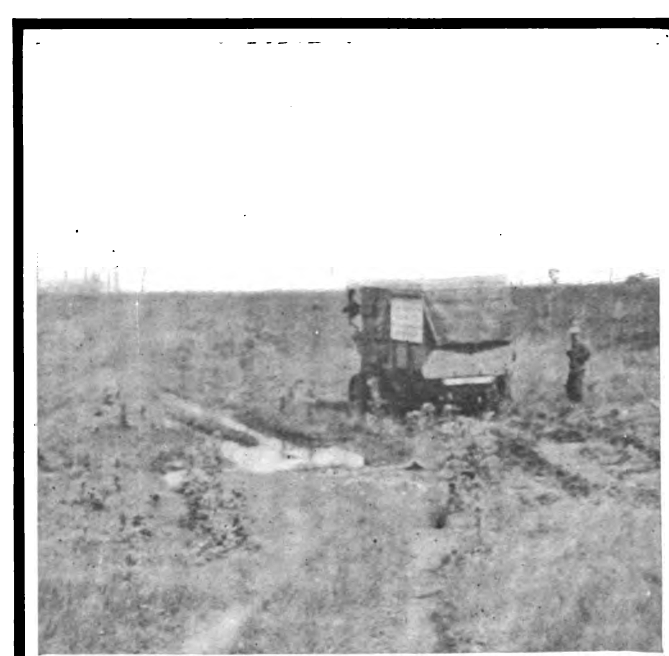
POINT OF ROCKS, WYO., Aug. 10—The trip of the Transcontinental Alco truck is just one flood after another, according to advices received here from the crew.

Just as the motor freighter, which is now engaged in the first delivery of merchandise from one end of the country to the other, was going well after experiencing ten cloudbursts in 8 days, it ran into another heavy rainstorm that hung it up along with four transcontinental touring parties and two prairie schooner outfits.

Reports from the Wyoming country are to the effect that floods are worse at this time than in 14 years and travel by motor through certain sections has been made impossible by the conditions of the road. Trails are both impassable and invisible.

From latest information the Alco truck is on its way towards Evanston, Wyo., where it is taking a trail towards Salt Lake City; from there the route will lead to Reno, San Francisco and Petaluma, Cal., where the load of merchandise will be delivered.

Flanders electric A. A. A. pathfinder crossing to Columbus, Ind.



Trail of Transcontinental Alco truck after a heavy rain

Developing Export Trade

Major Points of Consideration

THE export trade offers a fruitful field to the American automobile maker owing to the widespread use of the motor vehicle in such continents as South America, Africa and Australia and parts of Asia. In every one of these territories the European maker obtained a leading advantage due to his being several years earlier in the manufacturing field than our big organizations and to the fact that when their home field was apparently surfeited, American makers were having the utmost difficulty in filling orders and meeting urgent demands. With such a condition of market saturation in Europe and so healthy a demand here, there was little hope for other conditions than those which happened: namely, that European makers should start rigorously the development of the foreign field and that American makers should give every attention to satisfying the home demand. In this way Europe gained a position of precedence in the foreign field, a position she has constantly strengthened ever since and a position which the American builder has been valiantly attacking during the last 2 years.

The European maker has been longer schooled in the export trade than many of our builders and consequently while his work may have been slower it has also been surer and on a more permanent basis. Not a few of our concerns which have shown particular aggression have laid themselves open to criticism by their entire disregard for local conditions in the countries to which they have exported their cars and also by some of the tactics pursued. When doing business in a foreign clime it is essential to meet the citizen of that land in his own business way. If he has his characteristic way of opening trade negotiations, they may appear antiquated; the aggressive American export man may consider them quite at variance with home methods, but they are his ways of doing business. This is imperative until a business friendship extending over some years has been made, by which time the foreigner will have learned to rely on the export man, will have learned to depend on his goods, will have become acquainted with his various business methods, and in a word, will have become thoroughly satisfied that his ways are just, his intentions always to do right and his commodities dependable.

Some of the American builders have shown excellent judgment in developing their export trade. They have not set out with a large consignment of cars, some of questionable vintage, with larger advertising appropriations and masses of literature; rather their course has been one of conservatism. They have opened up headquarters, perhaps 2, 3 or even 4 years before they made any effort to carry cars on hand for sale and immediate delivery. They carried stocks of spare parts for all who might be touring in those countries. They sold machines on photographs, blue prints and performances. The citizens of the country were impressed with the fact that these concerns were to be trusted, that they had confidence in their goods and that they could be expected to stand firmly back of their product, irrespective of the quarter of the globe in which it might be sold.

Other American houses took equally judicious courses. They established assembly factories, made real estate investments and stocked well up with repair parts when starting to do business. The result was only as could be expected: The business grew and flourished, because the method of attack engendered confidence in the people. The people recognized that they were not purchasing from some concern that would be here to-day and gone to-morrow. They realized that if their car remained in commission for 10 years or longer there was good opportunity that the supply of spare parts and the factor of attention that the consumer would receive would be as great as at the present time.

Contrast with these methods those of the concern that engages the so-called export expert who hopes to stampede the people into his product. His advertising appropriations are enormous compared with the value of the commodity he has to sell. His supply of spare parts is amazingly small, his cars in some cases are carried-over models, and his prices have been raised as high as 100 per cent. over the American price. He hopes to storm the citadel, to make conquests in a day or a week and to establish a broad export trade in 3 or 6 months at the outside. The result is that at the end of that period he returns, some of his cars sold, the remainder left with some not-too-dependable organization, the advertising appropriation exhausted, the home company dissatisfied and the export trade manacled at the start.

Big Crops Are Assured

Reports as of August 1 Indicate Enormous Harvests of the Cereals Throughout the Country.

WASHINGTON, D. C., Aug. 12—Bumper crops are assured, according to the August crop report of the United States government, and in all probability the actual harvest will be larger than those indicated by the official figures. The estimates are dated August 1 and in the days that have intervened since then favorable progress has been made in all lines of agriculture. Perfect crop weather has been experienced and much improvement must have occurred since the first of the month.

The government figures show that the yield of winter wheat has been an average of 15.1 bushels to the acre and while the acreage is smaller than last year by 5,623,000, the average yield is .6 bushel larger per acre, bringing the official estimate of the yield to 390,000,000 bushels. This is 64,000,000 bushels smaller than last year in the departmental estimate. That the estimate for 1911 is too high and that of 1912 too low is generally admitted. The official figures of last year have been revised to conform with the data secured by the census bureau which reduces the acreage to 29,162,000 and the yield to 430,000,000. A report received from the Kansas Bureau of Agriculture shows that in that state alone the official figures for this year as to winter wheat acreage are 600,000 acres too low. This would account for a difference of 11,000,000 bushels of wheat in Kansas. Thus, according to close students of the situation, the weight of probability points to a yield of winter wheat not far from 400,000,000 bushels, with the chances favoring a larger yield rather than a smaller.

The condition of spring wheat is placed at 90.4, a gain of 1.1 since July 1. Since August 1 the condition has improved materially. Last year the yield of spring wheat was 190,000,000 bushels. The August 1 report indicates a yield of 290,000,000 bushels and the favorable weather during the early part of this month when spring wheat is in the final stage of ripening makes it certain that the total yield will be larger.

The corn crop is estimated at 2,811,000,000 bushels, a decrease in condition of 1.5 points since July 1. Oklahoma makes the poorest showing in corn this season with a condition of 65, against a 10-year average of 76. Iowa, a huge producer, has a condition estimated at 89, against a 10-year average of 83. Oats crop is in splendid condition all over the country.

Summarized, the grain crops of the country are estimated by the government to be about as follows:

Grain	Acreage	Estimated yield	Condition
Winter wheat	25,744,000	390,000,000	...
Spring wheat	19,201,000	290,000,000	90.4
Corn	108,110,000	2,811,000,000	80.
Oats	37,844,000	1,207,000,000	90.3
Other crops, except cotton	17,900,000	675,000,000	...
		Tons	
Hay	49,209,000	73,000,000	...
Totals compared with last year:			
	1912	1911	
Grain and crops	5,373,000,000	4,616,000,000	
Hay, tons	73,000,000	47,000,000	

The difference in money value is in the neighborhood of $1,200,000,000 in favor of the current season.

Made His Own License Plates

LOCKPORT, N. Y., Aug. 12—Albert Dussault, of the Dussault Garage, of this city, will be given a hearing on Friday in Police Court on charge of faking New York state license numbers on the plates of his automobiles. It is claimed that Dussault painted over last year's plates with numbers he secured from the state's automobile bureau at Buffalo, and that the prisoner has several similar sets of numbers in use throughout the city.

Boston Booms Electrics

Business Men of the Hub to be Convinced of Utility of Commercial Vehicles of that Type

BOSTON, MASS., Aug. 10—An independent trucking system using electric vehicles exclusively and competing with the horse-drawn vehicles now in use by the majority of the trucking firms of Boston is the latest recommendation from the special committee of the Electric Vehicle Club of Boston appointed to look after business problems. The principal object of the contemplated move is the education of the business men in the growth, durability and economical operation of the electric vehicle, although it is believed that the company will be self-supporting and will later on be purchased by private individuals or a corporation when its success has been fully demonstrated. The avowed intention of the committee is to compete actively with teamsters with a view to increasing local sales of electric vehicles among this class of prospective customers as well as among the large corporations doing their own transportation.

In detail, the project that has been laid before the club by a special committee appointed to devise ways and means for promoting the sale of electric commercial cars in Boston, calls for the organization of a $100,000 company under the auspices of the commercial section of the club. Not less than one-half of the stock is to be subscribed or raised by truck, tire, battery and other interested concerns, subscriptions to be payable either in cash or in suitable equipment.

W. E. Eldridge, representing the Couple-Gear Company, is chairman of the committee which formulated the plan. The other members are: J. Walter Emery, Walker Vehicle Company; B. A. Tirrill, Commercial Truck Company; N. Rommelfenger, Detroit Electric Car Company; R. F. Ketchum, General Motors Truck Company; J. W. Bowman, Waverley Company; H. E. Taylor, Lansden Electric Company; Frank N. Phelps, Baker Motor Vehicle Company.

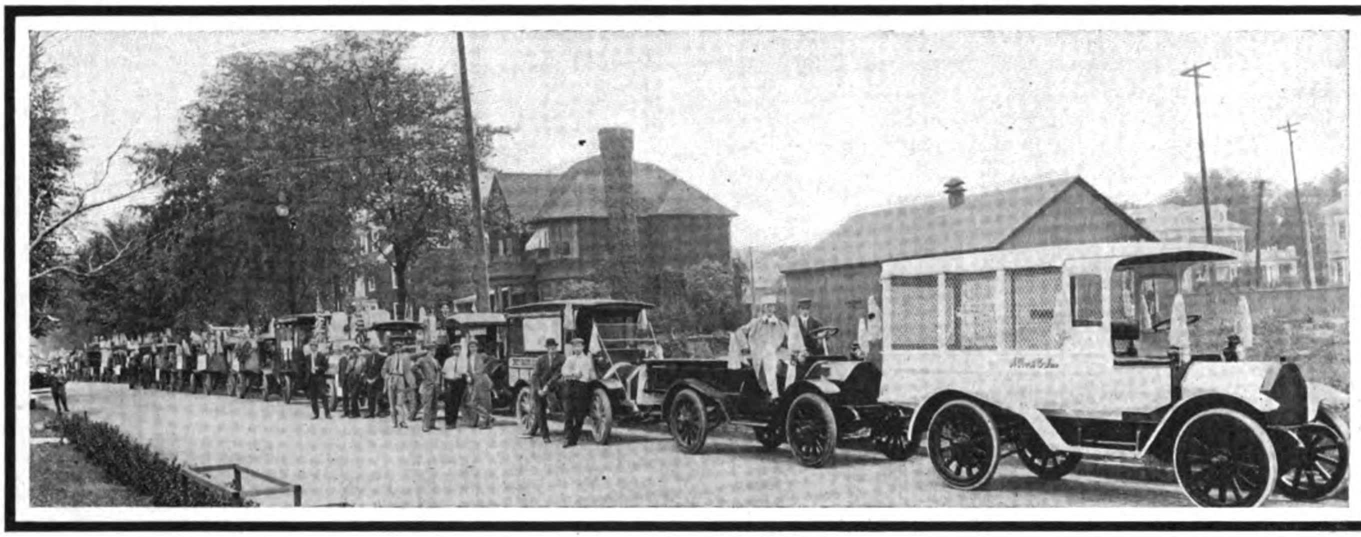
"It is estimated that two-thirds of the horses operating in and around Boston are owned by professional teaming contractors and expressmen," reported the committee in presenting its plan. "The reason for this is that the service required in the transportation departments of many of the merchants and manufacturers having hauling to do is intermittent. They need several trucks today—and perhaps only one tomorrow. More service must be had during busy seasons than dull.

"It therefore would seem that the coming of the electric truck is likely to make much change in the percentage of the total hauling now done by the professional contractors.

"The merchants or manufacturers who will buy the electric trucks and wagons will be only those who have steady work for them. The bulk of the work in Boston will continue to be done by vehicles kept for hire. When the complete change from horses to motor vehicles has been made, the majority of the equipment is likely to be owned by those of the now existing teamsters whose foresight and finances admit of the adoption of the new ways, or more likely by large motor trucking service corporations financed from entirely new sources. If these are the conditions—how shall we confront them?"

Goggles Duty, 1 3-8 Cents per Pound

WASHINGTON, D. C., Aug. 12—The board of general appraisers recently rendered a decision wherein it was held that certain so-called motor goggles, which were assessed with duty at 10 cents per dozen pairs and 45 per cent. ad valorem, under paragraph 106 of the tariff act, were properly dutiable at 1 3-8 cents per pound and 5 per cent. ad valorem under paragraphs 90 and 104 of said act.



Showing sixty Federal trucks in line in the recent Cadillaqua parade in Detroit, led by a shining, white delivery wagon

MANY Federal Trucks in Line—In the recent Cadillaqua parade in Detroit there were many commercial vehicles to swell the number of automobiles to 5,000 as well as pleasure cars. The Federal contingent numbered sixty trucks of many styles, ranging from the heaviest type of truck made by the concern to its lightest delivery model.

After the Cut-Outs—The City Council of Coshocton, O., has adopted an ordinance against the use of the muffler cut-out.

Oakland Branch in Cleveland—In furtherance of the new sales policy of the Oakland Motor Company, a factory branch has been opened in Cleveland, O., where this car will be handled exclusively.

Tyler Goes to Marion—C. H. Tyler, former manager of the United Motor Cleveland Company, Cleveland, O.. signed to become special representative of the Marion Motor Car Company in the Central West.

Lloyd to Leave Velie—George H. Lloyd, who has been sales manager at the factory of the Velie Motor Vehicle Company since 1908, has announced his retirement. He has not yet made any plans for the future.

Griffith Joins Ohio Electric—Warren E. Griffith has accepted a position as assistant sales manager for the Ohio Electric Car Company, Toledo, O. Owing to the increased business of this concern it was found necessary to branch out in its sales department.

Undertaker Makes Innovation—With the purchase of a Peerless hearse, ten Reo limousines, a Peerless casket wagon and an embalmer's runabout a New Orleans, La., undertaking establishment has gone on a motor basis. One of the peculiar local customs in New Orleans is the pomp observed at funerals.

Auto License Plates Expensive—The automobile license plates for 1913 will cost New York state $27,150, or at the rate of 30 cents a pair, which will make the amount $30,000 if the registration figures reach 100,000, as expected. The plates are to be finished in baked enamel. The contract was awarded to the Manhattan Supply Company, of New York.

Absorbs Transfer Company—As a result of a deal consummated the past week the Seattle, Wash., Taxicab Company has absorbed the baggage and passenger business of the Seattle Transfer Company. The name of the Seattle Taxicab Company has been changed to the Seattle Taxicab & Transfer Company. A motor service will be installed in all departments of the new business.

Willys Heavily Insured—President John N. Willys, of the Willys-Overland Automobile Company is the most heavily insured man in Toledo, O. He carries $500,000 for which his wife in beneficiary; $500,000 to be paid at his death to his child; $500,000 in favor of the Willys-Overland company, and $300,000 which he carried before taking out the three other policies. Mr. Willys carries in all $1,800,000 insurance on his life.

Motz Branch in Pittsburgh—A factory branch of the Motz Tire & Rubber Company, of Akron, O., has been opened in Pittsburgh, Pa. The new branch has been made necessary by a large increase in the use of the Motz double-notch tread cushion tire in this district. It is equipped to give a complete service to the users of these tires, and is now operating with a full corps of workmen and tire experts. S. H. Fronsdorf is in charge.

Canada Exporting Cars—When the Rakala of the New Zealand Shipping Company sails for Auckland and other Antipodean ports this week she will carry among other items of general cargon 180 Canadian automobiles, worth approximately $250,000. The Whakatane sailed from Montreal 6 weeks ago with 280 automobiles on board, while one of the Elder Dempster liners, the Ninina, leaving Montreal a month ago carried 100 or more cars to South Africa.

Dr. McClure in Charge—Merging the United States Motor Company's interests places Dr. F. E. McClure in charge of the marketing of all of the company's products in the Cleveland, O., district. He retains the management of the States Cleveland Motor Company, which handles the Stoddard-Dayton, Brush and Currier cars, and, in addition, will have charge of the marketing of Columbia and Maxwell, which the United Motor Cleveland Company markets.
